THE AMERICAN MATHEMATICAL MONTHLY

(FOUNDED IN 1894 BY BENJAMIN F. FINKEL)

R. A. ROSENBAUM, *Editor*

EDITORIAL CORRESPONDENCE AND MANUSCRIPTS OF PAPERS should be addressed to the Editor, R. A. Rosenbaum, Wesleyan University, Middletown, Conn. 06457.

ADVERTISING CORRESPONDENCE should be addressed to RAOUL HAILPERN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

NOTICE OF CHANGE OF ADDRESS by members of the Association as well as correspondence regarding subscriptions to the MONTHLY should be sent to the Executive Director, H. M. GEHMAN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

THIS IS THE OFFICIAL JOURNAL OF THE

MATHEMATICAL ASSOCIATION OF AMERICA, INC.

(Devoted to the Interests of Collegiate Mathematics)

General Office: SUNY at Buffalo, Buffalo, N. Y. 14214. *Executive Director:* H. M. GEHMAN

OFFICERS OF THE ASSOCIATION

President, R. L. WILDER, University of Michigan
President-Elect, E. E. MOISE, Harvard University
First Vice-President, G. S. YOUNG, Tulane University
Second Vice-President, A. B. WILLCOX, Amherst College
Editor, F. A. FICKEN, New York University
Secretary, H. L. ALDER, University of California, Davis
Treasurer, H. M. GEHMAN, State University of New York at Buffalo
Associate Secretary, RAOUL HAILPERN, State University of New York at Buffalo

Additional Members of the Board of Governors: C. B. ALLENDOERFER, J. J. ANDREWS, DOROTHY L. BERNSTEIN, R. H. BING, D. W. BLAKESLEE, E. A. CAMERON, E. J. CAMP, D. E. CHRISTIE, HARVEY COHN, R. B. DEAL, ROY DUBISCH, WADE ELLIS, K. W. FOLLEY, CALVIN FOREMAN, EMIL GROSSWALD, R. C. JAMES, P. S. JONES, D. E. KIBBEY, A. T. LONSETH, K. O. MAY, L. F. MCAULEY, D. W. MILLER, J. M. H. OLMSTED, C. R. PHELPS, G. B. PRICE, P. K. REES, R. A. ROSENBAUM, ABRAHAM SCHWARTZ, L. L. SCOTT, M. F. SMILEY, F. M. STEIN, A. F. STREHLER, A. W. TUCKER, C. J. VANDERLIN, JR., D. W. WALL, J. R. WESSON, G. N. WOLLAN, MARTIN WRIGHT.

Annual dues for members of the Association (including a subscription to the American Mathematical Monthly) are $6.00. For nonmembers the subscription price is $10.00.

PUBLISHED BY THE ASSOCIATION at Menasha, Wisconsin, and Buffalo, N. Y.
during the months of January, February, March, April, May, June–July, August–September, October, November, December.

Second-class postage paid at Menasha, Wisconsin. Acceptance for mailing at special rate of postage provided for in the Act of February 28, 1925, embodied in Paragraph 4, Section 538, P. L. and R., authorized April 1, 1926.

AWARD FOR DISTINGUISHED SERVICE TO PROFESSOR WILLIAM LARKIN DUREN, JR.

Service to mathematics, whether distinguished or not, is a metaphor. Mathematics is an abstraction, and when we say that something is done for the benefit of mathematics we are speaking figuratively and giving an abstraction and interpretation of the motives for the action. But service to people who want to learn mathematics, or to teach mathematics, or to advance mathematics, or to use mathematics, is no metaphor. Each of these services stands as a responsibility before all those who have the capacity to perform them, and the degree to which the responsibility is accepted depends heavily on the degree to which one feels himself to be a part of a community of human beings in whose lives mathematics plays an important role.

William Larkin Duren, Jr. is one who has always accepted the responsibility for such services, not with resignation but willingly. And when this drive toward helpfulness to the mathematical community is coupled with ability and tenacity such as his, the natural outcome is truly distinguished service to mathematics.

After receiving his B.A. and M.S. degrees from Tulane University, and in 1930 his doctorate from the University of Chicago, Duren taught for a year at what is now Wayne State University and then rejoined the faculty at Tulane University for twenty-four years, but not uninterruptedly. From 1943 to 1945 he served as Operations Analyst with the U. S. Army Air Force. In 1948 he became chairman of the Department of Mathematics at Tulane, and by his good management and his consciousness of the opportunities present in the rapidly changing scene of the early 1950's he greatly raised the stature of the department.

He had already served some users of mathematics by his work during the war; in 1953 he served the advancers of mathematics by becoming the first Program Director in the Mathematical Sciences in the National Science Foundation. This he followed by a sort of Toynbee pattern of "withdrawal and return"; in the year 1953–54, holding a Ford Foundation Faculty Fellowship, he visited a number of universities to try to diagnose the troubles that were clearly besetting mathematical education, and to decide how he could most effectively help in the remedying of them.

One serious trouble, immediately apparent to any active mathematician who considered the matter, was that undergraduate instruction had stagnated for about half a century, unaffected by the radical changes at the research level. As a matter of fact, there had been several efforts to improve the undergraduate program, but being local these could not overcome the inertia of the vast bulk of institutions. Effective reform demanded a broader base. In January of 1953 Duren convinced the then President of the Mathematical Association of Amer-

WILLIAM LARKIN DUREN, JR.

ica of the need of appointing a committee to consider the problems of making available in our society the values of modern mathematics. This was the beginning of the Committee on the Undergraduate Program, better known as the CUP or as the Duren committee, since appropriately Duren was its chairman. With a less dynamic chairman the CUP might have turned out a description of a desirable curriculum, with a proposed list of topics for each course, to be commended in principle and ignored in practice. But Duren wanted none of that. Instead, the committee outlined a system of courses in mathematics involving some rather radical changes, and then showed that the proposals were not merely utopian by producing a collection of text-books on which the proposed courses could be based—all of this in a time when liberal support for course-improvement projects was merely an optimist's dream. For four of the six years Duren was chairman of CUP; for the other two he was ineligible, being President of the Association, but he did most of the chairman's work anyhow.

After six years it was clear that many aspects of mathematical education, such for example as programs for small colleges and programs for training teachers, needed careful study, so at the request of CUP it was dissolved and a larger group, the CUPM, with a broader charge, was constituted. This gave Duren a five-year respite from this particular activity, until he returned to serve as chairman of CUPM during 1963–65.

A complete list of the committees and panels on which Duren has served, if such a list could be compiled, would be long indeed. Frequently he has been asked to speak at conferences on mathematical education, and not in this country alone; he was one of the four American speakers at the Japan-U. S. Conference on Collegiate Mathematical Education held at Katada (near Kyoto) in 1964, and was the only American mathematician at the US-AID-NSF-Gov't. of India Conference on Science Education in India, held in Srinagar in the summer of 1966. He has served as a National Science Foundation College Visitor-Lecturer. He served as Dean of the College of Arts and Sciences of the University of Virginia from 1955 to 1962, and since then, as University Professor, he has helped with the creation of the Department of Applied Mathematics and Computer Science in the School of Engineering and Applied Science of the University of Virginia. But besides this he has been unstinting in good advice to many departments, large and small, that have known of his capability and experience and have wanted his help in building themselves up.

So, today, the Association extends to Bill Duren its recognition of his services, past and present, confident that by his very nature, those distinguished services are not about to stop.

E. J. McSHANE

AWARD OF THE 1967 CHAUVENET PRIZE TO PROFESSOR GUIDO L. WEISS

The Board of Governors of the Mathematical Association of America voted to award the 1967 Chauvenet Prize to Professor Guido L. Weiss of Washington University for his paper "Harmonic Analysis," published in *MAA Studies in Mathematics*, Volume 3 (1965) 124–178.

A certificate and monetary award in the amount of five hundred dollars was presented to Professor Weiss at the time of the Business Meeting of the Association on January 27, 1967, at Houston.

The Chauvenet Prize is awarded for a noteworthy expository paper published in English, such as will come within the range of profitable reading for members of the Association. The purpose of the prize is to stimulate the writing of expository works by American scholars. The 1967 Prize, awarded for a paper published in 1965 by a member of the Association, is the sixteenth award of the Chauvenet Prize since its institution by the MAA in 1925. For a list of the names of the previous winners, see this MONTHLY, 71 (1964), page 589 and 72 (1965), pp. 2–3.

Professor Weiss was born on December 29, 1928, in Trieste, Italy. He received his Ph.B. degree in 1949, his M.S. in 1951, and his Ph.D. in 1956, all from the University of Chicago. During 1953 and part of 1954, he was employed as a mathematician in the Advisory Board on Simulation (a project at the University of Chicago). In 1955, Professor Weiss was appointed as an instructor at De Paul University; he was promoted to Assistant Professor in 1956 and to Associate Professor in 1959. From May to September 1960 he was a Visiting Professor at the University of Buenos Aires. During 1960–61, he spent a year as National Science Foundation Postdoctoral Fellow at the Institute Poincaré at the Sorbonne. In 1961, he was appointed Associate Professor at Washington University and was promoted to Professor in 1963. He spent the Summer Quarter of 1963 as Visiting Professor at the University of Chicago. During the 1964–65 academic year, he was associated as Senior Postdoctoral National Science Foundation Fellow with the University of Geneva.

Professor Weiss' many substantial contributions in the field of analysis, and specifically to the theory of harmonic functions and harmonic analysis, are contained in his numerous papers which have appeared in both domestic and foreign publications.

In accepting the 1967 Chauvenet Prize, Professor Weiss expressed his strong feeling that the writing of expository papers should be encouraged and that, for this reason, he was very happy to write the chapter on "Harmonic Analysis" in *MAA Studies in Mathematics*. He found it most encouraging that, while never expecting this, he had received such a high honor for writing this article.

STARLIKE GRAPHS

GARY CHARTRAND, Western Michigan University and
S. F. KAPOOR, Michigan State University

1. Introduction. A connected ordinary graph $G(V, X)$ with vertex set V and edge set X will be called *starlike at a vertex* $p \in V$ (or simply *starlike*) provided (i) there exists a spanning tree $T(V, Y)$ in G which is homeomorphic to a star graph S, with deg p equal to the number of edges in S and (ii) for all $a \in V$, the distance from p to a is the same in T as in G. Such a point p will be called a *center*.

Examples of starlike graphs include (see Fig. 1 where the dotted lines indicate the edges in T) star graphs, complete graphs, paths, cycles and complete bipartite graphs. (For definitions of basic terms see [2] and [3].)

The principal result of this paper is a characterization of starlike graphs. Several results concerning the structure of such graphs are discussed.

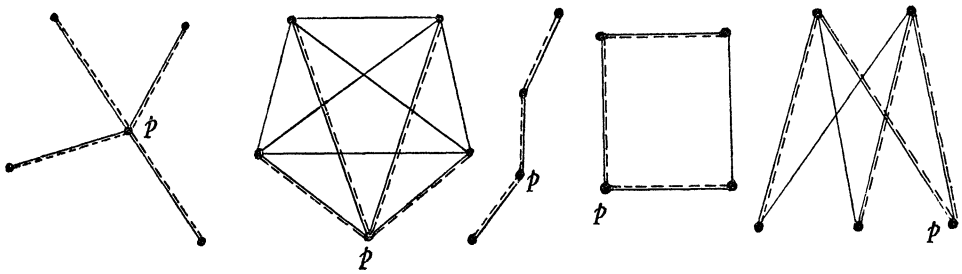

FIG. 1

2. Basic terminology. Let G be an *ordinary graph*, i.e. finite, undirected, and without loops or multiple edges. It is well known that if the *distance* $d(u, v)$ between two vertices u and v of a connected ordinary graph $G(V, X)$ is defined to be zero if $u = v$ and as the length of a shortest path joining u and v if $u \neq v$, then the vertex set V of G is a metric space with this distance function.

A *tree* is a connected graph without cycles. A *spanning tree* in a connected graph G is a tree which contains all the vertices of G. A *star graph* S is a tree having a point p adjacent to all the other points of S.

A graph G with vertex set V is said to be *isomorphic* to a graph G' with vertex set V' if there exists a one-to-one correspondence between V and V' such that two vertices are adjacent in G if and only if the corresponding vertices in G' are adjacent. Two graphs G and G' are said to be *homeomorphic* if it is possible to insert new vertices of degree 2 into their edges in such a way that the resulting graphs are isomorphic.

A vertex v of a graph G is a *cut point* if the removal of v (and all edges incident with v) from G results in a subgraph G' having more components than G.

In particular, the removal of a cut point from a connected graph results in a disconnected graph. A *block* of a graph is a maximal connected subgraph which contains no cut points of itself. A block will be called *trivial* if it contains exactly one edge, and otherwise it will be called *nontrivial*. A cut point p is called *k-block* if it belongs to k nontrivial blocks. In particular for $k=0$, p is called *trivial*; for $k=1$, p is called *mono-block* and for $k\geqq 2$, p is called *poly-block*. The number of blocks to which a vertex v belongs is called the *connective index* of v and is denoted by $i(v)$. It follows immediately that v is a cut point of G if and only if $i(v)\geqq 2$ and if v is a k-block cut point, then $i(v)\geqq k$.

For each point a of a graph $G(V, X)$ and for each $i=0, 1, 2, \cdots$, we define $A_i(a)=\{v\in V \mid d(a, v)=i\}$. For example, $A_0(a)=\{a\}$ and $A_1(a)$ consists of all those vertices adjacent to a. Consider the (multiple-valued) function f defined on $A_{i-1}(a)$, $i\geqq 1$, by

$$f(u) = \{v \in A_i(a) \mid (u, v) \in X\}.$$

Hence, for $w\in A_i(a)$, $i\geqq 1$,

$$f^{-1}(w) = \{u \in A_{i-1}(a) \mid (u, w) \in X\}.$$

Then if W is a nonempty subset of $A_i(a)$,

$$f^{-1}(W) = \{f^{-1}(w) \mid w \in W\}.$$

A set $Z\subseteq X$ in a graph $G(V, X)$ is called *independent* if no two elements of Z have a vertex in common. If V_1 and V_2 are nonempty disjoint subsets of V then V_1 is said to be *matched into* V_2 if there exists an independent set $Z\subseteq X$ which joins all elements of V_1 with elements of V_2. For $v_1\in V_1$ and $W\subseteq V_1$ define

$$g(v_1) = \{v_2 \in V_2 \mid (v_1, v_2) \in X\}$$

and

$$g(W) = \{g(w) \mid w \in W\}.$$

3. A characterization of starlike graphs. The following theorem (see [1], p. 92) gives a necessary and sufficient condition under which V_1 can be matched into V_2.

THEOREM (D. KÖNIG AND P. HALL). *V_1 can be matched into V_2 if and only if for all $W\subseteq V_1$, $|g(W)|\geqq|W|$.*

($|C|$ denotes the cardinal number of the set C.)

THEOREM 1. *A connected graph $G(V, X)$ is starlike if and only if there exists a point $p\in V$ such that for every nonempty subset W of $A_i(p)$, $i\geqq 2$, $|f^{-1}(W)|\geqq|W|$.*

Proof. Suppose $G(V, X)$ is starlike with a spanning tree T and center p as defined above. Let $W=\{w_1, w_2, \cdots, w_k\}$ be a nonempty subset of $A_i(p)$, $i\geqq 2$. For each $w_j\in W$, $j=1, 2, \cdots, k$, let u_j be the vertex in $A_{i-1}(p)$ which lies on

the path in T from p to w_j. Then $u_j \in f^{-1}(w_j)$ so that $\{u_1, u_2, \cdots, u_k\} \subseteq f^{-1}(W)$. This implies that $|f^{-1}(W)| \geqq |W|$.

Conversely, suppose there exists a point p such that if W is any nonempty subset of $A_i(p)$, $i \geqq 2$, then $|f^{-1}(W)| \geqq |W|$. We show that $G(V, X)$ is starlike at p by defining a spanning tree $T(V, Y)$ with the desired properties.

Consider the bipartite subgraphs B_i of $G(V, X)$, $i \geqq 2$, where the vertex set of B_i is $A_{i-1}(p) \cup A_i(p)$ and whose edge set X_i consists of all elements of X which join a vertex of $A_i(p)$ with a vertex of $A_{i-1}(p)$.

With $A_i(p)$ and $A_{i-1}(p)$ playing the roles of V_1 and V_2, respectively, we note that for $W \subseteq A_i(p)$, $f^{-1}(W) = g(W)$. Hence the theorem of König and Hall applies to give a matching of $A_i(p)$ into $A_{i-1}(p)$, $i \geqq 2$. This produces an independent set $Y_i \subseteq X_i$ such that $|Y_i| = |A_i(p)|$. Defining Y_1 to be the set of all edges incident with p, we clearly have the desired tree $T(V, \bigcup Y_i)$, (see Fig. 2).

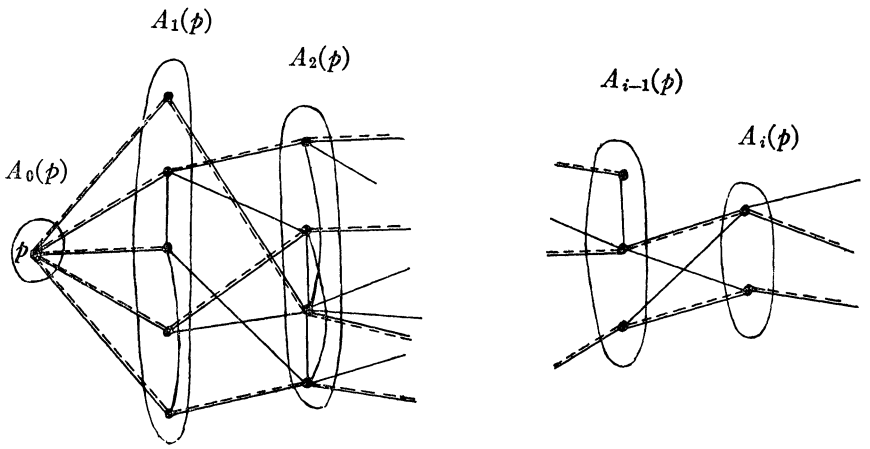

FIG. 2

4. Some properties of starlike graphs.

THEOREM 2. *Let $G(V, X)$ be a connected graph for which $|V| = n$. If there exists a vertex $p \in V$ with* deg $p \geqq n-2$, *then G is starlike and p is a center.*

Proof. Since deg $p \geqq n-2$, $A_1(p) = \{a_1, a_2, \cdots, a_k\}$, where $k = n-1$ or $n-2$. We define a spanning tree $T(V, Y)$ for each of the two cases as follows. For $k = n-1$, let $Y = \{(p, a_j) | j = 1, 2, \cdots, n-1\}$.

If $k = n-2$, then there exist vertices a' and b with $a' \in A_1(p)$ and $A_2(p) = \{b\}$ such that $(a', b) \in X$. In this case, take $Y = \{(p, a_j) | j = 1, 2, \cdots, n-2\} \cup \{(a', b)\}$. Hence, G is starlike and p is a center.

THEOREM 3. *Every block of a starlike graph is starlike.*

Proof. Let $G(V, X)$ be a graph which is starlike at p, and let $T(V, Y)$ be a corresponding spanning tree in G. If B is a block of G, and p is in B, then B is

starlike at p since we can take as the edge set for an appropriate spanning tree T' of B all those edges belonging to both B and T. If $p \notin B$, then there exists a smallest value r of i for which a point $p' \in B \cap A_i(p)$. Clearly, p' is a cut point of G, and no other point of B belongs to $A_r(p)$. B is starlike at p', and we take for the edge set of an appropriate spanning tree T' of B those edges belonging to $B \cap T$.

The converse of the preceding theorem does not follow as can be seen by the graph given in Figure 3.

FIG. 3

THEOREM 4. *If a starlike graph G contains a nontrivial block B, then any center of G belongs to B.*

Proof. If G is starlike at p and $p \notin B$, then there is a minimum value r of i (where $r \geqq 1$) such that a point v of B belongs to $A_i(p)$. As in the proof of Theorem 3, v is a cut point of G, and no other vertex of B belongs to $A_r(p)$. Since B is nontrivial there are at least two vertices w_1 and w_2 in B adjacent to v. Clearly, $\{w_1, w_2\} \subseteq A_{r+1}(p)$. If we let $W = \{w_1, w_2\}$, then $f^{-1}(W) = \{v\}$, which contradicts Theorem 1; hence, $p \in B$.

COROLLARY. *If a graph G containing only one poly-block cut point p is starlike, then p is the unique center of G.*

Proof. Since p is a poly-block cut point, G contains at least two nontrivial blocks. But by Theorem 4, any center must belong to all these nontrivial blocks and p is the only point with this property.

REMARK. From the preceding theorem and corollary, it then follows that starlike graphs have at most one poly-block cut point.

THEOREM 5. *If a starlike graph G has a vertex p with $i(p) \geqq 3$, then p is the unique center of G.*

Proof. Suppose G is starlike at v and $v \neq p$. If $d(v, p) = r$, then $p \in A_r(v)$. Any path from v to p contains points of only one block to which p belongs; hence, the distance from v to points in the other (two or more) blocks to which p belongs exceeds r. In particular, there are at least two points w_1 and w_2 (one in each of two such blocks) which are adjacent to p such that $w_1 \in A_{r+1}(v)$ and $w_2 \in A_{r+1}(v)$. Now if $W = \{w_1, w_2\}$, we see that $f^{-1}(W) = \{p\}$, and this contradicts Theorem 1. Thus, G is starlike at p.

COROLLARY. *A tree is starlike if and only if it has at most one vertex of degree three or more.*

Proof. If a tree has no vertex of degree three or more, it is a path and is starlike. On the other hand, if it has precisely one vertex of degree three or more, then it is homeomorphic to a star graph and is starlike.

If a tree T has two vertices of degree three or more, then since $i(v) = \deg v$ in a tree, T cannot be starlike, for otherwise Theorem 5 gives an immediate contradiction.

It therefore follows that if a starlike tree has more than one center, it is a path.

5. Summary. In a connected graph G, let

$c =$ the number of nontrivial blocks,
$\tau =$ the number of vertices of degree three or more, and
$N =$ the intersection of all the nontrivial blocks of G.

Then,

(a) G is starlike if $c = 0$ and $\tau \leqq 1$.
(b) G is not starlike if $c = 0$ and $\tau \geqq 2$ or $c \geqq 2$ and $N = \phi$.
(c) G may be starlike at p if $c \geqq 2$ and $N = \{p\}$.
(d) If $c = 1$, any center of G must lie in the nontrivial block if the graph is starlike.

The authors are most grateful to Professor E. A. Nordhaus for his suggestions and comments.

A PROBLEM ON RANDOM POINTS IN A TRIANGLE

ULRICH KRENGEL, University of California, Berkeley

1. Problem. Let $\triangle$ be the triangle in R^2, which is determined by the points (0, 0), (2, 0), and (1, 1). We denote the Lebesgue measure in the plane by m. Clearly $m(\triangle) = 1$. We say that n points $A_1, \cdots, A_n$ are chosen (independently) at random in $\triangle$, if their coordinates (x_i, y_i) are determined at random in such a way that for any n measurable subsets $D_1, \cdots, D_n$ of $\triangle$ the probability $P(A_1 \in D_1, \cdots, A_n \in D_n)$ is $m(D_1) \cdots m(D_n)$.

Now call $(x, y) \in \triangle$ *covered* if for some k the inequalities $|x - x_k| < y - y_k$ and $y - y_k > 0$ are both satisfied. Call A_i a *corner-point* if it is not covered. Let

N_n be the number of corner-points. We calculate the expectation of this random variable and derive recursion-formulas for the variance and for the exact distribution, which allow easy calculations. A closed expression for the variance and for the distribution has not been obtained.

We further discuss some related problems, which are of interest for the applications, and derive results in the much easier case in which $\triangle$ is replaced by the unit-square. This case corresponds to a combinatorial problem.

2. Application. The described problem is a variant of a question suggested by crystallographic investigations. A wire of length l is exposed to such conditions that at random locations and random times crystals are born along the wire. These are small points at their birth but grow with constant speed u on both sides. When they touch their neighbour the growth stops on the side where contact is made. New crystals can be born only on uncovered wire. What will be the expected number of crystals when the wire is covered or after time t? To simplify this question we assume that at time $t=0$ there are already two crystals at the endpoints of the wire. This may be assumed if the wire carries crystals already and a specified uncovered piece between two crystals is observed.

In the case $u=0$ one obtains a two-dimensional Poisson-distribution, the coordinates being location and time. In the case $u>0$ the set of possible birth-points is an isosceles triangle. Normalizing the time-scale we may assume it to be rectangular.

The reduction to the problem on random points is done as follows: we imagine that the crystals don't grow except for the two at the ends of the wire. Then we obtain random-points in a triangle. The number R of random-points is Poisson-distributed:

$$\text{Prob}\{R = n\} = e^{-\lambda}\frac{\lambda^n}{n!} \tag{1}$$

(Computation of λ: For a wire of length l the limit

$$\gamma = \lim_{t\to 0}\frac{1}{tl} \times \text{Prob}\{\text{at least one crystal until time } t\}$$

exists and is an empirical constant which measures the tendency to form crystals. $\lambda=\gamma l^2/4u$.)

If the crystals grow, the distribution is essentially the same except that some of the n crystals do not come into being; these are the "covered" random points. Hence, if N_∞ is the number of crystals born,

$$\text{Prob}(N_\infty = k) = \sum_{n=0}^{\infty} e^{-\lambda}\frac{\lambda^n}{n!}\,\text{Prob}\,(N_n = k). \tag{2}$$

This reduces as well the problem of calculating the expectation and variance

of N_∞ to the corresponding problem for N_n. In practice λ is small, so that the series converges rapidly and the distribution of N_n is needed only for small n.

3. Expectation. We first calculate the expectation of N_n and of N_∞.

THEOREM 1. *The expected number of corner-points out of n random points in* $\triangle$ *is given by*

$$E_n = E(N_n) = \frac{(2^n n!)^2}{(2n)!} - 1. \tag{3}$$

Proof. Let $A_i = (x_i, y_i)$, $i = 1, \cdots, n$ be the random points. A_n is a corner-point if and only if the triangle between (x_n, y_n), $(x_n - y_n, 0)$, and $(x_n + y_n, 0)$ contains none of the points $A_1, \cdots, A_{n-1}$. Its area is y_n^2; hence this has probability $(1-y_n^2)^{n-1}$. Integrating this in $\triangle$, we find the probability that A_n is a corner-point to be

$$\int_0^1 (1 - y_n^2)^{n-1}(2 - 2y_n)dy_n. \tag{4}$$

But the points being chosen independently, this probability is the same for all A_i so that we find the expectation of N_n to be

$$E_n = 2n \int_0^1 (1 - z^2)^{n-1}(1 - z)dz. \tag{5}$$

The evaluation of (5) yields (3).

If one counts only the corner-points with y-coordinates smaller or equal to $s \leqq 1$, the integral in (4) runs from 0 to s. Now assuming the number n Poisson-distributed as in (1), the expectation of the number of corner-points (x_k, y_k) with $y_k \leqq s$ is

$$\begin{aligned} \sum_{n=1}^{\infty} e^{-\lambda} \frac{\lambda^n}{n!} 2n \int_0^s (1 - z^2)^{n-1}(1 - z)dz &= \exp(-\lambda)2\lambda \int_0^s \exp(\lambda(1 - z^2))(1 - z)dz \\ &= (4\lambda\pi)^{1/2}\{\Phi(s(2\lambda)^{1/2}) - \tfrac{1}{2}\} \\ &\quad + \exp(-\lambda s^2) - 1, \end{aligned} \tag{6}$$

where $\Phi(x)$ is the normalized normal distribution. For $s = 2ut/l \leqq 1$ this is the expected number of crystals formed up until time $t \leqq l/2u$. Especially this proves:

THEOREM 2. *If* N_∞ *is the number of corner-points among Poisson-distributed random points,* $E(N_\infty)$ *is given by* (6) *with* $s = 1$.

This method of derivation may be applied in the case that there are no crystals at the endpoints of the wire in the beginning, but the integrals in that case get far more complicated and must be split into many parts.

4. Recursion formulas. For the derivation of recursion formulas for the distribution of N_n and its variance choose independently n points in $\triangle$ and let (x_0, y_0) be the point with the smallest y-coordinate. It is unique with probability 1. $\Delta' = \triangle \cap \{y \geqq y_0\}$ splits into a covered rectangle of area say F_1 and two uncovered triangles of area F_2 and F_3. The ratios $F_1 : F_2 : F_3$ determine the joint distribution of the numbers h, i, j of points in F_1, F_2, and F_3. Without loss of generality, assume $y_0 = 0$. We obtain $F_1 = x_0(2 - x_0)/2$, $F_2 = x_0^2/4$ and $F_3 = (2-x_0)^2/4$. Put $\text{Prob}\{N_n = k\} = P_{nk}$. $N_n = k$ holds if and only if for some k_2 and k_3 with $k_2 + k_3 = k-1$ there are k_2 corner-points in F_2 and k_3 corner-points in F_3. Using the multinomial distribution for $n-1$ points and integrating over all possible values of x_0 with uniform density $1/2$, we obtain

$$P_{nk} = \frac{1}{2}\int_0^2 \sum_{h+i+j=n-1} \frac{(n-1)!}{h!i!j!} F_1^h F_2^i F_3^j \sum_{k_2+k_3=k-1} P_{ik_2} P_{jk_3} dx_0. \tag{7}$$

First we calculate the integral

$$\int_0^2 F_1^h F_2^i F_3^j dx_0 = 2^{h+1} \frac{(2i+h)!(2j+h)!}{(2h+2i+2j+1)!}.$$

We introduce the generating functions $P_n(s) = \sum_{k=0}^{\infty} P_{nk} s^k$. Clearly $P_0(s) = 1$. For $n \geqq 0$ replacing n by $n+1$ in (7) we get

$$P_{n+1}(s) = \frac{s}{2} \sum_{h+i+j=n} P_i(s) P_j(s) \frac{n!}{h!i!j!} 2^{h+1} \frac{(2i+h)!(2j+h)!}{(2n+1)!}. \tag{8}$$

This is already the recursion for the probabilities, but (8) is simplified if we introduce $Q_{nk} = (2n)!(2^n n!)^{-1} P_{nk}$ and $Q_n(s) = (2n)!(2^n n!)^{-1} P_n(s)$. With these changes (8) is equivalent to

$$Q_{n+1}(s) = s \sum_{i+j=0}^{n} Q_i(s) Q_j(s) \frac{(n+i-j)!(n-i+j)!}{(2i)!(2j)!(n-i-j)!}. \tag{9}$$

Computation starts from $Q_0(s) = 1$. The coefficients

$$c(n, i, j) = (n+i-j)!(n-i+j)!((2i)!(2j)!(n-i-j)!)^{-1}$$

turn out to be integers.

Here are the first few polynomials $Q_k(s)$: $Q_0(s) = 1$, $Q_1(s) = s$, $Q_2(s) = s + 2s^2$, $Q_3(s) = 2s + 8s^2 + 5s^3$, $Q_4(s) = 6s + 38s^2 + 47s^3 + 14s^4$, $Q_5(s) = 24s + 220s^2 + 415s^3 + 244s^4 + 42s^5$. Let us state the result:

THEOREM 3. *The generating functions* $Q_n(s)$ *of* $Q_{nk} = (2n)!(2^n n!)^{-1} \text{Prob}\{N_n = k\}$ *are recursively determined by* $Q_0(1) = 1$ *and* (9).

We now start to derive a recursion formula for the variances by taking derivatives in (9). For short we write $Q_n = Q_n(1)$, $Q_n' = Q_n'(1)$ and $Q_n'' = Q_n''(1)$. We obtain the equations:

$$Q'_{n+1} = Q_{n+1} + 2\sum_{k+j=0}^{n} Q'_k Q_j c(n, k, j) \tag{10}$$

and

$$Q''_{n+1} = 4\sum_{k+j=0}^{n} Q'_k Q_j c(n, k, j) + 2\sum_{k+j=0}^{n} Q''_k Q_j c(n, k, j) + 2\sum_{k+j=0}^{n} Q'_k Q'_j c(n, k, j). \tag{11}$$

Clearly $Q_n = (2n)!(2^n n!)^{-1}$ and $Q'_n = Q_n E_n = 2^n n! - Q_n$ by Theorem 1. Together with (10) this implies the identity

$$\begin{aligned} 2^{n+1}(n+1)! = Q'_{n+1} + Q_{n+1} &= 2\sum_{k+j=0}^{n} (Q'_k + Q_k) Q_j c(n, k, j) \\ &= 2\sum_{k+j=0}^{n} 2^k k! Q_j c(n, k, j). \end{aligned} \tag{12}$$

These equations now allow us to simplify (11) to

$$Q''_{n+1} = \sum_{k+j=0}^{n} Q''_k Q_j c(n, k, j) + 2\sum_{k+j=0}^{n} 2^k k! 2^j j! c(n, k, j) - 2Q_{n+1}. \tag{13}$$

We put $V_n = \mathrm{Var}(N_n)$. From $V_n = P_n'' + P_n' - P_n'^2$ and using Theorem 1 it is shown that

$$(2n)!(2^n n!)^{-1} V_n = Q_n'' - 2Q_n + 3(2^n n!) - (2^n n!)^3((2n)!)^{-1}.$$

With $W_n = Q_n'' - 2Q_n + 3(2^n n!)$ from (12) and (13) the formula

$$W_{n+1} = 2\sum_{k+j=0}^{n} (W_k Q_j + 2^{k+j} k! j!) c(n, k, j) \tag{14}$$

is obtained by straight-forward computation. We have proved the

THEOREM 4. *$V_n = \mathrm{Var}(N_n)$ may be calculated from*

$$V_n = 2^n n!((2n)!)^{-1} W_n - (2^n n!)^4((2n)!)^{-2},$$

where $W_0 = 1$ and W_n is recursively determined by (14).

REMARK. We mention that an explicit expression for P_{nk} and $P_{\infty k} = \mathrm{Prob}\{N_\infty = k\}$ may be derived as an iterated integral. Take (0, 0), ($\sqrt{2}$, 0) and ($\sqrt{2}$,$\sqrt{2}$) as corners of $\triangle$. Then a point (x, y) will be called covered if for some k both of the inequalities $x > x_k$, $y < y_k$ are satisfied. P_{nk} is $(n)_k$ times the probability that just $A_1, \cdots, A_k$ are corner-points and $x_1 < \cdots < x_k$ holds. Given $A_1, \cdots, A_k$ the points $A_{k+1}, \cdots, A_n$ must lie in the "covered" domain which has area $F_{(k)} = \sum_{j=1}^{k} (\sqrt{2} - x_j)(y_j - y_{j-1})$ with $y_0 = 0$. We obtain for $n \geqq 1$ and $1 \leqq k \leqq n$:

$$P_{nk} = (n)_k \int_0^{\sqrt{2}} dx_1 \int_0^{x_1} dy_1 \int_{x_1}^{\sqrt{2}} dx_2 \int_{y_1}^{x_2} dy_2 \cdots \int_{x_{k-1}}^{\sqrt{2}} dx_k \int_{y_{k-1}}^{x_k} dy_k F_{(k)}^{n-k}.$$

Formula (2) now implies:

$$P_{\infty k} = e^{-\lambda}\lambda^k \int_0^{\sqrt{2}} dx_1 \int_0^{x_1} dy_1 \cdots \int_{x_{k-1}}^{\sqrt{2}} dx_k \int_{y_{k-1}}^{x_k} dy_k e^{\lambda F(k)}.$$

The second integration, however, already leads to nonelementary functions, so that the recursion-formulas seem to be more useful.

5. Ladder-points. A far more natural mathematical question arises if we replace the triangle $\triangle$ by the unit-square, which shall be noted by $\triangle^*$. Here again covered points shall be defined as in the remark after Theorem 4. For this problem we use the same notation adding a star * to every symbol. In this case the P_{nk}^* remain unchanged if the uniform distributions of the x- and y-coordinates are replaced by any two continuous distributions F_x and F_y as long as all coordinates x_i, y_j are chosen independently.

In fact the problem for $\triangle^*$ is a combinatorial one rather than one of geometric probability. Given a sequence $n_1, n_2, \cdots$, of real numbers, call (k, n_k) a *ladder-point* if $n_k > n_i$ holds for all $i<k$ (analogous to the definition in the theory of random walk). P_{nk}^* is the probability of k ladder-points in a random-permutation $(n_1, \cdots, n_n)$ of the numbers $1, \cdots, n$ with all permutations equally probable.

THEOREM 5. *N_n^* is the sum of n independent random-variables $X_1, \cdots, X_n$ with* Prob $\{X_i=1\} = 1/i$ *and* Prob $\{X_i=0\} = (i-1)/i$. *Especially*:

$$E(N_n^*) = \sum_{i=1}^{n} 1/i \quad \textit{and} \quad \operatorname{Var}(N_n^*) = \sum_{i=1}^{n} (i-1)/i^2.$$

Proof. For $n=1$ the statement is obvious. Let it be true for n and consider permutations of $0, 1, \cdots, n$. These have the same distribution of ladder-points as those of $1, \cdots, n+1$. 0 yields a ladder-point if and only if it occurs at the first place, that is, with probability $1/n+1$, and the number of other ladder-points is not changed by putting 0 at any place.

THEOREM 6. *The exact distribution P_{nk}^* of N_n^* for $n \geqq 1$ is given by*

$$P_{nk}^* = \sum_{1 \leqq i_1 < i_2 \cdots < i_k = n} (i_1 \cdots i_k)^{-1}. \tag{15}$$

It satisfies the recursion formula

$$P_{nk}^* = (1/n) \sum_{m=0}^{n-1} P_{m(k-1)}^*. \tag{16}$$

Proof. From Theorem 5 it follows that P_{nk}^* is the sum of all terms $(n!)^{-1}(j_1-1) \cdots (j_{n-k}-1)$ with $1 \leqq j_1 < \cdots < j_{n-k} \leqq n$. This is equivalent to (15). To prove (16) observe that n yields a ladder-point wherever it occurs in the permutation $(n_1, \cdots, n_n)$. For every j the probability that $n_j = n$ is $1/n$, and if $n_j = n$ the

other $k-1$ ladder-points must occur among the first $m=j-1$ places. There m different numbers are ordered at random which may be given the new names $1', \cdots, m'$ in an order-preserving way.

The exact distribution as well could be derived from the recursion formula by induction. Calculation of P^*_{nk} is done faster using the recursion formula than using the explicit expression.

This work was prepared with partial support of the National Science Foundation, GP-2593.

Acknowledgment. I wish to thank Dr. H. Klinger for bringing the problem, as described in the beginning of Section 2, to my attention. Dr. Klinger (jointly with the author) was the first to obtain the expectation of the number of crystals born up until some time t by heavy use of integral-equations, Laplace transforms, etc. I also thank Professors J. Karush, M. Loève, P. K. Sen and W. Whitman for their interest and remarks, and especially Professor P. A. Moran for pointing out to us the related paper of J. L. Meijering: Interface area, edge length, and number of vertices in crystal aggregates with random nucleation; Philips Res. Rep. 8, 270–290, 1953. Meijering, among other questions in higher dimensions, considers a wire of infinite length and derives the distribution of the *length* of the crystals. Infinite length of the wire is a natural assumption if λ is large.

FUNCTIONS ON SEMI-SIMPLE ALGEBRAS

C. G. CULLEN, University of Pittsburgh, and C. A. HALL, Westinghouse Electric Corp., Bettis Atomic Laboratory

1. Introduction. Let $\mathfrak{A}$ be a finite dimensional linear associative algebra over the field $\mathfrak{F}$. We will consider only the case where $\mathfrak{A}$ is semi-simple (zero radical) over the real field R or the complex field C. It is known that

$$\mathfrak{A} = \mathfrak{A}_1 \oplus \mathfrak{A}_2 \oplus \cdots \oplus \mathfrak{A}_k$$

where the $\mathfrak{A}_i$ are simple algebras over $\mathfrak{F}$ [1].

Let F be a function from a domain $\mathfrak{D} \subseteq \mathfrak{A}$ to $\mathfrak{A}$. For each $\alpha \in \mathfrak{D}$ we have unique α_i and β_i in $\mathfrak{A}_i$, $i=1, 2, \cdots, k$, such that

$$\alpha = \alpha_1 + \alpha_2 + \cdots + \alpha_k \quad \text{and} \quad F(\alpha) = \beta_1 + \beta_2 + \cdots + \beta_k.$$

If F is Hausdorff-differentiable then F_i, the restriction of F to $\mathfrak{A}_i$, satisfies

$$F_i(\alpha_i) = \beta_i, \qquad i = 1, 2, \cdots, k[7].$$

In general F_i need not map $\mathfrak{A}_i$ into $\mathfrak{A}_i$ and in fact the correspondence $\alpha_i \to \beta_i$ may not even define a function (single-valued) from $\mathfrak{A}_i$ to $\mathfrak{A}_i$.

If we start with functions F_i, from $\mathfrak{A}_i$ to $\mathfrak{A}_i$, then we can construct a function $F = F_1 \oplus F_2 \oplus \cdots \oplus F_k$ on $\mathfrak{A}$ by defining

$$F(\alpha) = F(\alpha_1 + \alpha_2 + \cdots + \alpha_k) = F_1(\alpha_1) + F_2(\alpha_2) + \cdots + F_k(\alpha_k).$$

The domain of F is $\mathfrak{D}=\mathfrak{D}_1\oplus\mathfrak{D}_2\oplus\cdots\oplus\mathfrak{D}_k$, where $\mathfrak{D}_i\subseteq\mathfrak{A}_i$ is the domain of F_i, and in this case F_i is clearly the restriction of F to $\mathfrak{A}_i$.

In this paper we will discuss how the nature of the F_i determines the nature of the function F.

2. Primary functions. In this section we will discuss functions on $\mathfrak{A}$ which are extensions of functions from C to C. Such functions are called primary functions and can be defined in several different, but essentially equivalent ways [3]. We choose the following definition of Sylvester and Buchheim.

DEFINITION 2.1. *Let f be a single valued function from C to C and let $\mathfrak{A}$ be an algebra over C. Consider $\alpha\in\mathfrak{A}$ with minimum polynomial $m(z)=\prod_{i=1}^{t}(z-\lambda_i)^{s_i}$ and assume that f is defined at each λ_i and analytic at λ_i if $s_i>1$. Now let $L_{f,m}(z)$ be the unique polynomial of degree less than the degree of $m(z)$ satisfying*

$$\left.\frac{d^jL_{f,m}(z)}{dz^j}\right|_{z=\lambda_i}=f^{(j)}(\lambda_i),\qquad \begin{matrix} j=0,1,\cdots,s_i-1,\\ i=1,2,\cdots,t.\end{matrix}$$

The function F, defined by $F(\alpha)=L_{f,m}(\alpha)$, is called the primary function with stem function f.

$L_{f,m}(z)$ is the Lagrange-Hermite interpolation polynomial and is given explicitly in [2] or [3].

The above definition can be applied to algebras over R by extending the ground field to C and computing $F(\alpha)$ as in Definition 1.1. If $F(\alpha)$ is an element of the original algebra then F is said to be defined at α with functional value $F(\alpha)$. A necessary and sufficient condition for this to occur is that $f(\bar{z})=\overline{f(z)}$ at the zeros of the minimum polynomial of α [5]. In this case it is known that $L_{f,m}(z)$ is a polynomial with real coefficients [2].

Suppose now that $\mathfrak{A}=\mathfrak{A}_1\oplus\mathfrak{A}_2\oplus\cdots\oplus\mathfrak{A}_k$ and that F_i is primary on $\mathfrak{D}_i\subseteq\mathfrak{A}_i$ with stem function $f, i=1, 2, \cdots, k$. If the minimum polynomial of $\alpha_i\in\mathfrak{A}_i$ is $m_i(z)$ then from Definition 2.1 we have

$$F_i(\alpha_i)=L_{f,m_i}(\alpha_i),\qquad i=1,2,\cdots,k.$$

We will show that the function F, from $\mathfrak{A}$ to $\mathfrak{A}$, defined by

$$F(\alpha)=F(\alpha_1+\alpha_2+\cdots+\alpha_k)=F_1(\alpha_1)+F_2(\alpha_2)+\cdots+F_k(\alpha_k)$$

is a primary function on $\mathfrak{A}$ with stem function f.

We first prove a preliminary result which is of interest in its own right. We show that the minimum polynomial, in Definition 2.1, may be replaced by any polynomial multiple of the minimum polynomial without changing the function on $\mathfrak{A}$ at all.

THEOREM 2.1. *Let F be a primary function on a domain $\mathfrak{D}\subseteq\mathfrak{A}$ with stem function f. Let $\alpha\in\mathfrak{D}$ have minimum polynomial $m(z)$ and let $p(z)$ be any polynomial divisible by $m(z)$. If f is defined at the roots of $p(z)$ and analytic at the repeated roots of $p(z)$ then $F(\alpha)=L_{f,m}(\alpha)=L_{f,p}(\alpha)$.*

Proof. Since $\mathfrak{A}$ is isomorphic to a subalgebra of a total matrix algebra it suffices to prove the theorem for $\alpha = A_1 \in C_n = \{n \times n \text{ matrices over } C\}$.

Let A_2 be a matrix such that the minimum polynomial of

$$A = \begin{bmatrix} A_1 & 0 \\ 0 & A_2 \end{bmatrix}$$

is $p(z)$ and let $F(A)$, $F(A_1)$ and $F(A_2)$ be the functional values computed using Georgi's definition of a matrix function which is known to be equivalent to Definition 2.1 [3]. Thus we have $F(A) = L_{f,p}(A)$ and $F(A_1) = L_{f,m}(A_1)$. Now we have, since

$$F(A) = \begin{bmatrix} F(A_1) & 0 \\ 0 & F(A_2) \end{bmatrix},$$

$$F(A) = L_{f,p}(A) = \begin{bmatrix} L_{f,p}(A_1) & 0 \\ 0 & L_{f,p}(A_2) \end{bmatrix} = \begin{bmatrix} F(A_1) & 0 \\ 0 & F(A_2) \end{bmatrix}$$

$$= \begin{bmatrix} L_{f,m}(A_1) & 0 \\ 0 & L_{f,p}(A_2) \end{bmatrix}$$

and it follows that $L_{f,p}(A_1) = L_{f,m}(A_1)$ as claimed.

THEOREM 2.2. *Let $\mathfrak{A} = \mathfrak{A}_1 \oplus \mathfrak{A}_2 \oplus \cdots \oplus \mathfrak{A}_k$ be semi-simple over $\mathfrak{F}$ with the $\mathfrak{A}_i$ as its simple direct summands. If F_i is the primary function on $\mathfrak{A}_i$ with stem function f, $i = 1, 2, \cdots, k$, then the function $F = F_1 \oplus F_2 \oplus \cdots \oplus F_k$ on $\mathfrak{A}$ defined by*

$$F(\alpha) = F(\alpha_1 + \alpha_2 + \cdots + \alpha_k) = F_1(\alpha_1) + F_2(\alpha_2) + \cdots + F_k(\alpha_k)$$

is the primary function on $\mathfrak{A}$ with stem function f.

Proof. Consider any $\alpha = \alpha_1 + \alpha_2 + \cdots + \alpha_k$ in the domain of F where $\alpha_i \in \mathfrak{A}_i$ has minimum polynomial $m_i(z)$. The minimum polynomial of α is then $m(z) = \text{l.c.m.}\{m_1(z), m_2(z), \cdots, m_k(z)\}$. Now from Definition 2.1 we have

$$F(\alpha) = F_1(\alpha_1) + F_2(\alpha_2) + \cdots + F_k(\alpha_k)$$

$$= L_{f,m_1}(\alpha_1) + L_{f,m_2}(\alpha_2) + \cdots + L_{f,m_k}(\alpha_k)$$

which by Theorem 2.1 reduces to $F(\alpha) = L_{f,m}(\alpha_1) + L_{f,m}(\alpha_2) + \cdots + L_{f,m}(\alpha_k)$ and by elementary properties of direct sums

$$F(\alpha) = L_{f,m}(\alpha_1 + \alpha_2 + \cdots + \alpha_k) = L_{f,m}(\alpha).$$

Thus F is the primary function on $\mathfrak{A}$ with stem function f.

The converse of Theorem 2.2 was proved in [6].

3. Intrinsic functions. In this section we discuss the intrinsic functions on $\mathfrak{A}$. The concept of an intrinsic function on $\mathfrak{A}$ was introduced in 1960 by Rinehart [4].

DEFINITION 3.1. *Let $\mathfrak{G}$ be the group of all automorphisms and anti-automorphisms of $\mathfrak{A}$ which leave $\mathfrak{F}$ element-wise invariant. A function F is said to be intrinsic on a domain $\mathfrak{D}\subseteq\mathfrak{A}$ if for every $\Omega\in\mathfrak{G}$ and for every $\alpha\in\mathfrak{D}$ we have $\Omega\alpha\in\mathfrak{D}$ and $F(\Omega\alpha)=\Omega F(\alpha)$.*

Every primary function on $\mathfrak{A}$ is known to be intrinsic but in general the class of intrinsic functions on $\mathfrak{A}$ is larger than the class of primary functions on $\mathfrak{A}$ [4, 2]. We will have need of a slightly less restrictive class of functions than those described in Definition 3.1.

DEFINITION 3.2. *Let $\mathfrak{A}=\mathfrak{A}_1\oplus\mathfrak{A}_2\oplus\cdots\oplus\mathfrak{A}_k$ be semi-simple with the $\mathfrak{A}_i$ as its simple direct summands and let $\mathfrak{H}$ be the subgroup of $\mathfrak{G}$ such that if $\Omega\in\mathfrak{H}$ then $\Omega\mathfrak{A}_i=\mathfrak{A}_i$, $i=1, 2, \cdots, k$. F is $\mathfrak{H}$-intrinsic if $F(\Omega\alpha)=\Omega F(\alpha)$ for all $\Omega\in\mathfrak{H}$.*

THEOREM 3.1. *Let $\mathfrak{A}=\mathfrak{A}_1\oplus\mathfrak{A}_2\oplus\cdots\oplus\mathfrak{A}_k$ be semi-simple with the $\mathfrak{A}_i$ as simple direct summands. Let F_i be a function on $\mathfrak{A}_i$, $i=1, 2, \cdots, k$, and define $F=F_1\oplus F_2\oplus\cdots\oplus F_k$ on $\mathfrak{A}$ by*

$$F(\alpha) = F(\alpha_1+\alpha_2+\cdots+\alpha_k) = F_1(\alpha_1)+F_2(\alpha_2)+\cdots+F_k(\alpha_k).$$

Then F is H-intrinsic on $\mathfrak{A}$ if and only if the F_i are intrinsic on the $\mathfrak{A}_i$.

Proof. Let F be $\mathfrak{H}$-intrinsic and consider Ω_i any automorphism or anti-automorphism of $\mathfrak{A}_i$. Let $\Omega\in\mathfrak{H}$ be such that its restriction to $\mathfrak{A}_i$ is Ω_i. (Consider $\alpha_j\in\mathfrak{A}_j$ where $j\neq i$. If Ω_i is an automorphism define $\Omega\alpha_j=\alpha_j$. If Ω_i is an anti-automorphism define $\Omega\alpha_j=\phi^{-1}(\phi(\alpha_j)^t)=\alpha_j'$ where ϕ is an isomorphism of $\mathfrak{A}_j$ into a matrix algebra.) Now, since F is intrinsic on $\mathfrak{A}$,

$$\begin{aligned}F(\Omega\alpha) &= F_1(\Omega\alpha_1)+F_2(\Omega\alpha_2)+\cdots+F_i(\Omega_i\alpha_i)+\cdots+F_k(\Omega\alpha_k) = \Omega F(\alpha)\\ &= \Omega F_1(\alpha_1)+\Omega F_2(\alpha_2)+\cdots+\Omega_i F_i(\alpha_i)+\cdots+\Omega F_k(\alpha_k)\end{aligned}$$

and since $\Omega\in\mathfrak{H}$ we have $F_j(\Omega\alpha_j)$, $\Omega F_j(\alpha_j)\in\mathfrak{A}_j$; $j=1, 2, \cdots, k$; so it follows, from the uniqueness of the $\mathfrak{A}_i$ component of $\Omega F(\alpha)=F(\Omega\alpha)$, that $F_i(\Omega_i\alpha_i)=\Omega_i F_i(\alpha_i)$ and hence that F_i is intrinsic on $\mathfrak{A}_i$.

Now suppose that each F_i is intrinsic and consider $\Omega\in\mathfrak{H}$. Since Ω, restricted to $\mathfrak{A}_i$, is an automorphism or anti-automorphism of $\mathfrak{A}_i$ it follows that

$$\begin{aligned}F(\Omega\alpha) &= F(\Omega\alpha_1+\Omega\alpha_2+\cdots+\Omega\alpha_k)\\ &= F_1(\Omega\alpha_1)+F_2(\Omega\alpha_2)+\cdots+F_k(\Omega\alpha_k)\\ &= \Omega F_1(\alpha_1)+\Omega F_2(\alpha_2)+\cdots+\Omega F_k(\alpha_k)\\ &= \Omega(F_1(\alpha_1)+F_2(\alpha_2)+\cdots+F_k(\alpha_k))\\ &= \Omega F(\alpha).\end{aligned}$$

Thus F is $\mathfrak{H}$-intrinsic as claimed, completing the proof.

It is well known [1] that the simple direct summands of $\mathfrak{A}$ are the minimal left ideals of $\mathfrak{A}$ and that they are unique up to isomorphism. For any $\Omega\in\mathfrak{G}$, $\Omega\mathfrak{A}_i$ is again a minimal left ideal of $\mathfrak{A}$ and hence is a direct summand of $\mathfrak{A}$. If

$\Omega\mathfrak{A}_i$ is isomorphic to $\mathfrak{A}_j (i \neq j)$ then we have $\dim(\mathfrak{A}_i) = \dim(\mathfrak{A}_j)$. If no pair of direct summands are isomorphic ($\dim(\mathfrak{A}_i) \neq \dim(\mathfrak{A}_j)$ for $i \neq j$) then, as a direct corollary of Theorem 3.1, we have

THEOREM 3.2. *Let $\mathfrak{A} = \mathfrak{A}_1 \oplus \mathfrak{A}_2 \oplus \cdots \oplus \mathfrak{A}_k$ be semi-simple with the $\mathfrak{A}_i$ as simple direct summands where $\mathfrak{A}_i$ is not isomorphic to $\mathfrak{A}_j$ if $i \neq j$. Let F_i be a function on $\mathfrak{A}_i$, $i = 1, 2, \cdots, k$, and define $F = F_1 \oplus F_2 \oplus \cdots \oplus F_k$ on $\mathfrak{A}$ by*

$$F(\alpha) = F(\alpha_1 + \alpha_2 + \cdots + \alpha_k) = F_1(\alpha_1) + F_2(\alpha_2) + \cdots + F_k(\alpha_k).$$

Under these conditions F is intrinsic on $\mathfrak{A}$ if and only if the F_i are intrinsic on the A_i.

We now give an example to show the necessity of the added hypothesis in Theorem 3.2. Let

$$\mathfrak{A} = R_2 \oplus R_2 = \left\{ \begin{bmatrix} A_1 & 0 \\ 0 & A_2 \end{bmatrix} \middle| A_1, A_2 \in R_2 \right\},$$

$R_2 = \{2 \times 2 \text{ matrices over } R\}$, and consider the functions $F_1(A_1) = A_1$ and $F_2(A_2) = A_2^2$ which are clearly intrinsic on the direct summands. It is easy to see that the mapping Ω, defined by

$$\Omega \begin{bmatrix} A_1 & 0 \\ 0 & A_2 \end{bmatrix} = \begin{bmatrix} A_2 & 0 \\ 0 & A_1 \end{bmatrix},$$

is an automorphism of $\mathfrak{A}$. Now for $F = F_1 \oplus F_2$ and $A = \operatorname{dg}\{2, 2, 3, 3\}$ we have

$$\Omega F(A) = \Omega F(\operatorname{dg}\{2, 2, 3, 3\}) = \Omega \operatorname{dg}\{2, 2, 9, 9\} = \operatorname{dg}\{9, 9, 2, 2\}$$

$$\text{while } F(\Omega A) = F(\operatorname{dg}\{3, 3, 2, 2\}) = \operatorname{dg}\{3, 3, 4, 4\} \neq \Omega F(A).$$

Thus $F = F_1 \oplus F_2$ is not intrinsic on $\mathfrak{A}$ even though F_1 and F_2 are intrinsic on the respective direct summands.

As the final result of this section we give conditions on the functions F_i which are necessary and sufficient for $F = F_1 \oplus F_2 \oplus \cdots \oplus F_k$ to be intrinsic on $\mathfrak{A}$.

THEOREM 3.3. *Let $\mathfrak{A} = \mathfrak{A}_1 \oplus \mathfrak{A}_2 \oplus \cdots \oplus \mathfrak{A}_k$ be semi-simple with the $\mathfrak{A}_i$ as simple direct summands. Let F_i be a function on $\mathfrak{A}_i$, $i = 1, 2, \cdots, k$, and define $F = F_1 \oplus F_2 \oplus \cdots \oplus F_k$ on $\mathfrak{A}$ by*

$$F(\alpha) = F(\alpha_1 + \alpha_2 + \cdots + \alpha_k) = F_1(\alpha_1) + F_2(\alpha_2) + \cdots + F_k(\alpha_k).$$

If there exists an automorphism or anti-automorphism Ω' of $\mathfrak{A}$ such that $\Omega'\mathfrak{A}_i = \mathfrak{A}_j (i \neq j)$, then require that $F_j(\Omega'\alpha_i) = \Omega' F_i(\alpha_i)$. Under these conditions F is intrinsic on $\mathfrak{A}$ if and only if the F_i are all intrinsic on the $\mathfrak{A}_i$.

Proof. If F is intrinsic then it is $\mathfrak{H}$-intrinsic and Theorem 3.1 assures us that the F_i are intrinsic.

Now let F_i be intrinsic on $\mathfrak{A}_i$, $i = 1, 2, \cdots, k$, and consider any automorphism or anti-automorphism Ω of $\mathfrak{A}$. Let ρ be the permutation on k-letters such

that $\Omega\mathfrak{A}_i=\mathfrak{A}_{\rho(i)}$, $i=1, 2, \cdots, k$. Our hypotheses yield

$$\Omega F_i(\alpha_i) = F_{\rho(i)}(\Omega\alpha_i) = F_{\rho(i)}((\Omega\alpha)_{\rho(i)}) \qquad \text{for } i = 1, 2, \cdots, k,$$

where $(\Omega\alpha)_{\rho(i)}$ is the unique $\mathfrak{A}_{\rho(i)}$ component of $\Omega\alpha$. Now for any $\alpha=\alpha_1+\alpha_2+\cdots+\alpha_k$ in $\mathfrak{A}$ we have

$$\Omega F(\alpha) = \Omega \sum_i F_i(\alpha_i) = \sum_i \Omega F_i(\alpha_i) = \sum_i F_{\rho(i)}((\Omega\alpha)_{\rho(i)}) = F(\Omega\alpha).$$

Thus F is intrinsic on $\mathfrak{A}$ as desired.

Presented to the Amer. Math. Soc., on January 24, 1966.

ONE MORE "MANY-MORE" ASSERTION

J. T. RYAN, Research Triangle Institute, Durham, N. C.

1. Introduction. Since 1859 mathematicians have spent thousands of hours counting prime numbers in their separate linear forms. Chebyshev suggested then that separate enumeration of the primes into the $4k+1$ and $4k+3$ arithmetic progressions might shed some light on the properties of these primes. His suggestion led Glaisher [1] actually to count by hand the number of such primes in the first hundred thousand numbers of the first through the ninth million numbers. This work by Glaisher was the first in a virtual parade of such efforts. From such counts as these and other mathematical results, a number of assertions have been made during the past 100 years about the relative numbers of integers in different arithmetic progressions. This paper describes the results of one of the latest of these counting efforts carried out by the author on a high speed digital computer. On the basis of the tallies obtained and some heuristic arguments by Shanks [2], a very general "many-more" assertion is made (Conjecture 3 below).

2. "Many-more" assertions. A "many-more" assertion is any statement (either of fact or of strong conjecture) that describes some sense in which one type of number occurs "more frequently" than another type in the sequence of positive integers. A theorem first proved by Phragmen [3], in 1891 and later, in a simpler way, by Landau, [4], [5], will provide a good example of such an assertion:

THEOREM 1. *Let $\pi_-(n)$ be the number of primes of the form $4k-1$ that are less than or equal to n. Similarly, let $\pi_+(n)$ be the number of primes of the form $4k+1$ that are less than or equal to n. If we let*

$$\Delta(n) = \pi_-(n) - \pi_+(n) \quad \text{and} \quad t(n) = \frac{\Delta(n)}{\sqrt{n}/\ln n} \tag{1, 2}$$

then (as Chebyshev, in fact, first conjectured but did not prove) for a certain subsequence, n_i, of the integers,

$$\lim_{i\to\infty} t(n_i) = 1. \tag{3}$$

Although this theorem certainly does not state that there are "many-more" primes of the form $4k-1$ than of the form $4k+1$, it shows a "sense" for which $4k-1$ primes predominate over $4k+1$ primes. (It is interesting to note that Glaisher incorrectly surmised the opposite from his early counts.)

Shanks provides us with a *quantitative statistical* interpretation of Chebyshev's "many-more" primes assertion. He suggests [2]:

CONJECTURE 1. If we let

$$\tau(n) = \frac{\Delta(n)\sqrt{n}}{\pi(n)}, \tag{4}$$

where $\pi(n)$ is the number of primes less than or equal to n, then the mean value of $\tau(n)$,

$$\bar{\tau}(n) = \frac{1}{n-1}\sum_{i=2}^{n} \tau(i) \tag{5}$$

has a limit as $n\to\infty$, and this limit equals $+1$; i.e.,

$$\lim_{n\to\infty} \bar{\tau}(n) = 1. \tag{6}$$

If this were true, we might say that in *an average sense* there are many more primes of the form $4m-1$ than of the form $4m+1$. More formally this can be stated: There exists an N such that $\bar{\tau}(n)>0$ for all $n>N$. Further, for any $\rho<1$, there exists an N such that $\bar{\tau}(n)>\rho$ for $n>N$.

Although Shanks presented some numerical evidence and heuristic arguments for Conjecture 1, he did not prove it. Nor is it likely to be proved or

disproved in the near future because of its known association with the famous Riemann Hypothesis about the zeros of the zeta function. In connection with his aforementioned heuristic arguments, Shanks was led to the following generalization of Conjecture 1:

CONJECTURE 2. Let a be a positive integer and let $\pi_{\pm}^{(a)}(n)$ be the number of positive integers of the form $4k \pm 1$ which are $\leqq n$ and which are the products of a (not necessarily distinct) primes; and further, let

$$\Delta^{(a)}(n) = \pi_{-}^{(a)}(n) - \pi_{+}^{(a)}(n), \tag{7}$$

$$\sum^{(a)}(n) = \pi_{-}^{(a)}(n) + \pi_{+}^{(a)}(n), \tag{8}$$

and

$$\tau^{(a)}(n) = \frac{\Delta^{(a)}(n)\sqrt{n}}{\sum^{(a)}(n)}. \tag{9}$$

Here we define $\tau^{(a)}(n) = 0$ if $\sum^{(a)}(n) = 0$. Then the average value:

$$\bar{\tau}^{(a)}(n) = \frac{1}{n}\sum_{k=1}^{n} \tau^{(a)}(k) \tag{10}$$

will tend to $(-1)^{a+1}$ in the limit as $n \to \infty$ for $a = 1, 2, 3, \cdots$.

This phenomenon will be called the "Shanks Flip-Flop Phenomenon." It is this conjecture and the heuristic arguments of Shanks that led the author to an even more general assertion regarding numbers in *any* arithmetic progression. This conjecture and the supporting evidence is presented in the next sections.

3. Another "many-more" assertion. Shanks' argument for the flip-flop behavior of the τ-function shown by Conjecture 2 was based on the assumption that the mean values of $\tau^{(1)}(x)$ (i.e., $\bar{\tau}^{(1)}(x) = 1/(x-1)\sum_{n=2}^{x} \tau(n)$) for $x = n^{1/a} (a = 2, 3, \cdots)$ are all equal to 1. This would imply that

$$\frac{\pi_{-}^{(1)}(x) - \pi_{+}^{(1)}(x)}{\pi_{-}^{(1)}(x) + \pi_{+}^{(1)}(x)}\sqrt{x} = 1 \tag{11}$$

in the mean, or that

$$\frac{\pi_{-}^{(1)}(x)}{\pi_{-}^{(1)}(x) + \pi^{(1)}(x)} = \frac{1}{\sqrt{x}} + \frac{\pi_{+}^{(1)}(x)}{\pi_{-}^{(1)}(x) + \pi^{(1)}(x)} = \frac{1}{\sqrt{x}} + 1 - \frac{\pi_{-}^{(1)}(x)}{\pi_{-}^{(1)}(x) + \pi_{+}^{(1)}(x)} \tag{12}$$

or simply

$$\frac{\pi_{-}^{(1)}(x)}{\pi_{-}^{(1)}(x) + \pi_{+}^{(1)}(x)} = \frac{1}{2}[x^{-1/2} + 1]. \tag{13}$$

It therefore follows that of all the odd primes of (geometric) mean order $n^{1/a}$, a fraction equal to $\frac{1}{2}(1+n^{-1/2a})$ is of the form $4m-1$ and similarly a fraction equal to $\frac{1}{2}(1-n^{-1/2a})$ is of the form $4m+1$. In this paper the order of an integer or group of integers is simply some number (usually an integer) which is "close to" the given integer or group of integers. That is, it is the approximate magnitude of the integer or group of integers. The geometric mean order of the prime factors of a number of order n and belonging to C^a is $n^{1/a}$ where C^a is the class of a-fold composite numbers.

We might now inquire as to whether this result or at least the Shank's Flip-Flop Phenomenon can be extended to the distribution of a-fold composites for any modulus.

The extension to the modulus 6 is simple because the multiplication table for primes of the form $6m-1$ and $6m+1$ is the same as for the modulus 4 primes:

	$6m+1$	$6m-1$
$6m+1$	$6m+1$	$6m-1$
$6m-1$	$6m-1$	$6m+1$

If the linear forms $4m-1$ and $4m+1$ are divided into the arithmetic progressions of modulus 8, we will have the four classes $8m+1$, $8m+3$, $8m+5$, and $8m+7$. We see that the classes $8m+1$ and $8m+5$ belong to the class of $4m+1$ forms. Landau's generalization of Chebyshev's assertion (for primes) to any modulus, [5, p. 704–711], suggests that the deficiency exhibited by the $4m+1$ primes will be confined entirely to $8m+1$. Shanks [2] provided numerical evidence to support this extension. He further showed that among the three remaining forms $8m+3$, $8m+5$, and $8m+7$, there are no significant differences in the "Chebyshev" sense.

The multiplication table modulo 10

1	3	7	9
3	9	1	7
7	1	9	3
9	7	3	1

provides us with two classes falling on the diagonal, the forms $10m+1$ and $10m+9$. These residue classes are the quadratic residues. Shanks also discussed the primes modulo 10. Here, evidence was shown which supports the conjecture

that the fluctuations in the $10m+3$ or $10m+7$ primes diminish the $10m+1$ primes. Extending his argument to numbers in C^a, we see that the residue classes 3 and 7 share the lead for odd-fold composites and the residue classes 1 and 9 share the lead for even-fold composites. In general, we might conjecture that the quadratic residue classes will always share the lead for even-fold composites, and that the quadratic nonresidue classes will always share the lead for odd-fold composites. Formally, this can be stated as

CONJECTURE 3. In the mean, among all C^a numbers of order n, a fraction equal to

$$\frac{1}{\Phi(m)}\left[1-(-1)^{a+1}(\Phi(m)-R(m))n^{-1/2}\right] \tag{14}$$

is of the form $mk+b$, where b is a quadratic residue of m, and a fraction equal to

$$\frac{1}{\Phi(m)}\left[1+(-1)^{a+1}R(m)n^{-1/2}\right] \tag{15}$$

is of the form $mk+c$, where c is a quadratic nonresidue of m and where $R(m)$ is the number of quadratic residues of m and $\Phi(m)$ is Euler's Function.

4. Some numerical evidence. Computer programs were written to provide data that might strengthen the case for Conjecture 3. Table I shows the average relative positions of the four modulo 8 linear forms. The numbers in this table were calculated in the following manner:

The position of each form was recorded at intervals of 100 up to 2,000,000. If a form was in the lead, it received a 1; if it was second, it received a 2, etc. If two forms shared a position, then the number of the position plus one-half was recorded for both forms and forms in all subsequent position would receive numbers accordingly, that is, as if there had been no ties. For example, if form A were in first place, forms B and C tied for second place, and form D in third place, form A would have a 1 recorded for it, forms B and C would have a $2\frac{1}{2}$ recorded for them, and form D would have a 4 recorded for it. These position values were then averaged over the stated values.

TABLE I

Average Relative Position of $\pi_{8,b}^{(a)}(n)$

a	$b=1$	3	5	7
1	4	2.02	1.97	2.01
2	1	3.03	2.99	2.98
3	4	1.96	1.98	2.06
4	1.01	2.96	3.07	2.96
5	3.99	2.00	2.02	1.99
6	1.01	3.14	2.95	2.90
7	3.94	2.02	2.04	2.00

Tables II and III provide similar data for the modulo 12 and modulo 10 linear forms.

TABLE II

Average Relative Position of $\pi_{12,b}^{(a)}(n)$

a	$b=1$	5	7	11
1	4	1.97	2.03	2.00
2	1.02	3.00	2.95	3.03
3	3.92	2.02	2.05	2.01
4	1.15	2.89	2.97	2.99
5	3.77	2.06	2.10	2.07
6	1.19	2.93	2.91	2.97
7	3.51	2.16	2.20	2.13

TABLE III

Average Relative Position of $\pi_{10,b}^{(a)}(n)$

a	$b=1$	3	7	9
1	3.51	1.51	1.48	3.50
2	1.51	3.53	3.47	1.49
3	3.48	1.46	1.55	3.51
4	1.57	3.49	3.45	1.49
5	3.54	1.43	1.51	3.52
6	1.53	3.52	3.50	1.45
7	3.50	1.54	1.47	3.49

MATHEMATICAL NOTES

A TOTIENT FUNCTION ON THE RESIDUE CLASSES MOD m AND OTHER SEMIGROUPS

ROBERT SPIRA, University of Tennessee

Is it possible to define an Euler totient function on an arbitrary commutative semigroup? In this paper we take up first the special case of defining such a ϕ-function on the semigroup of the integers mod m, and then study the conditions under which an analogously defined function would be multiplicative in an arbitrary commutative semigroup. The definition of the ϕ-function on the residue classes arose from trying to characterize the ordinary ϕ-function on the semigroup of rational integers using the residue classes themselves rather than by counting. This characterization was successful, as is shown by the corollary to Theorem 3. The point of view of using residue classes is the proper one, since for semigroups one would have to start with an assumed compatible residue partition, rather than a residue structure determined by an additive group.

We start with some definitions. Let the set of integers be partitioned into a set M of residue classes M_j.

$$M_j = \{n \mid n \equiv j \pmod m\} = \{n \mid n = sm + j,\ s = 0, \pm 1, \pm 2, \pm 3, \cdots\}$$
$$M = \{M_j \mid j = 1, \cdots, m\}.$$

DEFINITIONS:

(a) $(M_i, M_j) = 1$ *if and only if there is an* a *in* M_i *and a* b *in* M_j, *such that* $(a, b) = 1$,

(b) $\phi_m(j) =$ *the number of* M_i *such that* $(M_i, M_j) = 1$,

(c) $\phi(M) = \min_j \phi_m(j)$.

$\phi_m(j)$ is the totient function of the title, and is later shown to be multiplicative in m. We now start on a series of theorems giving the properties of $\phi_m(j)$. Hancock [1] also came upon some of these properties, starting from the idea of counting lattice points in a cube such that $(i, j, k) = 1$.

LEMMA. *If* $(a, b) = 1$ *and* n *is an integer, then there is an* x *such that* $(ax + b, n) = 1$.

Proof. While this lemma follows from Dirichlet's theorem, the following elementary proof can be given. x can be found $\leqq n$. Let $(a, n) = d$, $a = a_1 d$, $n = n_1 d$. Then $(a_1, n_1) = 1$. Let $n = N \cdot D$, where D contains all the primes dividing d to the highest possible power. Thus, $d \mid D$, $N \mid n_1$, $(N, d) = 1$. Also, since $(a_1, n_1) = 1$, $(a_1, N) = 1$, so $(a, N) = 1$. Thus, $ka + b (k = 1, \cdots, N)$ is a complete residue system mod N. Choose k so that $(ka + b, N) = 1$. Then $(ka + b, D) = 1$, for if p is a prime and $p \mid (ka + b, D)$, $p \mid d$. Hence, $p \mid a$, so $p \mid b$, but $(a, b) = 1$. Hence $(ka + b, n) = 1$.

THEOREM 1. $(M_i, M_j)=1$ *if and only if* $(m, i, j)=1$.

Proof. $(M_i, M_j)=1$ if and only if $(sm+i, tm+j)=1$ is solvable in integers s and t. Let $(m, i)=d_i$, $(m, j)=d_j$, $d=(d_i, d_j)$. If $d>1$, $d \mid sm+i$, $d \mid tm+j$, and we have $(sm+i, tm+j) \geqq d>1$ for all s and t, so $(M_i, M_j) \neq 1$. If $d=1$, using the lemma, choose s so that $s(m/d_i)+i/d_i=N_1$, $(N_1, d_j)=1$. Then choose t so that $t(m/d_j)+j/d_j=N_2$, $(N_2, N_1 d_i)=1$. Then $(sm+i, tm+j)=(d_i N_1, d_j N_2)=1$.

We remark that the definition of relative primality of M_i and M_j coincides with the notion derived from the theorem of unique factorization mod m (Vandiver and Weaver [2]). As shown there, each residue j is uniquely factorable (in a special sense), $j \equiv u p_1^{j_1} \cdots p_k^{j_k}$, where the p_i's are prime divisors of m and $(u, m)=1$. From our Theorem 1, it follows that $(M_i, M_j)=1$ if and only if $(m, i, j)=1$, and this is easily seen to be equivalent to i and j having no common primes also in common with m.

THEOREM 2. $\phi_m(m)=\phi(m)$.

Proof. In Theorem 1, set $j=m$, and count the number of times $(m, i, j)=(m, i, m)=(i, m)=1$. This number is clearly $\phi(m)$.

THEOREM 3. $\phi_m(j) \geqq \phi_m(m)$, *equality occurring only when* j *has all the prime factors of* m.

Proof. The case $m=1$ is clear. If $(j, m)=1$, $(i, j, m)=1$ for all i, so $(M_i, M_j)=1$ for all i so $\phi_m(j)=m>\phi(m)$ for $m>1$. Let now $(j, m)=d$, $1<d \leqq m$. Then $(i, j, m)=(i, d)$. Since $d \mid m$, $(m, i)=1$ implies $(d, i)=1$, so $\phi_m(j) \geqq \phi_m(m)$. If p is a prime dividing m, and $p \nmid j$, then $(p, j)=1$, so $\phi_m(j)>\phi_m(m)$. But if all primes dividing m divide j, then there are no more than $\phi(m)$ i's relatively prime to j, so Theorem 3 is proved.

COROLLARY. $\phi(M)=\phi(m)$.

THEOREM 4.

$$\phi_m(j) = m \frac{\phi((j, m))}{(j, m)}.$$

Proof. Let $(j, m)=d$. Then $(i, j, m)=(i, d)$, and $\phi_m(j)=$ the number of i's, $1 \leqq i \leqq m$, for which $(i, d)=1$. This is clearly $(m/d) \cdot \phi(d)$, and the theorem follows.

COROLLARY. $\phi_m(j)$ *is multiplicative in* m.

Proof. If $(m, n)=1$, then $(j, mn)=(j, m) \cdot (j, n)$, and also $((j, m), (j, n))=1$. Hence

$$\phi_{mn}(j) = mn \frac{\phi((j, mn))}{(j, mn)} = mn \frac{\phi((j, m) \cdot (j, n))}{(j, m) \cdot (j, n)}$$

$$= m \frac{\phi((j, m))}{(j, m)} \cdot n \frac{\phi((j, n))}{(j, n)} = \phi_m(j) \cdot \phi_n(j).$$

Let N_j $(j=1, \cdots, n)$ be the residue classes mod n. The following two theorems give the properties of residue classes which are used to show multiplicativeness for commutative semigroups.

THEOREM 5. $(m, n)=1$ *if and only if for all* i *and* j, $M_i \cap N_j$ *is nonempty.*

Proof. If $(m, n)=1$, we can solve $xm+i \equiv j \pmod{n}$, so $M_i \cap N_j$ is not empty. If $(m, n)=d>1$, take $j=d$, $i=1$, and the equation $xm+1 \equiv d \pmod{n}$ is impossible, so $M_1 \cap N_d$ is empty.

Of course, the classes $M_i \cap N_j$ form the residue classes of $m \cdot n$, when $(m, n)=1$. The following theorem shows the nature of relative primality of the classes of mn in relation to the m and n classes.

THEOREM 6. *If* $(m, n)=1$, *then* $(M_i \cap N_s, M_j \cap N_t)=1$ *if and only if* $(M_i, M_j)=(N_s, N_t)=1$.

Proof. Let r_1, r_2 be the least positive residues (mod mn) of $M_i \cap N_s$ and $M_j \cap N_t$ respectively. By Theorem 1, we need only show $(r_1, r_2, mn)=1$. Let p be a prime dividing (r_1, r_2, mn), and let p divide say m. Now $r_1 \equiv i \pmod{m}$ and $r_2 \equiv j \pmod{m}$, so p would divide both i and j, along with m, a contradiction to $(i, j, m)=1$. For the converse, if $M_i \cap N_s$ and $M_j \cap N_t$ are relatively prime, then one can find a in $M_i \cap N_s$ and b in $M_j \cap N_t$ such that $(a, b)=1$, and this a and b will serve to show the relative primality of M_i and M_j as well as N_s and N_t.

We now study the application of these ideas to a commutative semigroup S. As usual, we define $a \mid b$ if and only if there is a c in S such that $b=ca$. To say that a is a *unit* means, that $a \mid b$ for all b in S. Let S be partitioned into a finite number of residue classes compatible with multiplication, $S=\bigcup_j M_j$, $M=\{M_j\}$. Let $(a, b)=1$ mean that the only common divisors of a and b are units. Then define, as before, $(M_i, M_j)=1$ as the existence of a in M_i and b in M_j such that $(a, b)=1$; $\phi(M_i)$ = the number of M_j such that $(M_i, M_j)=1$, and $\phi(M)=\min_i \phi(M_i)$.

Now let $N=\{N_j\}$ be another such finite compatible partition. Let $M \cdot N=\{M_i \cap N_j\}$ be the common refinement of all intersections. It is easy to see that this is always compatible, and it is clearly finite. Using the conditions from Theorems 5 and 6 we obtain the following multiplicativeness theorem for semigroups.

THEOREM 7. *If* M *and* N *are two compatible partitions of the semigroup* S *such that* (i) *for all* i *and* j $M_i \cap N_j$ *is not empty*, (ii) $(M_i \cap N_s, M_j \cap N_t)=1$ *if and only if* $(M_i, M_j)=(N_s, N_t)=1$, *then* $\phi(M \cdot N)=\phi(M) \cdot \phi(N)$.

Proof. By condition (i) $M_i \cap N_j$ is a nonempty class of the partition $M \cdot N$. By condition (ii) $\phi(M_i \cap N_s)=$ the number of $M_j \cap N_t$ relatively prime to $M_i \cap N_s=\phi(M_i) \cdot \phi(N_s)$. Hence $\phi(M_i \cap N_s)$ will be minimized when $\phi(M_i)$ and $\phi(N_s)$ are minimized, so $\phi(M \cdot N)=\phi(M) \cdot \phi(N)$.

To sum up, we have defined a ϕ-function which can be thought of as a totient function on the integers mod m, and also as a multiplicative function on the

integers with j fixed. In addition, we have studied the definition of such a function as a multiplicative function on commutative semigroups.

n AND $n+1$ CONSECUTIVE INTEGERS WITH EQUAL SUMS OF SQUARES

W. H. SIMONS, University of California, Davis, and University of British Columbia and
H. L. ALDER, University of California, Davis

In [1] Alder gave a complete set of solutions in positive integers of the equation

$$x^2 + (x+1)^2 + (x+2)^2 + \cdots + (x+n-1)^2 = y^2 + (y+1)^2 + (y+2)^2 + \cdots + (y+n)^2, \tag{1}$$

i.e., the case where the sum of n consecutive squares equals the sum of $n+1$ consecutive squares, for all positive integers n considered in [2], namely where n and $n+1$ are squarefree.

It is the purpose of this paper to give the complete set of solutions of (1) for all n.

As in [1], we rewrite (1) as

$$nx^2 + n(n-1)x - n^2 = (n+1)y^2 + n(n+1)y. \tag{2}$$

Letting $x=y+z$, we can rewrite (2) as $y^2-2n(z-1)y-n(n+z)(z-1)=0$ or $[y-n(z-1)]^2=n^2(z-1)^2+n(n+z)(z-1)$ or

$$[y - n(z-1)]^2 = n(n+1)z(z-1). \tag{3}$$

We now distinguish two cases:

CASE I. $n\equiv 1$ or $2 \pmod 4$.

If $n\equiv 2 \pmod 4$, let $n=2m$ and determine positive integers a and b, with b squarefree, so that

$$m(2m+1) = a^2b. \tag{4}$$

If $n\equiv 1 \pmod 4$, let $n+1=2m$ and determine positive integers a and b, with b squarefree, so that

$$(2m-1)m = a^2b. \tag{5}$$

Substituting either (4) or (5) into (3), we obtain

$$[y - n(z-1)]^2 = 2a^2bz(z-1). \tag{6}$$

Since the left hand side is divisible by a^2, it follows that $y-n(z-1)$ is divisible by a; moreover, since the left hand side is divisible by b and b is square-

free, $y-n(z-1)$ is also divisible by b. We now conclude that $y-n(z-1)$ is divisible by ab. This is obvious if $(a, b)=1$. If, on the other hand, $(a, b)>1$, let p be a prime dividing both a and b and p^{α} the largest power of p dividing a, then the left hand side of (6) is divisible by $p^{2\alpha+1}$ and consequently by $p^{2\alpha+2}$, so that $y-n(z-1)$ is divisible by $p^{\alpha+1}$ and, using the same argument for all primes dividing both a and b, our conclusion follows. Therefore, we can let

$$y - n(z - 1) = abw \tag{7}$$

and, by substitution into (6), obtain $2z(z-1)=bw^2$ or

$$(2z - 1)^2 - 2bw^2 = 1, \tag{8}$$

which is Pell's equation, usually written

$$x^2 - Dy^2 = 1,$$

with $x=2z-1$, $y=w$, $D=2b$. Note that D is not a perfect square, since b is squarefree and not equal to 2. If b were 2, it would follow from (4) or (5) that the product of two consecutive integers is a perfect square which is impossible.

The Pell equation (8) can be most conveniently solved, as in [1], by use of the infinite continued fraction expansion of $\sqrt{2b}$. Since the appropriate numerators and denominators, respectively, of the convergents give all solutions of (8), we have obtained a complete set of solutions of (1) for Case I.

CASE II. $n\equiv 0$ or 3 (mod 4).

If $n\equiv 0$ (mod 4), we let $n=4m$ and determine positive integers a and b, with b squarefree, so that

$$m(4m + 1) = a^2b. \tag{9}$$

If $n\equiv 3$ (mod 4), we let $n+1=4m$ and determine positive integers a and b, with b squarefree, so that

$$(4m - 1)m = a^2b. \tag{10}$$

Substituting either (9) or (10) into (3) we obtain

$$[y - n(z - 1)]^2 = 4a^2bz(z - 1). \tag{11}$$

Since the left-hand side must be divisible by both a and b, we let

$$y - n(z - 1) = abw \tag{12}$$

and obtain $4z(z-1)=bw^2$ or

$$(2z - 1)^2 - bw^2 = 1, \tag{13}$$

which again is Pell's equation. If b is even, all solutions of (1) are obtained by use of the continued fraction expansion of $\sqrt{b}$. If b is odd, however, we obtain all solutions of (1) by using only those solutions of (13) obtained from the continued fraction expansion of $\sqrt{b}$ for which w is even, thus guaranteeing that $2z-1$ is odd.

Example. $n=100$.

Since this is Case II, we let $25\cdot 101=a^2b$, so that $a=5$, $b=101$. Now

$$\sqrt{101} = (10, \overline{20}), \tag{14}$$

so that, if we denote the ith convergent of $\sqrt{101}$ by

$$C_i = \frac{p_i}{q_i}, \tag{15}$$

we find all solutions of (13) for which w is even by $2z-1=p_{2k}$, $w=q_{2k}$, where $k=1, 2, 3, \cdots$.

The first solution, therefore, would be obtained for $k=1$ and can easily be found to be $2z-1=p_2=201$, $w=q_2=20$.

Since the convergents in a continued fraction expansion are related recursively by

$$p_i = a_ip_{i-1} + p_{i-2}$$
$$q_i = a_iq_{i-1} + q_{i-2},$$

and since from (14) the partial quotients a_i (for $i\geqq 2$) are all 20, we have for $i=2k$

$$p_{2k} = 20p_{2k-1} + p_{2k-2} = 20(20p_{2k-2} + p_{2k-3}) + p_{2k-2} = 401p_{2k-2} + 20p_{2k-3}$$
$$= 401p_{2k-2} + (p_{2k-2} - p_{2k-4}) = 402p_{2k-2} - p_{2k-4}.$$

Completely analogously we find $q_{2k}=402q_{2k-2}-q_{2k-4}$. This shows that the complete set of solutions of equation (13) with $b=101$ is given by the following recursion formulae:

$$\begin{aligned} 2z - 1 &= p_{2k} = 402p_{2k-2} - p_{2k-4}, \\ w &= q_{2k} = 402q_{2k-2} - q_{2k-4}, \end{aligned} \tag{16}$$

with $p_2=201$, $q_2=20$.

The solutions for x and y are then given by

$$\begin{aligned} y &= 100(z - 1) + 505w, \\ x &= y + z, \end{aligned} \tag{17}$$

and the solution with smallest x and y is given by $y=20100$, $x=20201$.

The authors wish to acknowledge the help of their students, Mr. S. P. Galovich and Mr. R. D. Hall, in the work on this problem.

PROOF OF SCHERK'S CONJECTURE ON THE REPRESENTATION OF PRIMES

J. L. BROWN, JR., Pennsylvania State University

In Dickson's History ([1], p. 436), this paragraph appears: "H. F. Scherk [2] stated the following empirical theorems: *Every prime of odd rank (the n-th prime* 1, 2, 3, 5, $\cdots$ *being of rank n) can be composed by addition and subtraction of all the smaller primes, each taken once*; *thus*

$$13 = 1 + 2 - 3 - 5 + 7 + 11 = -1 + 2 + 3 + 5 - 7 + 11.$$

Every prime of even rank can be composed similarly, except that the next earlier prime is doubled; *thus*

$$\begin{aligned} 17 &= 1 + 2 - 3 - 5 + 7 - 11 + 2\cdot 13 \\ &= -1 - 2 + 3 - 5 + 7 - 11 + 2\cdot 13." \end{aligned}$$

The purpose of this note is to give a simple proof of Scherk's observations by making use of Bertrand's postulate and a lemma developed earlier by the author [3].

LEMMA. *Let* $f_1=1$, f_2, f_3, $\cdots$ *be a sequence of positive integers satisfying* $f_{m+1} \leqq 1+\sum_1^m f_i$ *for* $m \geqq 1$. *Then, corresponding to any integer n satisfying the inequality* $0 \leqq n < 1+\sum_1^k f_i$, *there exist binary coefficients* $\alpha_i=\alpha_i(n)$ *such that* $n=\sum_1^k \alpha_i f_i$ ($\alpha_i=0$ *or* 1 *for each i*).

A proof of the lemma will be found in [3].

If the sequence of primes (with unity adjoined) is denoted by $p_1=1$, $p_2=2$, $p_3=3$, $p_4=5$, $\cdots$ then the subject theorem has the form

THEOREM (SCHERK). *For each integer* $n \geqq 1$, *there exist coefficients* $\epsilon_i=\epsilon_i(n)$ *such that* $\epsilon_i=+1$ *or* -1 *for each i and*

$$\text{(a)}\quad p_{2n+1} = p_{2n} + \sum_1^{2n-1} \epsilon_i p_i, \qquad \text{(b)}\quad p_{2n} = 2p_{2n-1} + \sum_1^{2n-2} \epsilon_i p_i.$$

Proof. By Bertrand's postulate, $p_{k+1} \leqq 2p_k$ for $k \geqq 1$ with strict inequality for $k>1$. Making use of this fact, it is easily established by induction that

$$p_{k+1} \leqq 1 + \sum_1^k p_i \qquad (k \geqq 1). \tag{1}$$

For $n \geqq 1$, we have

$$0 < p_{2n+1} - p_{2n} \leqq p_{2n} \leqq 1 + \sum_1^{2n-1} p_i,$$

so that

$$0 < \tfrac{1}{2}\left(p_{2n+1} - p_{2n} + \sum_1^{2n-1} p_i\right) < 1 + \sum_1^{2n-1} p_i.$$

It follows from the lemma that the integer

$$\tfrac{1}{2}\left(p_{2n+1} - p_{2n} + \sum_{1}^{2n-1} p_i\right)$$

may be expanded in the form

$$\tfrac{1}{2}\left(p_{2n+1} - p_{2n} + \sum_{1}^{2n-1} p_i\right) = \sum_{1}^{2n-1} \gamma_i p_i \qquad (\gamma_i \text{ binary}). \tag{2}$$

Equivalently,

$$p_{2n+1} = p_{2n} + \sum_{1}^{2n-1} (2\gamma_i - 1)p_i \qquad (n \geqq 1), \tag{3}$$

which, on noting that $2\gamma_i - 1 = \pm 1$ for each i, proves (a).

To establish (b), we observe that for $n \geqq 1$,

$$0 \leqq 2p_{2n-1} - p_{2n} = p_{2n-1} + (p_{2n-1} - p_{2n}) < p_{2n-1} \leqq 1 + \sum_{1}^{2n-2} p_i,$$

so that $0 \leqq \frac{1}{2}(2p_{2n-1} - p_{2n} + \sum_1^{2n-2} p_i) < 1 + \sum_1^{2n-2} p_i$. Again, the lemma guarantees binary coefficients γ_i such that

$$\tfrac{1}{2}\left(2p_{2n-1} - p_{2n} + \sum_{1}^{2n-2} p_i\right) = \sum_{1}^{2n-2} \gamma_i p_i,$$

or equivalently,

$$p_{2n} = 2p_{2n-1} + \sum_{1}^{2n-2} (1 - 2\gamma_i)p_i \qquad (n \geqq 1). \tag{4}$$

Since $1 - 2\gamma_i = \pm 1$ for each i, the proof of (b) is complete.

Lastly, we prove a related result concerning the expansion of arbitrary positive integers in terms of certain complete sequences. (A sequence $\{f_i\}$ of positive integers is said to be *complete* if and only if every positive integer n can be represented in the form $n = \sum_1^\infty \alpha_i f_i$, where each $\alpha_i = \alpha_i(n)$ is a binary coefficient.)

THEOREM. *Let $\{u_i\}_1^\infty$ be an increasing sequence of positive integers which is complete and such that the equation $u_i \equiv 1 \pmod 2$ is satisfied for infinitely many distinct values of i. Then every integer $n > 0$ has a representation in the form*

$$n = \sum_{1}^{k(n)} \epsilon_i u_i, \qquad \textit{with } \epsilon_i = \pm 1 \textit{ for each } i. \tag{5}$$

Proof. Given an integer $n > 0$, choose k_0 as the smallest integer such that

$$\text{(i) } n \leqq \sum_{1}^{k_0} u_i \quad \text{and} \quad \text{(ii) } n + \sum_{1}^{k_0} u_i \equiv 0 \pmod 2.$$

Since $\{u_i\}$ is an increasing complete sequence, it is known ([3], Theorem 1, p. 558) that $u_1=1$ and $u_{n+1}\leqq 1+\sum_1^n u_i$ for $n\geqq 1$. Applying the lemma to the integer $\frac{1}{2}(n+\sum_1^{k_0} u_i)$ yields

$$\tfrac{1}{2}\left(n+\sum_1^{k_0} u_i\right)=\sum_1^{k_0}\gamma_i u_i$$

with binary coefficients γ_i, or equivalently,

$$n=\sum_1^{k_0}(2\gamma_i-1)u_i, \tag{6}$$

which is in the required form (5).

As a special case of this theorem, it follows that every integer n can be written in the form

$$n=\sum_1^{k(n)}\epsilon_i p_i, \qquad \epsilon_i=\pm 1,$$

where the sequence $\{p_i\}$ is the sequence of primes (plus unity) used previously.

If the equation $u_i\equiv 1 \pmod 2$ is not satisfied for infinitely many i, the conclusion of the latter theorem is not necessarily valid. For, the sequence $u_i=2^{i-1}$ $(i=1, 2, \cdots)$ is certainly increasing and complete, but any sum of the form $\sum_1^{k(n)}\epsilon_i u_i=\sum_1^{k(n)}\epsilon_i 2^{i-1}$ has odd parity, and hence no even integers can be represented in the form (5) for this particular sequence.

An alternate treatment of Scherk's theorem and additional references may be found in Sierpiński ([4] pp. 140–142).

ON THE NILPOTENCY OF ALGEBRAS

ALEXANDER ABIAN, Ohio State University

In [1] it is established that if every basis element of a finite dimensional linear associative algebra over a field of *characteristic zero* is nilpotent then the algebra is nilpotent.

Below we establish the same result without requiring that the characteristic of the field be zero.

THEOREM. *A finite dimensional linear associative algebra A (over any field) is nilpotent if and only if A has a basis every element of which is nilpotent.*

Proof. The necessity follows trivially since every element of a nilpotent algebra is nilpotent.

To prove the sufficiency, let $\{b_1, \cdots, b_n\}$ be a basis of the algebra A such that for every $i=1, \cdots, n$

(1) b_i *is nilpotent.*

Assume, on the contrary, that A is not nilpotent and let N be the radical of A. Thus, by our assumption $A \neq N$. Clearly, A/N is a semi-simple algebra. Without loss of generality, for some $k \leqq n$, we may take $\{b_1+N, \cdots, b_k+N\}$ as a basis of A/N.

Since A/N is semi-simple, for some $h \leqq k$, it is a direct sum of simple algebras $S_1, \cdots, S_h$, where for every $i=1, \cdots, h$ a subset $\mathfrak{s}_i$ of $\{b_1+N, \cdots, b_k+N\}$ serves as a basis of S_i.

In view of (1), for every $i=1, \cdots, h$, every element of $\mathfrak{s}_i$ is nilpotent (in the algebra S_i). In particular

(2) *every element of* $\mathfrak{s}_1$ *is nilpotent.*

Since S_1 is a simple algebra, S_1 is a direct product of a total matric algebra M and a division algebra D. Let $\mathfrak{M}=\{m_{11}, \cdots, m_{tt}\}$ be a basis of M with

(3) $m_{ij}m_{hk} = 0$ *if* $j \neq h$ *and* $m_{ij}m_{jk} = m_{ik}$ *for* $i, j, h, k = 1, \cdots, t$.

Moreover, let $\mathfrak{D}=\{d_1, \cdots, d_p\}$ be a basis of D such that

(4) $$\mathfrak{s}_1 = \{m_{uv}d_w \mid m_{uv} \in \mathfrak{M} \quad \text{and} \quad d_w \in \mathfrak{D}\}$$

and where

(5) $m_{uv}d_w = d_w m_{uv}$ *for every* $m_{uv} \in \mathfrak{M}$ *and every* $d_w \in \mathfrak{D}$.

In view of (3), however, each of the elements m_{ii} with $i=1, \cdots, t$ is idempotent and hence not nilpotent. Also, since D is a division algebra none of the elements d_w with $w=1, \cdots, p$ is a divisor of zero. Therefore, in view of (5) we conclude

(6) *there exists an element of* $\{m_{uv}d_w \mid m_{uv} \in \mathfrak{M}$ *and* $d_w \in \mathfrak{D}\}$ *which is not nilpotent.*

Comparing (3), (4) and (6) we conclude that our assumption leads to a contradiction. Hence our assumption is false and $A=N$. Thus, indeed A is a nilpotent algebra, as desired.

ON PSEUDOPRIMES WHICH ARE PRODUCTS OF DISTINCT PRIMES

K. SZYMICZEK, Katowice, Poland

A composite number n is said to be pseudoprime if $n \mid 2^n - 2$. Let $P(x)$ denote the number of pseudoprimes $\leqq x$ and let $P_k(x)$ denote the number of square-free pseudoprimes $\leqq x$ having k distinct prime factors. P. Erdös [1] proved that for x sufficiently large,

$$P(x) < 2x \exp\{-\tfrac{1}{3}(\log x)^{1/4}\}, \tag{1}$$

and stated that there is an estimation of $P(x)$ from below $P(x) > c \log x$, which is due to D. H. Lehmer.

In the present paper I prove the inequality $P_2(x) > \frac{1}{4} \log x$, and also estimations of $P_k(x)$ and $P(x)$ from below. As a consequence of (1) I shall prove that the series $\sum 1/P_n$, where P_n is the nth pseudoprime, is convergent.

Now we prove the following lemma.

LEMMA. *If k is a natural number $\geqq 2$ and x is sufficiently large, then*

$$P_{k+1}(x) \geqq P_k(\log x). \tag{2}$$

Proof. Let n be a pseudoprime which is product of $k \geqq 2$ distinct odd primes. In view of a theorem of Zsigmondy [3], there exists a prime $p > n$ such that $p \mid 2^{n-1} - 1$ and $n - 1 \mid p - 1$. Thus,

$$np \mid 2^{n-1} - 1. \tag{3}$$

On the other hand, $np - 1$ is divisible by $n - 1$, since $n - 1 \mid p - 1$ and $np - 1 = n(p-1) + n - 1$. Then by (3) we get

$$np \mid 2^{np-1} - 1,$$

i.e. np is a pseudoprime which is product of $k+1$ distinct odd primes. We observe that if n and m are natural numbers, $n \neq m$, and p, q are primes such that $p > n$, $q > m$, then $np \neq mq$. If $np = mq$ and $p > n$ then m is divisible by p, hence $m \geqq p$, and we get $m > n$. In view of symmetry $m < n$, which is contradictory. Consequently $np \neq mq$. Thus, if n, m are distinct pseudoprimes having $k \geqq 2$ distinct prime factors, the adequate pseudoprimes np and mq are distinct, too.

From (3) it follows that

$$p \mid (2^{(n-1)/2} - 1)(2^{(n-1)/2} + 1),$$

and therefore

$$p \leqq 2^{(n-1)/2} + 1 < e^{n/2}.$$

Thus, if $n \leqq \log x$ then $pn < e^{1/2 \log x} \log x = x^{1/2} \log x < x$. Hence, for every pseudoprime $n = p_1 \cdots p_k \leqq \log x$ there exists at least one pseudoprime $p_1 \cdots p_k p < x$. Thus, by the above remark, we obtain (2).

THEOREM 1. *If* $x \geqq 2^{2^2}-1$, *then*

$$P_2(x) > \tfrac{1}{4} \log x. \tag{4}$$

Proof. Let m be an odd number >3. In view of Zsigmondy's [3] theorem there exist prime numbers p and q such that

$$p \mid 2^m - 1,\ q \mid 2^m + 1,\ m \mid p - 1,\ 2m \mid q - 1. \tag{5}$$

Since p and m are odd, $2m \mid p-1$. Further,

$$p \mid 2^m - 1 \mid 2^{q-1} - 1,\ q \mid 2^{2m} - 1 \mid 2^{p-1} - 1:$$

hence, by a theorem of J. H. Jeans [2], pq is pseudoprime. From (5) we get

$$pq < 2^{2m} - 1.$$

Thus, for every odd number $m>3$ there exists a pseudoprime of the form pq which is less than $2^{2m}-1$.

Let x be sufficiently large and m be the greatest odd number for which

$$2^{2m} - 1 \leqq x. \tag{6}$$

By the above argument, there are at least $(m-3)/2$ of pseudoprimes of the form pq less than x, i.e.

$$P_2(x) \geqq \frac{m-3}{2}.$$

We see that there are at least $(m-3)/2$ pseudoprimes pq, where p, q are primes satisfying (5), whereas there exist pseudoprimes pq not satisfying (5), for example:

$$17 \cdot 257,\ (17 \mid 2^8 - 1,\ 257 \mid 2^8 + 1),$$

$$23 \cdot 89,\ (23 \cdot 89 = 2^{11} - 1).$$

We also remark that for $m=11$ there are two pseudoprimes satisfying (5), namely $23 \cdot 683$ and $89 \cdot 683$. Thus, if $x \geqq 2^{2^2}-1$, we may write

$$P_2(x) \geqq \frac{m-3}{2} + 3 > \frac{m+2}{2}. \tag{7}$$

From the definition of m in (6) it follows that

$$x < 2^{2(m+2)} - 1 < e^{2(m+2)},$$

whence $m+2 > \frac{1}{2} \log x$, which, together with (7) gives (4), and the theorem is proved.

REMARK. It may be easily shown that the inequality (4) holds for $x \geqq 1387$, but not for any other x: $1 < x < 1387$.

THEOREM 2. *If k is a natural number $\geqq 2$ and x is sufficiently large, then $P_k(x) > \frac{1}{4}\log_{k-1} x$, where $\log_k x$ denote the k times iterated logarithm.*

Proof. The statement can be easily proved by induction on k if one applies Theorem 1 and our lemma.

THEOREM 3. *If k is a natural number and x is sufficiently large, then*

$$P(x) > \tfrac{1}{4}\log\left\{x\prod_{n=1}^{k}\log_n x\right\}.$$

Proof. For sufficiently large x, $P(x) > P_2(x) + P_3(x) + \cdots + P_{k+2}(x)$, whence, by Theorem 2,

$$\begin{aligned} P(x) &> \tfrac{1}{4}\{\log x + \log_2 x + \cdots + \log_{k+1} x\} \\ &= \tfrac{1}{4}\log\left\{x\prod_{n=1}^{k}\log_n x\right\}. \end{aligned}$$

Now we prove another result.

THEOREM 4. *The series $\sum 1/P_n$, where P_n is the n-th pseudoprime, is convergent.*

Proof. If we put $x = P_n$ then the right hand side of (1) becomes

$$n < 2P_n \exp\{-\tfrac{1}{3}(\log P_n)^{1/4}\}.$$

Since $n < P_n$, we have

$$\frac{1}{P_n} < \frac{2}{n\exp\{\frac{1}{3}(\log n)^{1/4}\}}. \tag{8}$$

On the other hand, for large m, $m^{1/4} > 4\log m$, and thus for sufficiently large n,

$$(\log n)^{1/4} > 4\log\log n.$$

Hence $\frac{1}{3}(\log n)^{1/4} > \log(\log n)^{4/3}$, and

$$\exp\{\tfrac{1}{3}(\log n)^{1/4}\} > (\log n)^{4/3}. \tag{9}$$

From (8) and (9) we get

$$\frac{1}{P_n} < \frac{2}{n(\log n)^{4/3}},$$

and Theorem 4 follows from the well-known convergence of $\sum 2/\{n(\log n)^{4/3}\}$.

It is easy to add restrictions on K, f_k, X_k, Y_k such that (B) alone is a necessary and sufficient condition in Theorem 2. We have, for example, the following.

COROLLARY. *Suppose that X_k, Y_k are nonempty, connected, metrizable spaces for all $k \in K$, and that f_k is nonconstant for at least two values of k. Then f is closed iff f_k is closed and $f_k^{-1}(y_k)$ is compact for all $y_k \in Y_k$, $k \in K$.*

INTEGRAL PART AND FACTORIAL IN CERTAIN EUCLIDEAN DOMAINS

J. CHIDAMBARASWAMY, University of California, Berkeley (Now at University of Toledo, Ohio)

The result "The exponent of the highest power of a prime p that divides $n!$ is $\sum_{k=1}^{\infty} [n/p^k]$" is well known. The purpose of this note is to define integral part and factorial in certain Euclidean domains and establish the above result in those domains.

For simplicity, we select the domain G of Gaussian integers as a prototype of the domains (see the remark at the end) in which the above result can be stated. Let us recall that G consists of all complex numbers $a+bi$, where a and b are rational integers, that the multiplicative group of units of G consists of the numbers ± 1, $\pm i$, and that the quotient field F of G is the set of all complex numbers $r+si$, where r and s are rational numbers. We extend the norm function N usually defined on the nonzero numbers of G by $N(a+bi)=a^2+b^2$ to the nonzero numbers of F by saying $N(r+si)=r^2+s^2$; this is equivalent to saying that if

$$r + si = (a + bi)/(c + di), \quad 0 \neq a + bi \in G, \quad 0 \neq c + di \in G,$$

then $N(r+si)=N(a+bi)/N(c+di)$. We also extend the usual relation of associativity in G to F by saying that $r+si$ is associated to $r'+s'i$ if there exists a unit η of G such that $r+si=\eta(r'+s'i)$. This is an equivalence relation in F and so it induces a partition of F into various equivalence classes, each class other than the zero class (the class whose only member is zero) containing 4 associated numbers i.e. $\pm(a+bi)$, $\pm i(a+bi)$. We pick one number from each of these nonzero classes and denote by P the set of numbers so picked, so that no two numbers of P are associated and each nonzero number of F is associated to exactly one number of P. In fact, it is readily verified that we can take for P the set of all those numbers $r+si$ of F with $r>0$, $s \geqq 0$ and this we shall do for definiteness. We call Gaussian integers of P the P-Gaussian integers.

DEFINITION 1. *For $r+si\in F$, the integral part of $r+si$, denoted by $[r+si]$, is the number of P-Gaussian integers $x+yi$ with $N(x+yi)\leqq N(r+si)$ in the case $N(r+si)\geqq 1$, and is 0 otherwise.*

We observe that associated numbers have the same integral part. Also, since the number of representations of a positive integer n as a sum two squares of integers is $4\sum_{d^2|n} V(n/d^2)$, where $V(n)$ is the number of solutions (mod n) of the congruence $x^2\equiv -1 \pmod{n}$, and since with $x+yi$ all its associates have the same norm, it follows that for any $r+si\in F$,

$$[r+si]=\sum_{j=1}^{[r^2+s^2]}\sum_{d^2|j} V(j/d^2).$$

DEFINITION 2. *For $r+si\in F$, the factorial of $r+si$, denoted by $(r+si)!!$ is the product of all P-Gaussian integers $x+yi$ with $N(x+yi)\leqq N(r+si)$ in case $N(r+si)\geqq 1$, and is 1 otherwise.*

For any $0\neq a+bi\in G$, and any $r+si\in F$, let $M(a+bi, r+si)$ denote the number of multiples of $a+bi$ which are in P and whose norm is less than or equal to that of $r+si$.

THEOREM 1. (1) $M(a+bi, r+si)=[(r+si)/(a+bi)]$.

Proof. Let $m=[r+si]$, and $l=[(r+si)/(a+bi)]$. If $m=0$, both sides of (1) are zero. If $m\geqq 1$, let x_n+y_ni, $1\leqq n\leqq m$ be all the P-Gaussian integers with $N(x_n+y_ni)\leqq N(r+si)$, and a_k+b_ki, $1\leqq k\leqq l$, be all the P-Gaussian integers with $N(a_k+b_ki)\leqq N((r+si)/(a+bi))$.

Clearly, by the definition of P and the fact that the norm of the product of two numbers of F is equal to the product of their norms, there is a 1-1 correspondence between the numbers x_j+y_ji which are divisible by $a+bi$ and the numbers a_k+b_ki. The correspondence can be expressed as

$$(a_k+b_ki)(a+bi)\eta_{kj}=x_j+y_ji,$$

where η_{kj} is a unit. The theorem is clear.

THEOREM 2. *For any $r+si\in F$, and any prime $a+bi\in G$, the exponent of the highest power of $a+bi$ that divides $(r+si)!!$ is*

$$\sum_{k=1}^{\infty}[(r+si)/(a+bi)^k]. \tag{2}$$

Proof. Since $N(a+bi)>1$, (2) terminates. Using the same notation as in the proof of Theorem 1, the result is clear if $m=0$ or $m=1$. If $m\geqq 2$, by Definition 2 and the meaning of the notation x_n+y_ni,

$$(r+si)!!=(x_1+y_1i)(x_2+y_2i)\cdots(x_m+y_mi). \tag{3}$$

Now, the right hand side of (3), by the proof of Theorem 1, can be written as

$$\beta(a+bi)^{[(r+si)/(a+bi)]}((r+si)/(a+bi))!!,$$

where β is an associate of the product of all numbers in the right hand side of (3) which are not divisible by $a+bi$. The rest of the proof is obvious.

REMARK. Clearly what we have done can be done in any Euclidean domain E in which the following conditions hold.

(i) The norm function is multiplicative, i.e., $N(ab)=N(a)N(b)$.

(ii) For each positive integer j, $\{x\in E: N(x)=j\}$ is finite.

(iii) $N(e)>0$ (i.e., $N(e)=1$ by (i)), e being the identity of E.

AN OBSERVATION ON THE DISTRIBUTION OF PRIMES

M. STEIN AND S. M. ULAM, University of California, Los Alamos Scientific Laboratory

Primes up to 100,000,000 have been stored on a rather fast access memory disc connected with a computer, MANIAC II, in our Laboratory. We have looked at some properties of the distribution of primes when the sequence is "compressed" by dividing each prime by its logarithm and taking the nearest integer to this quotient. Of several properties which this new sequence seems to show, the following is perhaps most striking.

It can be stated as follows: For each integer k consider the interval between k and $k+1+E(\log k)$. For some k's there will be no prime in this interval. For some others there will be exactly one prime in this range. For other k's there will be exactly 2 primes, etc. We consider the frequencies of these classes. Let $\gamma_0(n)$ be, therefore, the ratio to n of the number of all k's from 1 to n, such that there is no prime in the range between k and $k+E(\log k)+1$. Actually the interval examined by the machine was from k to $k+E(\log^2 k/\log k-1)$. Similarly we define $\gamma_1(n)$, $\gamma_2(n)$, etc. We have tabulated the γ's in intervals of 10,000 up to $n=100{,}000{,}000$.

It seems that they approach definite limits.

n	γ_0	γ_1	γ_2	γ_3	γ_4	γ_5	γ_6	γ_7

The figures in the Table are rounded to four decimals. We have accumulated our statistics by counting in contiguous intervals of length given above.

These numbers do not appear, at least as yet, to approach a Poisson distribution. γ_0 is smaller and γ_1 is larger than the Poisson value and the tail of the distribution seems to go down to zero faster. There is no proof, of course, of the *existence* of the limit of the γ's, but the impression which the full data give is certainly that they do exist. The first time when six primes appear in our range is somewhere after 22579983 and before 22589996. Up to our $n=10^8$ there is not a single case of seven primes in our intervals. Presumably, for every ℓ, there will exist ℓ primes in this range for sufficiently great n, but the frequency of these in the set of all integers goes to zero extremely fast with increasing ℓ.

We are planning to obtain other statistical data about the distribution of these "compressed" or scaled primes.

This work was performed under the auspices of the U. S. Atomic Energy Commission.

A CONDITION FOR A RING TO BE BOOLEAN

D. L. BARNETT, Aerospace Research Laboratories, Wright-Patterson Air Force Base, Ohio

The purpose of this note is to show that on a (not necessarily associative) ring R with unit it is impossible to introduce a third nontrivial binary operation $\circ$ which is distributive on opposite sides with respect to the ring addition and multiplication, and such that R has an identity element under $\circ$. In fact, the introduction of $\circ$ on R forces R to be Boolean and $\circ$ to coincide with the ring multiplication. In what follows, the letters x, y, z will be used to denote arbitrary elements of a ring.

THEOREM. *Let R be a ring with unit* 1 *and let R be closed under a binary operation $\circ$ with identity element e. Let $\circ$ satisfy*

$$(x + y) \circ z = (x \circ z) + (y \circ z),$$
$$x \circ (yz) = (x \circ y)(x \circ z).$$

Then R is a Boolean ring, $e=1$, and $x \circ y = xy$.

The proof of the theorem will consist of a series of lemmas, where besides the usual ring axioms, the above two one-sided distributive laws are used repeatedly.

LEMMA 1. $(1 \circ 1)(x \circ y)+(x \circ 1)(1 \circ y)=0$.

Proof. $(1 \circ 1)(1 \circ y) + (x \circ 1)(x \circ y) = 1 \circ (1y) + x \circ (1y) = (1 + x) \circ (1y)$ $=((1+x) \circ 1)((1+x) \circ y)=((1 \circ 1)+(x \circ 1))((1 \circ y)+(x \circ y))=(1 \circ 1)(1 \circ y)$ $+(1 \circ 1)(x \circ y)+(x \circ 1)(1 \circ y)+(x \circ 1)(x \circ y)$, and the lemma is obtained by comparing the beginning and the end of this equality.

LEMMA 2. $1 \circ 1=1$.

Proof. $1 \circ 1 = 1(1 \circ 1) = (1 \circ e)(1 \circ 1) = 1 \circ (e1) = 1 \circ e = 1$.

LEMMA 3. *R has characteristic two.*

Proof. Set $x = y = 1$ in Lemma 1 and use Lemma 2 to obtain $1+1=0$.

LEMMA 4. $e = 1$.

Proof. From Lemma 1, $0 = (1 \circ 1)(e \circ e) + (e \circ 1)(1 \circ e) = 1e + 1 \cdot 1 = e + 1$. This and Lemma 3 imply $e = 1$.

LEMMA 5. *R is a Boolean ring, i.e. $x^2 = x$.*

Proof. $x = x \circ 1 = x \circ (1 \cdot 1) = (x \circ 1)(x \circ 1) = xx$.

LEMMA 6. $x \circ y = xy$.

Proof. From Lemmas 1, 2, and 4,

$$0 = (1 \circ 1)(x \circ y) + (x \circ 1)(1 \circ y) = 1(x \circ y) + xy = (x \circ y) + xy,$$

i.e. $x \circ y = xy$, because R has characteristic two. The theorem is proved.

Notice that the associative law of multiplication was not used in the above. It can be proved from what we have assumed and proved, using the fact that multiplication is distributive over multiplication (true because the operation $\circ$ turned out to be multiplication).

CLASSROOM NOTES

TRIANGLES WITH RATIONAL SIDES AND ANGLE RATIOS

D. E. DAYKIN AND A. OPPENHEIM, University of Malaya

Let m, n be arbitrary fixed coprime positive integers, and let T denote the set of all triangles ABC with angles

$$(1) \qquad A = m\theta, \quad B = n\theta, \quad C = \pi - (m+n)\theta, \quad \text{where} \quad 0 < \theta < \pi/(m+n),$$

so that $nA = mB$. An interesting problem in number theory is that of finding the set S of integer sided triangles of T whose sides have greatest common divisor 1. For $m/n = 1/3$, $2/3$ a solution of this problem due to one of us (A.O.) was given in [1], and we present here the primitive general solution in Theorem 1 below. The key to the problem is the

LEMMA. *A triangle ABC of T has rational side ratios if and only if* $\cos\theta$ *is rational.*

Proof. Suppose first that the sides a, b, c of a triangle of T are rational. Then by the cosine rule $\cos m\theta$, $\cos n\theta$, $\cos (m+n)\theta$ are rational. Also by the sine rule

there is a real number ρ such that $\rho \sin m\theta$, $\rho \sin n\theta$, $\rho \sin (m+n)\theta$ are a, b, c respectively, and hence are rational. Since $\cos^2 m\theta + \sin^2 m\theta = 1$ the number ρ^2 is rational. Now

$$\cos(m-n)\theta = \cos m\theta \cos n\theta + \rho^{-2}(\rho \sin m\theta)(\rho \sin n\theta),$$
$$\rho \sin(m-n)\theta = (\rho \sin m\theta)\cos n\theta - \cos m\theta(\rho \sin n\theta),$$

and so $\cos (m-n)\theta$, $\rho \sin (m-n)\theta$ are rational. Repeating this argument like Euclid's algorithm shows, because m, n are coprime, that $\cos \theta$ is rational. The converse result follows in a similar way, and this proves the lemma.

Next let $\phi(r/s; t)$ denote the integer

$$\phi(r/s; t) = \text{Imag}\{[r + i(s^2 - r^2)^{1/2}]^t/(s^2 - r^2)^{1/2}\} \quad \text{for } r, s, t = 1, 2, \cdots. \tag{2}$$

Then if $\cos \theta = r/s$, for $t = m$, n, $m+n$ the number

$$\begin{aligned}(s^{m+n-1} \sin t\theta)/\sin \theta &= s^{m+n}(s^2 - r^2)^{-1/2} \sin t\theta \\ &= s^{m+n}(s^2 - r^2)^{-1/2}\,\text{Imag}\{[\cos \theta + i \sin \theta]^t\} \\ &= s^{m+n-t}\phi(r/s; t),\end{aligned} \tag{3}$$

is an integer. The lemma shows that all rational sided triangles of T may be determined by taking in (1) those angles θ which have rational cosines. Moreover the sides of these triangles will then be proportional to $\sin m\theta$, $\sin n\theta$, $\sin (m+n)\theta$, and these numbers appear in (3). Hence we have proved the first part of

THEOREM 1. *The sides a, b, c respectively of the triangles of S are obtained by dividing the integers*

$$s^n\phi(r/s; m), \qquad s^m\phi(r/s; n), \qquad \phi(r/s; m+n), \tag{4}$$

by their greatest common divisor g, when r, s range over positive integral values such that $(r, s) = 1$ and $\cos (\pi/(m+n)) < r/s < 1$. Moreover $g = 1$ if s is odd but $g = 2^{m+n-1}$ if s is even.

To complete the proof we need only discuss the greatest common divisor g of the numbers (4) for fixed r, s. Let $\cos \theta = r/s$ and

$$\psi(t) = \psi(r/s; t) = s^t \cos t\theta \qquad \text{for } t = 1, 2, \cdots,$$

then $\psi(1) = r$, $\psi(2) = 2r^2 - s^2$ and $\psi(t+1) = 2r\psi(t) - s^2\psi(t-1)$ for $t > 1$, and so by induction $\psi(t)$ is an integer for $t \geqq 1$.

For convenience we suppose that $m > n$ and write $\phi(t)$ for $\phi(r/s; t)$. Then by (3),

$$\phi(t) = (s^{t-1} \sin t\theta)/\sin \theta \qquad \text{for } t = 1, 2, \cdots$$

and, if M is any integer,

$$s^M\phi(m-n) = s^{M-3n}(s^n\phi(m))\psi(n) - s^{M-m-2n}(s^m\phi(n))\psi(m). \tag{5}$$

Now suppose that p is a prime which divides $s^n\phi(m)$ and $s^m\phi(n)$. Then, since $\psi(t)$ is an integer, (5) shows that p divides $s^M\phi(m-n)$ for M sufficiently large, $M \geqq m+2n$. Repeating this argument like Euclid's algorithm, since m, n are coprime, we find that p divides $s^N\phi(1) = s^N$ for N sufficiently large, and so p divides s. This result also holds if $m=n$ for then $m=1$. Now

$$\phi(1) = 1, \quad \phi(2) = 2r \quad \text{and} \quad \phi(t+1) = 2r\phi(t) - s^2\phi(t-1) \quad \text{for } t > 1, \tag{6}$$

and by induction on these relations, or directly from (2), we see that for $t \geqq 1$,

$$\phi(t) = qs + (2r)^{t-1}, \tag{7}$$

for some integer $q=q(t)$. Hence if p also divides $\phi(m+n)$, since it divides s and $(r, s)=1$, it follows by (7) that $p=2$. Thus we have shown that the greatest common divisor g of the numbers (4) is $g=2^u$ for some integer u, and $u=0$ when s is odd.

If 4 divides s, then r is odd and for $t \geqq 1$, by induction on (6), the highest power of 2 which divides $\phi(t)$ is 2^{t-1}. If s is even but not divisible by 4, then the highest power of 2 which divides $\phi(t)$ is 2^{t-1} when t is not divisible by 3, but 2^t divides $\phi(t)$ when 3 divides t. Since $(m, n)=1$ it follows that $g=2^{m+n-1}$ whenever s is even, and the theorem is proved.

A SIMPLE UNIQUENESS THEORY FOR ORDINARY LINEAR HOMOGENEOUS DIFFERENTIAL EQUATIONS

L. E. PURSELL, Grinnell College

In the following we outline a development of the uniqueness of a solution to an initial value problem in ordinary linear homogeneous differential equations which is suitable for a brief introduction to ordinary differential equations (such as a unit in a first year calculus course). Our main theorem is obtained by the simple artifice of applying the method of variation of parameters to a *homogeneous* equation. To simplify exposition we will consider only second order linear differential equations, but our theorems and proofs can be extended easily to higher order equations.

We assume that the student is familiar with the elementary theory of determinants and systems of linear algebraic equations; he has learned how to use the characteristic polynomial $r^2+Pr+Q=0$ to find pairs ϕ_1, ϕ_2 of solutions to the differential equation $y''+Py'+Qy=0$ (P and Q constants) such that the Wronskian, $W(\phi_1, \phi_2; x)=\phi_1(x)\phi_2'(x)-\phi_1'(x)\phi_2(x)$, is different from zero for all x. (Note: The notion of linear independence does not appear explicitly in our theory.) He has also been shown that if ϕ_1 and ϕ_2 are solutions of a linear homogeneous differential equation, then so is $C_1\phi_1+C_2\phi_2$ where C_1 and C_2 are constants. We then prove:

THEOREM 1. *If P and Q are constants (or continuous functions of x on an interval I) and ϕ_1, ϕ_2, and f are solutions of the differential equation*

$$y'' + Py' + Qy = 0$$

on I such that $W(\phi_1, \phi_2; x) \neq 0$ for all x in I, then there exist constants C_1 and C_2 such that

$$f(x) = C_1\phi_1(x) + C_2\phi_2(x) \qquad \text{for all } x \text{ in } I.$$

Proof. Since $W(\phi_1, \phi_2; x) \neq 0$, the system of equations

$$f(x) = u_1(x)\phi_1(x) + u_2(x)\phi_2(x) \tag{1a}$$

$$f'(x) = u_1(x)\phi_1'(x) + u_2(x)\phi_2'(x) \tag{1b}$$

has a unique pair of solutions $(u_1(x), u_2(x))$ for each x in I. From Cramer's rule:

$$u_1(x) = \frac{f(x)\phi_2'(x) - f'(x)\phi_2(x)}{W(\phi_1, \phi_2; x)}$$

and

$$u_2(x) = \frac{\phi_1(x)f'(x) - \phi_1'(x)f(x)}{W(\phi_1, \phi_2; x)};$$

we see that u_1 and u_2 are differentiable since ϕ_1, ϕ_2, and f are solutions of a second order differential equation, and hence are twice differentiable. Differentiating (1b) and then substituting into the differential equation we obtain

$$\begin{aligned} 0 &= f'' + Pf' + Qf \\ &= (u_1'\phi_1' + u_2'\phi_2' + u_1\phi_1'' + u_2\phi_2'') + P(u_1\phi_1' + u_2\phi_2') + Q(u_1\phi_1 + u_2\phi_2) \\ &= (u_1'\phi_1' + u_2'\phi_2') + u_1(\phi_1'' + P\phi_1' + Q\phi_1) + u_2(\phi_2'' + P\phi_2' + Q\phi_2). \end{aligned}$$

Hence

$$0 = u_1'(x)\phi_1'(x) + u_2'(x)\phi_2'(x) \qquad \text{for all } x \text{ in } I. \tag{2a}$$

But if we differentiate (1a) and subtract (1b) from the result we obtain:

$$0 = u_1'(x)\phi_1(x) + u_2'(x)\phi_2(x) \qquad \text{for all } x \text{ in } I. \tag{2b}$$

Since the determinant, $W(\phi_1, \phi_2; x)$, of the system of equations (2b, 2a) is different from zero for all x in I, we have $u_1'(x) = 0$ and $u_2'(x) = 0$ for all x in I. Hence $C_1 = u_1(x)$ and $C_2 = u_2(x)$ are constants.

THEOREM 2. *If there exists a pair (ϕ_1, ϕ_2) of solutions to the differential equation $y'' + Py' + Qy = 0$ on an interval I where P and Q are constants (or continuous functions of x) for which $W(\phi_1, \phi_2; x) \neq 0$ for all x in I, x_0 is any point in I, and a and b are any two real numbers, then* (i) *there is a unique solution f of the differential equation on I such that $f(x_0) = a$ and $f'(x_0) = b$. Also if g is any solution of*

the differential equation on an interval J containing x_0 which satisfies these initial conditions, then (ii) $g(x)=f(x)$ *for all* x *in* $I\cap J$.

Proof. (i) By the previous theorem every solution of the differential equation on I is of the form $f(x)=C_1\phi_1(x)+C_2\phi_2(x)$. If we substitute this linear combination into the initial conditions we have:

$$a = C_1\phi_1(x_0) + C_2\phi_2(x_0) \tag{3a}$$

$$b = C_1\phi_1'(x_0) + C_2\phi_2'(x_0). \tag{3b}$$

Since $W(\phi_1, \phi_2; x_0)=0$, this system of equations has a unique pair (C_1, C_2) of solutions. Hence f exists uniquely on I.

(ii) By Theorem 1 there exist constants k_1 and k_2 such that $g=k_1\phi_1+k_2\phi_2$ on $I\cap J$. Then

$$a = g(x_0) = k_1\phi_1(x_0) + k_2\phi_2(x_0)$$

$$b = g'(x_0) = k_1\phi_1'(x_0) + k_2\phi_2'(x_0).$$

Hence (k_1, k_2) is a solution of the system of equations (3a, b). But this system of equations has a unique pair of solutions. Therefore $k_1=C_1$, $k_2=C_2$, and $g(x)=f(x)$ for all x in $I\cap J$.

Instead of starting with the existence assumption that a pair of solutions (ϕ_1, ϕ_2) such that $W(\phi_1, \phi_2)\neq 0$ exists, we could start with the assumption: Given a number $x=x_0$, for each pair of numbers (a, b) (or for at least two pairs (a_1, b_1) and (a_2, b_2) such that $a_1b_2\neq b_1a_2$) there exists a twice differentiable function $f_{a,b}$ defined on some neighborhood $N_{a,b}(x_0)$ of x_0 which is a solution to the differential equation on $N_{a,b}(x_0)$ such that $f_{a,b}(x_0)=a$ and $f'_{a,b}(x_0)=b$. (Such an assumption seems "natural" in many applications of differential equations in which empirical evidence leads us to believe that there is a solution to our "mathematical model" but we are concerned with the question: Have we imposed enough conditions in our model to ensure a unique solution?) If we take $\phi_1=f_{1,0}$ and $\phi_2=f_{0,1}$, then $W(\phi_1, \phi_2; x_0)=1$. Since $W(\phi_1, \phi_2)$ is continuous it will be different from zero in some neighborhood $N(x_0)$ of x_0 contained in both $N_{1,0}(x_0)$ and $N_{0,1}(x_0)$. We may then take $N(x_0)$ as the interval I of Theorems 1 and 2.

Notes. These results evolved from a conversation with Professor Beryl Clotfelter of the Grinnell College physics department concerning how to present efficiently a few rudiments of linear differential equations to a freshman physics class. I first observed that if f is a solution of $y' - ay = 0$ and we set $u(x)=f(x)/\exp(ax)$, then

$$\begin{aligned} u'(x) &= [\exp(ax)f'(x) - a\exp(ax)f(x)]/\exp(2ax) \\ &= [f'(x) - af(x)]/\exp(ax) = 0 \qquad \text{for all } x. \end{aligned}$$

Hence $u(x)=$constant and $f(x)=$(constant) $\exp(ax)$. Then noting that these calculations closely resemble the method of variation of parameters, I worked out the results given above.

Most textbooks on differential equations which I have examined either do not establish uniqueness or else establish uniqueness and existence simultaneously by means of the Picard theory. One textbook, *An introduction to ordinary differential equations* by Earl A. Coddington, Prentice Hall, 1961, pp. 56–58, establishes uniqueness prior to taking up the Picard theory by first proving the theorem: *if ϕ is a solution of $y''+ay'+by=0$ on an interval I containing the point x_0, then for all x in I:*

$$\|\phi(x_0)\|\exp(-k\,|\,x-x_0\,|\,) \leqq \|\phi(x)\| \leqq \|\phi(x_0)\|\exp(k\,|\,x-x_0\,|\,),$$

where $\|\phi(x)\| = ((\phi(x))^2+(\phi'(x))^2)^{1/2}$ *and* $k=1+|\,a\,|+|\,b\,|$. (He also extends this later to higher order equations and to equations with variable coefficients.)

In *Calculus with analytic geometry*, R. E. Johnson and F. L. Kiokemeister, Allyn and Bacon, 2nd ed., 1960, pp. 639–640, uniqueness is established for second order equations with constant coefficients by first proving that if f is a solution of $y''-ky$ (k a constant) on some interval, then f is analytic on that interval.

UNIQUENESS OF MEASURES

J. B. ROBERTSON, Cornell University

Let $\mathfrak{A}$ be a collection of subsets of a set X, and let $\sigma(\mathfrak{A})$ denote the smallest σ-ring containing $\mathfrak{A}$. Throughout this paper μ and ν will denote two finite measures on $\sigma(\mathfrak{A})$ which agree on $\mathfrak{A}$, i.e. $\mu(A)=\nu(A)$ for all A in $\mathfrak{A}$. In this paper we give some sufficient conditions on the structure of $\mathfrak{A}$ to insure that μ and ν must also agree on $\sigma(\mathfrak{A})$. It is well known that if $\mathfrak{A}$ is a semi-ring (i.e. $\mathfrak{A}$ is closed under finite intersections and the difference of any two sets in $\mathfrak{A}$ is the finite disjoint union of sets in $\mathfrak{A}$) then μ and ν must agree on $\sigma(\mathfrak{A})$ (cf. [1] sec. 13, prob. 4). (Notice that this is a slightly more general concept than that of a semiring as defined in [1], but the proof of the uniqueness of measures is the same in either case.) A special case of a semiring is a collection of sets which is closed under finite intersections and differences. It is also known (cf. [1] sec. 5, prob. 2) that if $\mathfrak{A}$ is a lattice (i.e. $\mathfrak{A}$ is closed under finite intersections and finite unions) then μ and ν must agree on $\sigma(\mathfrak{A})$. Halmos (cf. [1] sec. 13, prob. 3) has given, however, an example of a class of sets $\mathfrak{A}$, which happens to be closed under complements, and of two finite measures which agree on $\mathfrak{A}$ but not on $\sigma(\mathfrak{A})$. We shall prove:

THEOREM. *Let $\mathfrak{A}$ be a collection of subsets of X and let μ and ν be two finite measures on $\sigma(\mathfrak{A})$ which agree on $\mathfrak{A}$.*

(a) *If $\mathfrak{A}$ is closed under finite intersections, then μ and ν agree on $\sigma(\mathfrak{A})$.*

(b) *If $\mathfrak{A}$ is closed under finite unions, then μ and ν agree on $\sigma(\mathfrak{A})$.*

(c) *If $\mathfrak{A}$ is closed under differences, then μ and ν agree on $\sigma(\mathfrak{A})$.*

(d) *If $\mathfrak{A}$ is closed under symmetric differences, then μ and ν agree on $\sigma(\mathfrak{A})$.*

Proof (a). The following two formulas may be established by induction.

$$(1)\qquad \mu(A(1)\cup\cdots\cup A(n)) = -\sum_{k=1}^{n}(-1)^k\sum\mu(A(i_1)\cap\cdots\cap A(i_k)),$$

$$(2)\qquad \mu(A(1)\cap\cdots\cap A(n)) = -\sum_{k=1}^{n}(-1)^k\sum\mu(A(i_1)\cup\cdots\cup A(i_k)),$$

where the second summations in the two equations extend over all $(i_1, \cdots, i_k)$ such that $1\leqq i_1<\cdots<i_k\leqq n$. The same equations, of course, hold with μ replaced by ν. Formula (1) yields the result that if $\mathfrak{A}$ is closed under intersections and if μ and ν agree on $\mathfrak{A}$, then they must also agree on the set of all finite unions of sets in $\mathfrak{A}$, and formula (2) yields the same statement with unions and intersections interchanged. Thus if we define $\mathfrak{A}_n$ inductively by $\mathfrak{A}_0=\mathfrak{A}$, $\mathfrak{A}_{2n+1}$ = the set of all finite unions of sets in $\mathfrak{A}_{2n}$, and $\mathfrak{A}_{2n+2}$ = the set of all finite intersections of sets in $\mathfrak{A}_{2n+1}$, then $\mathfrak{A}_n\subseteq\mathfrak{A}_{n+1}$, $\mathfrak{A}_{2n}$ is closed under intersections, $\mathfrak{A}_{2n+1}$ is closed under unions, and, by induction, μ and ν agree on $\mathfrak{A}_n$. Now let $\mathfrak{A}_\infty=\bigcup_n\mathfrak{A}_n$. Clearly we have $\sigma(\mathfrak{A}_\infty)=\sigma(\mathfrak{A})$, μ and ν agree on $\mathfrak{A}_\infty$, and $\mathfrak{A}_\infty$ is a lattice. Thus, by known results, μ and ν agree on $\sigma(\mathfrak{A})$.

(b) Let $\mathfrak{B}$ be the collection of all finite intersections of sets in $\mathfrak{A}$. Clearly $\sigma(\mathfrak{A})=\sigma(\mathfrak{B})$ and by (2) μ and ν agree on $\mathfrak{B}$. Thus by (a) μ and ν agree on $\sigma(\mathfrak{A})$.

(c) $\mathfrak{A}$ is in fact a semiring: $A\cap B=A-(A-B)$. Thus (c) follows from known results.

(d) As in the proof of (b) it is sufficient to show that μ and ν agree on all sets which are finite intersections of sets in $\mathfrak{A}$. Let $A(1), \cdots, A(n)$ be sets in $\mathfrak{A}$. Let Y be the set of all n-tuples $(i_1, \cdots, i_n)$ such that for all $j=1, \cdots, n$, $i_j=0$ or 1 but not all of the i_j's are 1. Y has 2^n-1 points. For $(i_1, \cdots, i_n)$ in Y let

$$A(i_1, \cdots, i_n) = \Big(\bigcap_{\{j:i_j=0\}} A(j)\Big)\cap\Big(\bigcap_{\{k:i_k=1\}} A(k)'\Big).$$

(A' denotes the complement of A.) $A(i_1, \cdots, i_n)$ is either empty or an atom of the finite ring generated by $\{A(1), \cdots, A(n)\}$. Let $\mu(i_1, \cdots, i_n)=\mu(A(i_1, \cdots, i_n))$ and $\nu(i_1, \cdots, i_n)=\nu(A(i_1, \cdots, i_n))$. It is now sufficient to show that $\mu(i_1, \cdots, i_n)=\nu(i_1, \cdots, i_n)$ for all $(i_1, \cdots, i_n)$ in Y. Let $B(k)=\{(i_1, \cdots, i_n)$ in $Y: i_k=1\}$. If A is any finite set, $|A|$ will denote the number of points in A.

LEMMA 1. *Let* $1\leqq n_1<\cdots<n_r\leqq n$, $1\leqq m_1<\cdots<m_s\leqq n$, *and suppose that* $(n_1, \cdots, n_r)\neq(m_1, \cdots, m_s)$. *Then*:

(a) $|B(n_1)\Delta\cdots\Delta B(n_r)|=2^{n-1}$,

(b) $|(B(n_1)\Delta\cdots\Delta B(n_r))\cap(B(m_1)\Delta\cdots\Delta B(m_s))|=2^{n-2}$.

Proof of Lemma 1. (a) By renumbering we may suppose that $n_k=k$ for $k=1, \cdots, r$. As may easily be seen by induction, a point x is in $B(1)\Delta\cdots\Delta B(r)$ if and only if the number of $B(i)$'s, $i=1, \cdots, r$, which contain x is odd. Thus

the number of points in $B(1)\Delta \cdots \Delta B(r)$ is the number of points $(i_1, \cdots, i_n)$ such that for some k there are exactly $2k+1$ 0's in $(i_1, \cdots, i_r)$. Since there are 2^{n-r} points in Y with the first r places fixed and not all ones, there are $\binom{r}{k}2^{n-r}$ points with exactly k 0's in the first r places. Thus

$$|B(1)\Delta \cdots \Delta B(r)| = \sum_{k \text{ odd}} \binom{r}{k} 2^{n-r}.$$

$$\sum_{k \text{ odd}} \binom{r}{k} = \sum_{k \text{ even}} \binom{r}{k} = 2^{r-1}$$

as can easily be seen by induction using the relation

$$\binom{r}{k} = \binom{r-1}{k-1} + \binom{r-1}{k}.$$

Thus $|B(1)\Delta \cdots \Delta B(r)| = 2^{r-1}2^{n-r} = 2^{n-1}$ as desired.

(b) Again we may suppose that $n_k = k$ and also that $m_k = t+k$ for $t \geqq 1$. We may also assume that $s \leqq r \leqq s+t$. Thus $\min(r-t, 0)$ is the number of sets $\{B(n_1), \cdots, B(n_r)\}$ and $\{B(m_1), \cdots, B(m_s)\}$ have in common. Suppose first that $t < r < s+t$. As in the proof of part (a) of this lemma it is easy to see that $(i_1, \cdots, i_n)$ is in $(B(1)\Delta \cdots \Delta B(r)) \cap (B(t+1)\Delta \cdots \Delta B(t+s))$ if and only if for some k there are exactly k 0's in $(i_{t+1}, \cdots, i_r)$ and if k is even (odd), there are an odd (even) number of 0's in $(i_1, \cdots, i_t)$ and in $(i_{r+1}, \cdots, i_{t+s})$. Thus

$$|(B(1)\Delta \cdots \Delta B(r)) \cap (B(t+1)\Delta \cdots \Delta B(t+s))|$$

$$= 2^{n-s-t} \sum_{k=0}^{r-t} \binom{r-t}{k} \sum \binom{t}{i} \binom{s+t-r}{j}$$

where the second summation is over all odd i and j if k is even and over all even i and j if k is odd. Thus $|(B(1)\Delta \cdots \Delta B(r)) \cap (B(t+1)\Delta \cdots \Delta B(t+s))| = 2^{n-s-t}2^{r-t}2^{t-1}2^{s+t-r-1} = 2^{n-2}$ as desired. The special case when $s+t \leqq r$ is treated in a similar manner and yields the equation:

$$|(B(1)\Delta \cdots \Delta B(r)) \cap (B(t+1)\Delta \cdots \Delta B(t+s))|$$

$$= 2^{n-r} \sum_{i \text{ odd}} \binom{s}{i} \sum_{j \text{ even}} \binom{r-s}{j} = 2^{n-r}2^{s-1}2^{r-s-1} = 2^{n-2}$$

as before. Similarly, if $r \leqq t$, we obtain

$$|(B(1)\Delta \cdots \Delta B(r)) \cap (B(t+1)\Delta \cdots \Delta B(t+s))|$$

$$= 2^{n-r-s} \sum_{i \text{ odd}} \binom{r}{i} \sum_{j \text{ odd}} \binom{s}{j} = 2^{n-r-s}2^{r-1}2^{s-1} = 2^{n-2}$$

which completes the proof of the lemma.

Since μ is a measure, we have the equations

$$\sum \mu(i_1, \cdots, i_n) = \mu(A(n_1)\Delta \cdots \Delta A(n_k)), \tag{3}$$

where the summation is over all $(i_1, \cdots, i_n)$ in $B(n_1)\Delta \cdots \Delta B(n_k)$. Now think of the $\mu(i_1, \cdots, i_n)$'s as 2^n-1 unknowns. (3) is then a system of 2^n-1 equations (one equation for each distinct $B(n_1)\Delta \cdots \Delta B(n_k)$) with 2^n-1 unknowns. Let M denote the 2^n-1 by 2^n-1 matrix whose elements are the coefficients of the $\mu(i_1, \cdots, i_n)$'s in (3), and let $\mathfrak{y}$ and $\mathfrak{v}$ be the 2^n-1 dimensional vectors whose components (in some order) are the $\mu(i_1, \cdots, i_n)$'s and the $\nu(i_1, \cdots, i_n)$'s respectively. On replacing μ by ν in (3) we get the same system of equations since, by hypothesis $\mu(A(n_1)\Delta \cdots \Delta A(n_k)) = \nu(A(n_1)\Delta \cdots \Delta A(n_k))$. Thus we have the vector equation $\mathfrak{y}M = \mathfrak{v}M$. Therefore we shall have the desired result, namely that $\mu(i_1, \cdots, i_n) = \nu(i_1, \cdots, i_n)$ for all $(i_1, \cdots, i_n)$ in Y, if we can show that $\det M \neq 0$. M is a matrix of 0's and 1's and Lemma 1 tells us that the diagonal elements of MM^t (where M^t denotes the transpose of M) are all equal to 2^{n-1} and every other element is equal to 2^{n-2}. Let M_k be the $k \times k$ matrix with 2's in the diagonal elements and 1's everywhere else. Then

$$(\det M)^2 = (2^{n-2})^{2^n-1} \det M_{2^n-1}. \tag{4}$$

LEMMA 2. $\det M_k = k+1$.

Proof of Lemma 2. The proof is by induction on k. For $k=1$, M_k is just the number 2 and so the lemma is true. Suppose the lemma is true for k. On subtracting the second row of M_{k+1} from its first row and expanding the new determinant by cofactors of its first row, we obtain

$$\det M_{k+1} = \det M_k + \det N_k, \tag{5}$$

where N_k is a $k \times k$ matrix in which every diagonal element except the first is equal to 2 and every other element is equal to 1. On subtracting the second row of N_k from its first row and then expanding the new determinant in cofactors of its first row, we find that $\det N_k = \det N_{k-1}$. Since $\det N_1 = 1$, $\det N_k = 1$ for all k, and hence (5) gives the desired result.

Lemma 2 and equation (4) imply that $\det M \neq 0$ and, in turn, completes the proof of the theorem.

We remark that by a standard measure-theoretic argument the theorem remains true if instead of supposing that μ and ν are finite measures on $\sigma(\mathfrak{A})$, we suppose only that μ and ν are measures on $\sigma(\mathfrak{A})$ which are σ-finite on $\mathfrak{A}$. That some such finiteness conditions must be imposed on the values of the measures on $\mathfrak{A}$, as opposed to $\sigma(\mathfrak{A})$, is shown in [1], sec. 13, prob. 5.

This research was supported by the Office of Naval Research under grant No. WR-401(50) with Cornell University.

A PROOF OF THE CAUCHY INTEGRAL THEOREM

FR. A. O. KONNULLY, St. Albert's College, Ernakulom, Kerala (India)

If $f(L)$ is analytic within, and continuous on, a simple closed curve C, then $\int_C f(z)dz=0$. The following proof of this theorem is a modification of my earlier argument [1].

It is assumed that the curve C is continuous and rectifiable and that it has a finite number of maxima and minima, that is, it can be divided into a finite number of parts, say N parts, on each of which each of the coordinates is either increasing, decreasing or constant.

From the given conditions we have:

(i) To a given $\epsilon>0$ there corresponds an η such that $|f(z)-f(z')|<\epsilon$ if $|z-z'|<\eta$, η being independent of the positions of z and z' inside or on C. (Uniform continuity.)

(ii) If C' be a closed curve lying entirely within the region bounded by C, to a given $\epsilon'>0$ there corresponds an η' such that

$$\left|\frac{f(z)-f(z')}{z-z'}-f'(z)\right|<\epsilon',$$

if $|z-z'|<\eta'$, η' being independent of the positions of z and z' inside or on C', (Goursat's Lemma).

(iii) LEMMA. *If Γ be a closed curve lying entirely within C, then*

$$\int_\Gamma [f(z)+zf'(z)]dz=0.$$

To prove this, let g be the greatest distance of the origin from C and γ be the length of the curve Γ. Then

$$\begin{aligned}\int_\Gamma f(z)dz &= \lim \sum f(z_i)(z_i-z_{i-1}), \qquad \text{points } z_i \text{ being on } \Gamma,\\ &= \lim \sum z_i[f(z_i)-f(z_{i+1})]\\ &= \lim \sum -z_i[f'(z_i)+\epsilon_i](z_{i+1}-z_i)\\ &= -\int_\Gamma zf'(z)dz, \qquad \text{since } \lim \sum \epsilon_i z_i(z_{i+1}-z_i)=0,\ |\epsilon_i z_i(z_{i+1}-z_i)|\end{aligned}$$

being ultimately less than $\epsilon' g\gamma$ by (ii).

Proof. First we prove the theorem for a curve C enclosing a region within which we can find a point O such that any radius vector from O meets the curve in a single point. We take such a point within C as origin.

$$\int_C f(z)dz=\lim \sum f(z_i)(z_i-z_{i-1}).$$

Let $I(t)$ denote $\lim \sum f(tz_i)t(z_i-z_{i-1})$, where z_i are points on C. If C_t denotes the curve traced by the point tz as z moves on C, $0<t<1$, then $I(t)=\int_{C_t} f(z)dz$. If $0<\delta<\frac{1}{2}$, then $C_{1-\delta}$ is a curve lying entirely within the region bounded by C.

Now,

$$\frac{d}{dt}\lim \sum f(tz_i)t(z_i - z_{i-1}) = \lim \sum \frac{d}{dt} f(tz_i)t(z_i - z_{i-1}), \qquad (0 < t \leqq 1 - \delta)$$

since

$$\left|\frac{I(t+h) - I(t)}{h} - \lim \sum [f(tz_i) + tz_i f'(tz_i)](z_i - z_{i-1})\right|$$

$$= \lim \left| \sum \left[\frac{f(\overline{t+h}\, z_i) - f(tz_i)}{z_i h} - f'(tz_i)\right] tz_i(z_i - z_{i-1}) \right.$$

$$\left. + \sum [f(\overline{t+h}\, z_i) - f(tz_i)](z_i - z_{i-1}) \right| \leqq \epsilon' gL + \epsilon L,$$

for $h<1/g \min(\eta, \eta')$, by (i) and by (ii) with $C'=C_{1-\delta}$, L being the length of the curve C.

Thus

$$\frac{d}{dt} I(t) = \lim \sum [f(tz_i) + tz_i f'(tz_i)](z_i - z_{i-1})$$

$$= 1/t \int_{C_t} [f(z) + zf'(z)]dz = 0 \quad \text{by (iii).}$$

Therefore

$$I(1-\delta) - I(\delta) = \int_{\eta}^{1-\delta} \frac{d}{dt} I(t)dt = 0$$

so that we have $I(1)=I(1)-I(1-\delta)+I(\delta)$. Let δ tend to 0. Then $I(\delta)$ tends to 0. Also $I(1)-I(1-\delta)$ tends to 0, since, when δ is small enough,

$$\left| \sum |f(z_i) - f(\overline{1-\delta}\, z_i)|(z_i - z_{i-1}) \right| < \epsilon L$$

by (i) and therefore

$$|I(1) - I(1-\delta)| = \lim \left| \sum [f(z_i) - f(\overline{1-\delta}\, z_i)](z_i - z_{i-1}) \right.$$

$$\left. + \delta \sum f(\overline{1-\delta}\, z_i)(z_i - z_{i-1}) \right|$$

can be made arbitrarily small. Hence $I(1) = \int_C f(z)dz = 0$.

Next, suppose that C is a curve enclosing any region D. Divide D by lines drawn parallel to the x-axis and y-axis, partially into regular subregions which are squares and partially into irregular subregions which are portions of squares

of which the remaining part lies beyond C. Then the integral $\int f(z)dz$ taken in the same sense along the boundary of each of these subregions is equal to the integral $\int f(z)dz$ along the complete boundary C. (For, each portion of the transversals separates two contiguous regions and is described twice in integration in opposite senses, so that when these integrals are added there will remain only the integrals taken along the curve C whose sum is the integral $\int_C f(z)dz$.) And, by what has been proved above, the integral taken round each of the regular subregions is zero, since $f(z)$ is analytic within and continuous on the boundary of any such region which, being a square, has always an interior point such that any radius vector from it meets the boundary in a single point. Thus $\int_C f(z)dz$ is equal to the sum of the integrals $\int f(z)dz$ taken round the irregular subregions.

Let c_k be the boundary of any of the irregular subregions and s_k be its length. If h_k be the length of the side of the square of which the irregular subregion is a portion and b_k be the length of the arc of C which forms a part of c_k, then $s_k \leqq (4h_k+b_k)$. And any two points of the region bounded by c_k will be apart by a distance not exceeding $\sqrt{2}h_k$.

Given $\epsilon>0$, the parallels may be so chosen that each $h_k<\eta/\sqrt{2}$. Then by (i), for any point z on c_k and a fixed point a_k on or within c_k we have $|f(z)-f(a_k)| \leqq \epsilon$. Thus,

$$\left| \int_{c_k} f(z)dz - \int_{c_k} f(a_k)dz \right| = \left| \int_{c_k} [f(z) - f(a_k)]dz \right| \leqq \epsilon s_k.$$

That is, $|\int_{c_k} f(z)dz| \leqq \epsilon s_k$, since $\int_{c_k} f(a_k)dz = f(a_k)\int_{c_k} dz = 0$.

Thus we have $|\int_C f(z)dz| = |\sum_k \int_{c_k} f(z)dz| \leqq \epsilon(\sum_k s_k)$, where $\sum_k$ denotes summation over all irregular subregions arising from the division of D into smaller parts by the parallels chosen when ϵ is given. And $\sum_k s_k \leqq \sum_k (4h_k+b_k) \leqq 2N(P+L)$, where P is the perimeter of a square with sides parallel to the co-ordinate axes which would contain within it the entire region D. For, the boundary c_k of each subregion has an arc of C (of length b_k) to form a part of it which belongs to it exclusively. And if we take all the boundaries whose arcs go to make up each one of the N parts of C on which each of the co-ordinates is either increasing or decreasing or constant, then the sides h_k of the corresponding squares for each part of C, the side of any square with arc b_k belonging partly to more than one part of C, such as the squares which contain a vertex (the junction of two of the N parts), being counted once in connection with each part of C, will add up to not more than two of the sides of the square containing D (all the transversals dividing D into subregions being supposed to lie in it); so that we have $\sum 4h_k \leqq 2NP$. Thus $|\int_C f(z)dz| \leqq \epsilon 2N(P+L)$. Since ϵ is arbitrary, it follows that $\int_C f(z)dz = 0$.

MODERNIZATION OF SCHOOL MATHEMATICS IN HOLLAND

W. J. BRANDENBURG, Groningen University, Holland

In Holland a reorientation of grammar school teachers in mathematics by means of courses has begun.

Four courses were given so far, the first one in September 1963 and the last one in September 1965. Each course took five days. They were given at the universities at Utrecht and Groningen and at the Technical University at Eindhoven.

In principle the content was independent of modernization, if any, of the curriculum. In all places mentioned the same subjects were treated. The subjects were: set theory; logics and linear algebra; linear analysis; topology and group theoretical aspects of elementary geometry. The courses consist of lectures and practical exercises. The lectures were generally given by professors. For practical exercises assistance was given by members of the scientific staff. For the exercises the students were divided into groups. The courses were free of charge for the participators. Hotel and travelling expenses were borne by the State. Each course was followed by about 525 grammar school teachers, i.e., about 50 percent of the number of competent mathematics teachers in this country.

Further it is important that between the courses these teachers have been working in study groups at the execution of projects resulting from these courses. At the moment two school-projects are being executed: a geometry project and an algebraic analysis project. For the geometry project a text has been made by Troelstra and Kuipers for a new treatment, based on modern insight, of geometry in the first form. The experiments were verified and coordinated by the Committee. Twelve grammar schools participate in the geometry project.

The continuation of this project for the second forms of the schools mentioned is being prepared. The concept of "representation" is put in a central place in geometry. Those who want to orient themselves somewhat can best consult *Transformatie Meetkunde* (Transformation Geometry) 1, 2 and 3 by Troelstra, Habermann, De Groot and Bulens.

The algebra project is executed at seven schools.

The project is executed in the superior forms of secondary schools and gymnasiums, consequently in the 4th and 5th forms and in the 5th and 6th forms respectively. These schools will hold a separate final examination for these subjects of instruction.

Apart from this also discussions take place about teaching analytical geometry, especially with regard to introduction of vectors.

At Groningen a course in modern algebra is given for secondary school teachers from the three Northern provinces. This course has an annex at Leeuwarden. It has been organized by the Stichting voor Pedagogisch Onderwijs aan de Rijksuniversiteit te Groningen (Foundation for Pedagogical Teaching at the State University at Groningen). The supervision has been entrusted to Gerretsen, member of the Curriculum for Mathematics. As text book was used: John L. Kelley, Introduction to Modern Algebra, New York.

During twenty weeks (ten before and ten after Christmas holidays) two hours a week, on Thursdays from 4:30 to 6:15 p.m., were devoted to teaching. In the first hour a lecture is given for all students together and in the second hour work is done by groups of twenty under the guidance of instructors. There are 120 students and consequently six groups. There are two groups at Leeuwarden and four at Groningen. The instructors are also always present at the first weekly lecture. The course may also be followed by advanced technical school teachers.

The subjects "Axioms for Numbers" and "Sets and Numbers" were treated in five afternoons. "Vectors and Lines" and "Inner Products" were treated in six afternoons. "The Complex Plane" and "Vector Geometry" were taught in seven afternoons. "Matrix Algebra" took two afternoons. The course was taught by W. J. Brandenburg.

The lecturers and instructors drew up a report about each lecture by means of a form containing various categories. This procedure resulted in a report.

In order to ascertain the result of the last mentioned course the pupils of the instructed teachers have been tested. During this test the pupils were examined with regard to their knowledge of the concept "intersection" and their skill in using it.

In the course of this examination on a very moderate scale three equal tests were applied, each dealing with different teachers and different pupils:

I—A pretest, before the teachers had acquainted themselves with the concept "intersection."

I. PRETEST

5 teachers	number of pupils	number of correct items
form	*N*	*score*
1	71	5
2	57	1
3	—	—
4	36	2.5
total	164	8.5

Number of good items per pupil: 0,05 on the average

II. TEST

22 teachers *form*	*N*	*score*
1	24	20
2	32	10
3	32	15.5
4	28	23.5
LTS*	6	3.5
	122	72.5

Number of good items per pupil: 0.6 on the average
* Primary Technical School

III. POSTTEST

10 teachers *form*	*N*	*score*
1	10	3
2	19	8
3	13	2
4	10	0
UTS**	6	0.5
	58	13.5

Number of good items per pupil: 0.24 on the average
** Secondary Technical School

II—A test, some weeks after the teachers had been introduced to the concept "intersection."

III—A posttest, after the course had ended all but for the last lesson.

The concept "intersection" was taken because modernization of school teaching generally begins by introducing "sets" and "operations of sets." The operation which is most often necessary in our school teaching of mathematics is the determination of the intersection of two sets.

The outcome of test I being 0.05 items correct on the average per pupil indicates that without instruction given to the teachers the pupils are not acquainted yet with the concept "intersection" without their school.

The outcome of test II being 0.6 items correct on the average per pupil indicates that some weeks after the instruction given to the teachers the concept "intersection" had not yet been dealt with in their teaching.

The outcome of test III being 0.24 items correct on the average per pupil indicates that immediately after the end of the course it does not influence the teaching of mathematics in schools to such an extent that the pupils are already acquainted with the concept "intersection."

Next year a second course will be organized on the same lines but then about geometry based on linear algebra. As regards some concepts the second course

will continue the first one. Out of the 120 participators 115 have already expressed their willingness to follow the second course too.

The members of the course have been working hard as could be concluded quite well from the exercises.

The course in modern algebra will be repeated on the same lines in four other places this year.

For advanced elementary education an instruction project will be prepared.

In the years to come some influence may perhaps be recorded. The question arises whether one should stimulate this without anything more. Actually we have to conclude that it is a too optimistic idea to modernize the teaching of mathematics only by instructing teachers in modern mathematics.

The instruction should at least be followed by

1. a pedagogical working up of modern mathematics into subject matter of teaching; and
2. a project in which this subject matter is tested in schools in a way that meets the requirements of educational research.

NATIONAL ASPECTS OF THE MAA-SA CONTEST IN THE DEVELOPMENT OF TALENT

NURA D. TURNER, State University of New York at Albany

This paper is relative to a study I have been conducting for eight years on the academic and professional progress of 117 students (on 14 of these I have incomplete information with respect to fields of preparation and degrees) who ranked in the top one percent in the Upstate New York Section of the MAA in the 1958–60 Contests and a group of students who ranked in the top .03 percent nationally in the 1958 Contest. The title listed implies not only the identification of high ranking students but furthering the counselling, guiding, and encouraging of these mathematically talented students. The work covered by this paper does not include the latter implication; it has to do only with a follow-up study of the group defined but does include the effect a mathematical background has had on the chosen careers of the group, a glance at home backgrounds, and recommendations to the MAA for post-contest study.

Students in the study come from a cross section of typically American families. Among their parents are farmers, ministers of the gospel, machine shop workers, warehouse foremen, secondary school teachers, college professors, administrators, carpenters, and medical doctors; some parents have not had as much as a high school training; some have college degrees. They are products of the opportunity that the USA provides to all. At least one student, who is a promising medical doctor, illustrates this advantage that living in the USA provides. His grandparents came here as immigrants. Two were illiterate. One grandfather had a push cart, later a store; but his father had eleven years of schooling and eventually became a district sales manager and his mother graduated from high school and is a secretary.

The Contest has properly identified these students as talented in mathematics. The majority of the students have received scholarships on both the undergraduate and graduate levels. Many have either borrowed money or worked during the summer to supplement scholarship aid. The average grade of college work, when the average has been taken over all subjects, is a B+.

The subject matter field attracting the greatest number of students has been mathematics. Related fields have attracted a majority of the students. The chart on the following page shows the frequency of fields to which students have been attracted and the degrees which they have obtained or are seeking. Some students are still in the academic atmosphere working on doctorates, master's degrees and even bachelor's degrees; some are in medical residencies; some are farming; some are teaching on the college or university level; some are practicing law; some are training for a religious life; some are working on staffs of commercial airplane companies, in defense work related to the Gemini, Saturn, and Apollo projects as well as work related to air force weapons, working for oil companies, for retail credit companies, for accounting firms; some are doing army duty; and some are homemakers.

No one is teaching in the secondary school. Of the five who completed certification requirements for secondary teaching, one feels he might consider the field; two had a taste and quickly left; a fourth is working in a YMCA; and the fifth said, "I always loved mathematics—couldn't say the same for teaching—couldn't stand the placid acceptance of mediocrity among most of my prospective colleagues."

Throughout the range of the careers into which these students have gone, or plan to go, from architecture to biomedical engineering, to linguistics, to medicine, to teaching at the college level, there is a recognition of the helpful effect of mathematics. Some illustrations will suffice.

An architectural student states: "In the technical courses in architecture school (acoustics, structures, heating and air-conditioning) students with strong mathematics background find a functional understanding much easier. Too many structures students give up at the sign of an integral."

A young accountant emphasizes that "many in the accounting profession, public and private, have not yet understood the applicability of mathematical approaches using statistical methods and mathematical models."

An aeronautical engineer who will obtain his doctorate in September feels he is ending up being more of a mathematician. Once he realized that most engineers know "far too little mathematics" and that those in charge of the engineers "know a lot more," most of the courses he took from then on were "disguised mathematics" courses. Now he feels well prepared to solve problems that are presently unsolvable simply because those who have attempted solutions have not known enough mathematical techniques.

A biomedical engineering student expecting a doctorate in 1967 has been applying mathematics, particularly control system theory, "to the study of physiological systems, i.e. circulatory systems, respiratory systems, etc. so that

Field of Study	Degree

* One a dropout who has never returned; another who has applied for admission to an engineering school.

they may be investigated in a more formal, quantitative way."

One law student explains that mathematics courses have had little direct relationship to his law studies but that the study of mathematics has helped him to develop a crisp analytical approach to legal problems. He states: "My free-lance study of symbolic logic (Copi, Quine) has been of direct use in law school; a logical formation of the problem is not a solution, but certainly is a healthy start."

Two other law students, one an attorney in the Tax Division, Department of Justice, the other Legal Counsel, Office of National Planning, Government of Liberia, stress the importance of a mathematical background. One feels it has helped develop his powers of analysis and the other that the development of such powers may have contributed to his great success in law school.

A doctoral candidate in linguistics is glad to have learned what mathematics he did because of its relevance to his field. "First, there is much computation in acoustic phonetics, which studies the duration and frequencies of the sounds of speech. Second, linguistics has the influence of probability and probabilistic thinking, especially in the related area of communication theory. More important, a strain of mathematical thinking runs through all linguistics; the entire field has been described as an effort to mathematize language."

A medical student who is doing his utmost to integrate his mathematical training with medicine has learned computer language on the side. For him it is "fascinating to even think that perhaps someday one may be able to program a computer to read X-rays."

These students have already published scholarly works. A list of known publications follows:

1. Earl B. Arnold, An Evaluation of an On-Line Computing System, Shell Development Technical Report, No. 298–65.
2. D. J. Benney and J. C. Luke, On the Interactions of Permanent Waves of Finite Amplitude, J. Math. and Phys., December, No. 4, 43 (1964) 309–313.
3. Howard A. Bodner, Active All-Pass Network, *Electronics Letters*, (London), Vol. 1, No. 4, June, 1965.
4. G. J. Grayson, and W. J. Kuhns, Hemolytic Factors Affecting the Survival of Transfused Cadaver Blood, (an abstract), *Transfusion*, September-October, No. 5, 3 (1963) 433.
5. J. C. Luke, A Perturbation Method for Non-Linear Dispersive Wave Problems, Proc. Roy. Soc. A, No. 430, May 31, 292 (1966) 403–413.
6. Alan Zame, A Combinatorial Word Problem, this MONTHLY, May, 70 (1963) 531–539.

Carl E. Baum has published 4 classified technical reports, 22 papers (one classified) for a restricted distribution list, and has contributed to 2 large summary type documents (classified). All these deal with nuclear weapons effects and instrumentation.

Three articles by Krohn Mateosian, and Rhodes are to be published: "Methods of the Algebraic Theory of Machines, I" in the *Journal of Computer and System Sciences;* "Complexity of Ideals in Finite Semigroups and Finite State Machines," in *Journal of Mathematical Systems Theory;* and "Lectures on Algebraic Theory of Finite Semigroups and Finite State Machines," in *Procedures of Conference on Algebraic Theory of Machines, Languages, and Semigroups.*

So far what you have heard might have been expected. What I say now you may or may not have expected.

Among the students making mathematics and physics their careers, 32 in the doctoral category, there are many who feel the need for guidance particularly from mathematics teachers in high school and undergraduate college work.

One student who will begin an NSF post doctoral fellowship in mathematics this fall states, "If I had not had a certain amount of experience in advance (gained from reading an algebra book in the library while in the 8th grade), I think that I might have become confused and discouraged when algebra was first presented to me in the ninth grade. . . . My enjoyable experiences in mathematics have been almost entirely outside the classroom."

Another who is on his last lap of a doctorate in theoretical physics reveals, "When I was in elementary and high school, I was unaware of the existence of many important branches of mathematics in which I have since taken courses. I was also unaware of the extent of the importance of mathematics in modern science and engineering."

Still another who will obtain his doctorate in mathematics in January and who completed a four year high school mathematics sequence in two years and scored A grades in exemption examinations his junior year in college states, "At no time, even in special classes or in mathematics team practice sessions did

any teacher indicate what mathematicians do or what mathematics is all about. In my first two years of college, I was not enlightened further. As a junior, my mathematics adviser merely asked which courses I was interested in and signed her approval. Nonscience majors, on the other hand, were given an eye-opening introductory course in foundations of modern mathematics. As an upper junior, I registered for an advanced version of this course and finally learned what mathematicians call mathematics. I would say that the school system has wasted about ten years of my mathematical life."

The meaning of what is said by another student, who will receive a doctorate in mathematics in September, is veiled, but still evident. At first he thought in order to study mathematics one would have to become a physicist or an engineer and only later was surprised to discover that one could pursue a career studying pure mathematics.

A student now working toward a doctorate in sociology has this advice: "The need for better precollege guidance is critical. The student should not rely solely on parents or high school counselors, but should seek out more objective and experienced sources of information." Apparently, the young man has little respect for guidance counselors.

While wanting guidance and encouragement, there is indication that many students studying on the doctoral level resent and resist pressure to study mathematics.

A student working on a doctorate in sociology feels that encouraging any and all students to study mathematics just because it is such a good field represents "a somewhat unjustified academic imperialism." He would rather give students a clear picture of what each field is and can be, providing them with a background that will give them self-confidence, and let them decide what they want to do.

A student well on his way to becoming a medical doctor implies he objected to pressure when he said, "I received nothing but encouragement everywhere I turned. Too much, I'm afraid."

Others indicated an appreciation of a lack of pressure. A statement will suffice. "My family always encouraged me without, however, forcing me into any particular direction."

In general, students resent pressure. They want to be free to make the choice of a career, and they want a good introduction to the field of their choice.

About one-fourth of the students studying or working in mathematics or in related fields have lost interest to some extent in mathematics.

Of three on the doctoral level in mathematics, one has found the subject "too dry–emotionless" but the time too late for changing fields. A second, interested in linguistics, is following the advice of one of his professors that one can more easily be a professor of mathematics with a side interest in linguistics than vice versa. A third, studying for a doctorate, who had mathematical talent compared to those around her in high school, is finding, along with other girls in the graduate school where she is studying, that her interest in higher mathe-

matics is limited. She adds, "If I were less far along, I would consider a career in one of the social sciences—anthropology or psychology. I believe my mathematical background would be useful in these fields in terms of a rigor of thought and ability to state what a problem is. The existence of areas such as 'mathematical psychology' confirms my belief in the overlap of such areas."

Several continued with mathematics to a bachelor's degree and switched to another field on the graduate level. Pure mathematics was not the "cup of tea" for one student. While continuing to major in mathematics, he took courses stressing practical applications (e.g. numerical analysis, computer simulations). For another, pure mathematics became too abstract for his "less than rigorous personality"; he found "operations research as potentially a more attractive blend of quantitative techniques and practical applications." Both these young men obtained master's degrees in business administration. Another found that when he reached the "more advanced and theoretical courses, such as advanced calculus," he "did not enjoy them nearly as much as earlier courses." He switched to medicine. Still another found that most of advanced mathematics did not interest him as much as working with numbers. He decided to try actuarial work for a year. He has passed Part 8 of the actuarial examinations and must be in the work to stay. Two others switched to library science and political science.

The switch for others came after their contact with calculus or advanced calculus—some, good students on the 'A' level in mathematics. One felt that "mathematics was just a 'game', having little relevance to everyday life." He switched to English. For another student, mathematics courses at the level of advanced calculus did not hold his interest. "They seemed to be more and more a matter of theorem proof, theorem proof." He changed his major to physics, studied on the master's level, and then entered the field of computer programming.

Four students are known to have become so disinterested that they became dropouts. Three are making comebacks, however. One is well on his way to a bachelor's degree in accounting while working for an accounting firm; his interest in mathematics waned in his sophomore year but he now realizes its importance in the sophisticated direction in which accounting is turning. A second who left engineering, again in the sophomore year, has been working as an inspector for General Electric, attending night school, and has applied for admission to an engineering college. The third is back studying architecture after a checkered career. The fourth dropped out at the end of his sophomore year and returned to the farm where he is happy.

Improvement in mathematics instruction and counselling could help students to stay with mathematics and keep from floundering. Attention has been called to the change in interest in mathematics after introduction to calculus courses and to dropouts at about the time or after the time a student is introduced to such courses.

What a student who is working on a doctorate in mathematics says may

shed light on the situation. His reference is to a freshman honors course in calculus. "My mother, father, brother, and sister had each done very well in high school and each of them had fallen down when introduced to calculus in college. I was determined that the curtain wasn't going to descend on me as it had on them and fortunately I ran into one of the best teachers I have ever had. . . . He was very youthful and dynamic in the classroom and expected a great deal from his students. I have always felt very fortunate to have had him as a teacher in that course, especially as I have seen so many other students who have done poorly in freshman calculus principally because of lack of interest. The material is not dull at all—it is only that it is often presented in a noninteresting way. And I feel this course is the most important for a prospective student of mathematics; it occurs at the time he is deciding what field to enter."

What another student who is working on a doctorate in philosophy says may shed more light on the situation. His reference is to his freshman calculus course. He reached the point of "hating" mathematics. "A discouraging and unsuccessful bout with the calculus my freshman year helped to direct me away from the scientific and engineering fields. Whether I would have become interested in liberal arts and especially in philosophy if I had not conceived a dislike for mathematics is questionable. My course in Symbolic and Mathematical Logic (taught by a superb teacher) has just this year (first year of graduate work) reawakened my appreciation for and delight in mathematical thought. I wish now I had persevered in mathematical studies. My interest in mathematics (and my skill) were in problem solving and manipulation rather than theory which probably had a lot to do with my difficulties with the theoretical mathematics I took in college."

While one could not expect all students who have been identified as mathematically talented to pursue a career in pure mathematics, some of the students covered by this paper seem to have been literally driven out of mathematics. While students do not want to be pressured and indicate resistance to pressure to take mathematics, they also indicate that in the educational system there exists a lack of counselling, guidance, and encouragement to continue with mathematics.

The MAA-SA Contest has so far only identified mathematically talented students. The 1966 report of "The Seventeenth Annual H.S. Mathematics Contest" states the purpose as going no further than seeking to sharpen certain mathematical concepts and skills.

A great amount of money has been spent on this contest. From my experience as contest chairman in the Upstate New York Section, the total cost for administering the examination internationally, including cost of use of building facilities, cost of teacher time in preparing students and proctoring and grading the examination papers, and cost of section chairmen and national committee members time cannot be less than a half million dollars per year. One might consider that the buildings would still exist and the teachers would still be paid if the Contest were not held. But any business, industry, or organization evalu-

ates the cost of a project in terms of employee time and facilities used even though the employees would have been paid and the facilities kept up had the project not been undertaken. The expenditure of such a sum of money each year should result in more than mere identification of talent or sharpening of concepts and skills.

There are certain weaknesses in mathematics education. This paper has identified at least three of them.

1. There is a weakness in the area of introducing students to a general knowledge of what mathematics is about.

2. There is a weakness in mathematics counselling on both the secondary and college levels.

3. There is a weakness in teaching mathematics at the calculus level, both elementary and advanced. Too many mathematics students are turning to other fields at this point. Students have been frank in saying this has been where they have lost interest.

This evaluation of the results of the Annual High School Mathematics Contest involving, primarily, students in one section of the USA but, as well, a group of students on a national basis, points out definitively the need for strengthening the Contest program by using it as more than a tool merely for identification of talent and sharpening of skills. As in all good educational programs, it should be used as a tool to improve the educational process.

As a result of the evaluation contained in this paper, I recommend to the Mathematical Association of America that a committee be appointed for the purpose of finding ways in which the MAA can contribute to advising, guiding and encouraging mathematically talented students identified by the Annual High School Mathematics Contest and to investigate reasons for mathematics dropouts at the calculus level.

The opportunity of using this testing program as an educational tool is important enough to demand study and the thinking of several people.

International Congress of Mathematicians, Moscow, USSR, August 18, 1966.

MATHEMATICS IN NEPAL

T. J. LARDNER, Massachusetts Institute of Technology

I recently returned from Kathmandu, Nepal, where I spent the academic year 1965–1966 as a Fulbright Lecturer in Mathematics at Tribhuvan University. While in Nepal, I often thought of how trivial our problems in education are compared to those existing in underdeveloped countries such as Nepal. At times, one feels that to make a minor improvement in educational policy in such countries requires a major change in the economic and social structure of the country.

The purpose of this article is to acquaint the reader briefly with Nepal, its history, [1] and its system of education, especially in mathematics.

Nepal is a Hindu kingdom of a size approximately 100 miles by 500 miles, situated in the Himalayan region north of India and south of Tibet, and with a population of approximately 10 million people. In the east it is bordered by the Indian protectorate of Sikkim, and in the west by the state of Uttar Pradesh in India. Nepal is well-known as the birthplace of Buddha, for Mount Everest, and as the home of the Gurka soldiers. It contains a wider range of physical diversity than probably any other country of comparable size. The mountain mass of the Himalayas in the north contain some of the world's highest peaks, and to the south, less than 100 miles away, the cultivated fields and jungles of the northern rim of the Gangetic plain are 600 feet above sea level.

The country can be divided into three main geographic regions: the Mountain Region, which constitutes almost three-fourths of the total area; the Kathmandu Valley; and the Tarai Region, a narrow belt which extends along the boundary with India in the northern part of the Ganges River plain. Nepal is so mountainous and hilly, that, for example, a 35-minute flight by DC-3 from Kathmandu to Pokhra, a distance of 90 miles, takes 8 days by foot, the only other means of travel.

Kathmandu, the capital, is the center of almost all the cultural, educational and intellectual activity in Nepal, and the history of Nepal is often only the history of the valley of Kathmandu which contains, besides Kathmandu, the towns of Patan and Bhaktapur. The three towns came under a common king in 1769 when Prithvi Narayan Shah, the ruler of the Kingdom of Gorkha, conquered the valley and established the Shah Dynasty of which the present king, Mahendra Bir Bikram Shah Deva, is a member. However, in 1846, Jang Bahadur Rana became Premier, suppressed the authority of the king, and from 1846 to 1950 the Rana family ruled Nepal in a feudal manner. The country, during this time, was closed to foreign visitors with only a few exceptions.

There were no schools in Nepal when Jang Bahadur Rana became Premier, and an English tutor was engaged for his children in 1854. It was not until about 1880 that the first high school opened in Nepal, and this was restricted to children of the Rana family. Other than a few Sanskrit institutions in Kathmandu and some village literacy classes, there were no other schools in Nepal in the late nineteenth century.

A brief shift in government educational policy came in 1901 when Prime Minister Deva Shamsher Rana proposed the establishment of a system of universal public primary education. His plans were not successful, and only a few primary schools were opened. Before World War II, several new middle and high schools were founded in Patan and outside the valley, and a girls' high school was opened in Kathmandu.

In the early twentieth century, education beyond the high school level could be obtained only outside the country. As a consequence, less than a dozen Nepalese received higher academic or technical training during this period. Of these, most attended either Patna University or Benares Hindu University in India. In 1918 Prime Minister Chandra Shamsher Rana established a college

for Nepalese students in Kathmandu named Tri-Chandra College, which offered a two-year course in history, mathematics, logic, and languages. In 1919, science was added, and in 1924 with an enrollment of thirty, it became a full four-year institution, the first college in Nepal. It remained affiliated with Patna University until the establishment of the national university in Nepal in 1959.

After World War II, more or less forced to do so by the example of growing educational facilities in China and India, the Ranas made a modest effort to provide more schools. Their principal gesture was the establishment of a number of schools modeled on those in India. Just before 1951, Nepal had 310 primary and middle schools, 11 high schools and two colleges (the Sanskrit College founded in 1948 and the Tri-Chandra College).

In 1950, King Tribhuvan was able to gain control of the government with the help of India, and removed the Ranas from power. Nepal was then opened to the outside world.

Although King Tribhuvan had declared at the time of the formation of the new government that a parliamentary democratic system under a constitutional monarchy would be established, the creation of such a system was delayed for 8 years by the turmoil which followed the overthrow of the Ranas, until finally elections were held in 1959. However, in 1960 King Mahendra, who became king after his father's death in 1955, abolished the short-lived parliamentary regime and took personal control of the government.

With the overthrow of the Ranas, educational facilities expanded. Today Nepal has in operation 5000 primary schools with about 12,000 teachers and an estimated enrollment of 350,000 pupils which is about 25 per cent of the potential enrollment. There are 57,000 students in grades 6–10 enrolled in 645 secondary schools. However, educational standards are poor. It is reported that at least one-third of the primary school teachers are completely untrained—many are barely literate. Approximately 45 per cent of the pupils entering grade one do not enroll in grade two, and not more than 25 per cent of a first grade class can be expected to complete grade five, the terminal grade of the primary school. About fifty per cent of the students who enter high school drop out, and less than 50 per cent of those who take the final school leaving certificate examination (the SLC examination) are successful. Emphasis throughout primary and secondary school is on memory and rote learning and the situation is not different in the colleges and in the university.

There are thirty colleges affiliated with Tribhuvan University, the national university. Fourteen of the colleges are located in Kathmandu valley with the largest and oldest college being Tri-Chandra College, with a student population of about 1850 and a staff of 90.

Tribhuvan University, located in Kathmandu, was founded in 1959 and has the dual task of administering the undergraduate college examinations and the teachings of graduate courses in history, political science, economics, commerce, culture, Sanskrit, Nepali, Hindi, English, geography, physics, botany, zoology, and mathematics. There are 423 students and 67 members of the teaching staff.

Approximately half the teachers are Indians in Nepal with the Colombo plan or with the Indian Aid Mission. At present, conditions at the University are poor with classes held in old inadequate government rest houses. There are no departmental offices, no quiet areas for working, and no academic community or spirit as such among the faculty. Lectures in many cases are read from textbooks unavailable to the students, and homework or additional reading for the students is usually not assigned, or if assigned, usually not done by the students. With the exception of a few departments, nothing is done by the faculty members in the way of research or in improving or updating course material. Unfortunately, the presence of Western or modern Indian professors does little to change the system because of local politics.

An undergraduate student cannot major in mathematics in the colleges. Instead, he takes first the Intermediate Science degree (I.Sc.), then the B.Sc. degree, each degree requiring two years of study in mathematics, physics, and chemistry. It is also possible to take mathematics as part of the arts program, but this is not common.

For the I.Sc. degree which is offered at five colleges throughout Nepal, the course in mathematics includes algebra, plane geometry, solid geometry, coordinate geometry, trigonometry, differential and integral calculus, statics and dynamics. The level of knowledge reached by the students is about equal to that reached by students in a good high school in the United States. It is interesting that the mathematics courses are given concurrently without too much effort put into building on previous knowledge. At the end of two years, the student takes the university I.Sc. exam which is an external examination set by a committee of University and College professors from India and Nepal on the basis of the published syllabi. In this exam approximately 65 per cent of the students fail. There is no appeal once the results are published, and a student cannot examine his graded paper; it is destroyed soon after the test results are published. He can, however, for a fee, request immediately after the test scores are published a regrading of his paper, but only in rare instances have published results been changed upon regrading.

After the I.Sc. degree, the student who does not go abroad for his B.Sc. degree or for other studies, goes to Tri-Chandra College, which is the only college in Nepal which grants the B.Sc. degree. The program in mathematics for the bachelor's degree is a continuation of the I.Sc. program mentioned earlier. Here the level reached by the best student is equivalent to that of a second year college student in science in the United States. At the end of the two years of study, the student again takes a set of external university examinations. In these B.Sc. examinations, the number of students passing is greater than that in the I.Sc. examination for almost 50 per cent pass.

In preparing for the examinations at the end of each two year period, a student often will not study a given subject in order to concentrate on what he considers an easier subject, for example, dynamics is considered difficult as compared to statics and hydrostatics. As a consequence, at the end of the bachelor's

studies many students find it difficult to solve ordinary differential equations even of the first order, have no familiarity with Fourier Series, and do not understand partial differentiation, to name only a few topics. Emphasis in the B.Sc. course as well as in the I.Sc. course is on memorization of details just before examination time in the hope of being able to answer enough questions on the examination for a passing grade. There is much effort on the part of students and college teachers who tutor students for additional income to guess the questions which will appear on the examinations, and "guess" examination papers are found in the bookshops before examination time.

If the examinations are too difficult or if the students feel—rightly or wrongly—that the syllabus was not followed, demonstrations or strikes take place during examination time.

During trouble at the examination centers in 1966, the following comment appeared in one of the local papers:

"An inquiry should be conducted to probe the causes which led to the suspension of the Tribhuvan University examinations at two examination centers. It should be the duty of the University authorities to keep the students satisfied with their behavior. The administrative and other affairs of the University should be so planned as not to give any cause to students to feel agitated."

This comment shows, I think, the attitude of the public and students toward the examinations. Of course, there is much basis for criticism of the examination system, but it is surprising how the students are able to dictate conditions to University officials under the threat of a student strike.

After obtaining a B.Sc. degree from Tri-Chandra College, a student can major in mathematics at Tribhuvan University for two years for the M.Sc. degree. In the first year, a student takes three required courses: (i) algebra-determinants, matrices, theory of equations, vector analysis and inequalities; (ii) analysis, real variables; and (iii) infinite series, analytical geometry of three dimensions and differential equations. In addition, he must take one optional course from the listing of courses found in the Appendix. At the end of this first year, the student takes a set of four external examinations. He must pass all four examinations before starting the second year course of study. Again in the second year, there are three required courses plus one optional course. The required courses are (i) statics and dynamics; (ii) spherical harmonics and complex variables; and (iii) partial differential equations, analytical geometry and differential geometry.

Again, the student takes four examinations. If he passes these examinations, he is then awarded the M.Sc. degree. It is necessary to go abroad for any advanced study, as the Masters Degree is the highest offered by the University. At present (1966) no Nepalese holds a Ph.D. degree in mathematics.

The mathematics faculty at the University consists of three full-time members, two of whom are Indian Colombo Plan Professors, and three part-time members who also teach at Tri-Chandra College.

At present there are three students in mathematics, one in the first year who

is considered "not serious" and two in the second year. Approximately twenty students have received an M.Sc. degree in mathematics since 1959, and of these, two work in Government ministries, while the rest teach in different colleges. Mathematics is not a popular field of study because there are few jobs available to those with a degree in mathematics. One can always teach in the colleges outside of Kathmandu valley, but this is not attractive. The future of mathematics in Nepal is uncertain as almost all the students wish to go into sciences. In fact, I have been told by students that the mathematics professors encourage students to study science rather than mathematics. But the future of students in science, i.e., physics, chemistry, zoology, botany, is even more uncertain because there are few small industries and no research facilities in the country.

Appendix—Mathematics Optional Courses

(a) Spherical Trigonometry and Astronomy
(b) Statistics I*
(c) Quantum Mechanics*
(d) Hydro Mechanics*
(e) Theory of Elasticity*
(f) Theory of Numbers
(g) Projective Geometry
(h) Theory of Relativity
(i) Statistics II
(j) Functions of Complex Variable
(k) Differential Geometry
(l) Functions of a Real Variable
(m) Modern Algebra
(n) Advanced Statics and Dynamics
(o) Measure and Integration

Those marked with asterisks have been given once.

A NEW DOCTORAL PROGRAM IN MATHEMATICS EDUCATION RESEARCH

J. M. SCANDURA, University of Pennsylvania

The recent revolution in mathematics education has raised many fundamental questions and given rebirth to others. What are the objectives of mathematics education—and, how can they be used as a basis for curriculum development? What is really learned when mathematics is discovered? What does the master teacher do which makes him a master teacher—can others be taught to do these things? How does one measure mathematical knowledge and ability? To what extent can mathematical creativity be taught? These are just some of the questions about which we have only partial answers and about which more complete answers must be attained if mathematical education is to reach its potential. Unfortunately, with the immediate and pressing needs for more and better instructional materials, in-service teacher training, and the like, few con-

temporary mathematics educators have had the time to acquire the specialized training needed to conduct definitive research on such questions. They generally have too much to do already.

In recognition of the need for more research specialists in mathematics education and with support from the U. S. Office of Education, the Graduate School of Education, University of Pennsylvania has instituted a new doctoral program in mathematics education research leading to the Ed.D. and Ph.D. degrees.

This program has been especially designed for recent graduates with distinguished undergraduate records in mathematics or mathematics education. Advanced students with a master's degree in mathematics, mathematics education, statistics, or any area of behavioral science research with a strong undergraduate preparation in mathematics may be admitted into the program with advanced standing. The program is primarily intended to prepare students for positions of leadership in mathematics education research in universities, research laboratories and organizations, and federal, state, and local research agencies.

This program is interdisciplinary in nature and involves study in four core areas: *mathematics*, *recent mathematical curricula* (including elementary, secondary, and college levels), *psychology* and *educational psychology*, and *research methodology* (including measurement, statistics, experimental design, computer programming, operations research, etc.). In addition to minimal requirements in these areas, each student is expected to specialize in one or more of the core areas. Trainees will also be encouraged to elect appropriate courses in *logic*, *operations research*, *statistics*, *psycho-linguistics*, and the sciences. Independent study and research is encouraged and extensive opportunities are provided for participation in research seminars and a variety of research activities in mathematics education.

Programs may be tailored to the needs and objectives of individual students but most students will select one of two general options. The first option (Mathematics Emphasis) is weighted heavily towards mathematics whereas the second, an option which might appropriately be called Psycho-Mathematics, or the Psychology of Mathematics Learning, requires more intensive study in psychology and educational psychology along with supporting work in such areas as logic, operations research, statistics, and linguistics. The minimal mathematics requirement in the second option (Psycho-Mathematics) is the equivalent of a (steeply graded) University of Pennsylvania undergraduate major and in the first (Mathematics Emphasis) is the equivalent of a Pennsylvania master's degree. Participation in advanced seminars in mathematics education and independent study devoted to research in mathematics education is required of all candidates. For this purpose, four new courses have been instituted, the last three being devoted exclusively to research: Research in Mathematics Education, Seminar on Innovation in Mathematics Curriculum and Instruction, Research Seminar on the Psychology of Mathematics Learning.

Stipends, for qualified candidates, vary from tuition scholarships to approxi-

mately $4,000 per year plus full tuition for those with three dependents. In addition to fellowships, for full-time study, a number of research assistantships and summer research assistantships are available for $\frac{3}{4}$ time students.

Qualified college seniors and recent graduates, with an undergraduate major or master's degree in mathematics or mathematics education, are especially urged to apply. Those interested in the Ph.D. program should apply for admission to the Graduate School of Arts and Sciences; Ed.D. applicants should apply to the Graduate School of Education.

Further information on the program may be obtained by consulting the University of Pennsylvania Graduate Studies Bulletin and Undergraduate Catalogue for course descriptions and by writing Dr. Joseph M. Scandura, Associate Professor of Mathematics Education, Graduate School of Education, University of Pennsylvania, Philadelphia, Pennsylvania 19104.

THE ROLE OF AXIOMATICS AND PROBLEM SOLVING IN MATHEMATICS

E. G. BEGLE, Stanford University

For the International Congress of Mathematicians, scheduled for the summer of 1966 in Moscow, U.S.S.R., the International Commission on Mathematical Instruction chose three topics as being of particular interest at the time. These three topics were:

A. University programs in mathematics for physicists;
B. The use of the axiomatic method in the teaching of mathematics in the secondary school;
C. The role of problems in the development of mathematical activity in students.

The national commission of each of the countries adhering to the International Commission on Mathematical Instruction was asked to report on the state of affairs in its country with respect to each of these three topics. When this charge was discussed by the United States Commission on Mathematical Instruction, it was agreed that the first topic had already been thoroughly studied by the Panel on Physical Sciences and Engineering of the Committee on the Undergraduate Program in Mathematics. On the other hand, it was agreed that there is a wide diversity of opinion in this country with respect to the other two topics, in particular that concerning the axiomatic method.

The United States Commission felt that any report to the International Commission should reflect this wide range of opinions and that an effective way of doing this would be to ask individual mathematicians and mathematics teachers, representing various points of view, to prepare statements of their own opinions on these matters.

The United States Commission felt that the set of these statements could not only form the report to the International Commission but also, if made widely available in the United States, encourage discussion of these important topics and, hopefully, reduce misunderstandings in the mathematical community.

E 1953. *Proposed by D. J. Newman, Yeshiva University*

What is the maximum possible number of real solutions for the system $y=e^x$, $P(x, y)=0$, if $P(x, y)$ is required to be a polynomial of degree n?

E 1954. *Proposed by D. J. Newman, Yeshiva University*

Prove that there is no position in which an $n\times n$ square can cover more than $(n+1)^2$ integral lattice points.

SOLUTIONS OF ELEMENTARY PROBLEMS

Cutting Up a Chain

E 1798 [1965, 665]. *Proposed by Pete Said, Fresno State College, California*

A chain has n links and each link weighs one unit. p cuts are to be made in the chain in such a manner that the resulting subchains, together with the p cut links and a balance scale, can be used to weigh every multiple of the unit weight from 1 to n. Find p in terms of n.

I. *Solution by C. B. A. Peck, State College, Pa.* Assume the chain is open (not endless) and allow any number of links to be placed in either pan of the scale. With p cut links one can weigh from 1 to p. Add a chain of k links and one can weigh from $k-p$ to $k+p$. If $p+1\geqq k-p$, there is no gap. If we let $k=2p+1$, we can weigh from 1 to $3p+1$. Proceeding by induction, if we can weigh from 1 to $3^{k+1}p+(3^{k+1}-1)/2$ by p cut links and chains with $2p+1$, $3(2p+1)$, $\cdots$, $3^k(2p+1)$ links, then we can weigh from 1 to $3^{k+1}p+(3^{k+1}-1)/2+3^{k+1}(2p+1)$ $=3^{k+2}p+(3^{k+2}-1)/2$ by adding a chain with $3^{k+1}(2p+1)$ links, providing the number of chains (the exponent of the 3's) does not exceed $p+1$. Then p cut links are necessary and (if distributed as described) sufficient for a chain of n links to furnish the desired weights if

$$3^p p + (3^p + 1)/2 < n \leqq 3^{p+1}p + (3^{p+1} - 1)/2.$$

Thus p is any integer k ($\leqq n$) such that $3^{k+1}\geqq(2n+1)/(2k+1)$. For the smallest such p there is no explicit formula.

II. *Solution by D. C. B. Marsh, Colorado School of Mines.* If the links must be placed in one scale pan, this is essentially problem E 636 [1945, 276]. If, however, links may be placed in either pan of a two-pan balance, then, by analogous reasoning, p is determined by

$$3^p(p - \tfrac{1}{2}) - \tfrac{1}{2} < n \leqq 3^{p+1}(p + \tfrac{1}{2}) - \tfrac{1}{2}.$$

Also solved by W. Bluger, R. B. Eggleton (Australia), Michael Goldberg, R. F. Jackson, Walter Penney, Robin Sibson (England), and D. L. Silverman.

A New Line Associated with a Given Triangle

E 1799 [1965, 665]. *Proposed by Joseph Langr, Prague, Czechoslovakia*

On the sides BC, CA, AB of the triangle $ABC \equiv T$ are chosen points A_1, A_2; B_1, B_2; C_1, C_2 in such a way that $AC_1 = AB_2 = BC$, $BA_1 = BC_2 = CA$, $CB_1 = CA_2 = AB$. (1) Show that the orthocenters H_1, H_2, H_3, H of the triangles AB_2C_1, BC_2A_1, CA_2B_1 and T lie on the Euler line of the triangle formed by the lines B_2C_1, C_2A_1, A_2B_1. (This Euler line is parallel to the line joining the incenter and circumcenter of T.) (2) Show also that $HH_1 : HH_2 : HH_3 = \cos A : \cos B : \cos C$.

Solution by J. M. Quonian, Saint-Etienne, France. Denote the circumcenter and the incenter of triangle T by O and I. Employing a conjugate coordinate system having I as origin and the inradius r of T as unity, we may let

$$(a, 1/a), \qquad (b, 1/b), \qquad (c, 1/c)$$

denote the coordinates of the points A'', B'', C'' of contact of the incircle of T with the sides BC, CA, AB. For later convenience, set

$$s = a + b + c, \qquad t = bc + ca + ab, \qquad p = abc.$$

The coordinates of A are $x_A = 2bc/(b+c)$, $y_A = 2/(b+c)$, with similar expressions for the coordinates of B and C. The coordinates of B_2 are

$$x_{B_2} = 2bc/(b + c) - 2ab(b - c)/(c + a)(a + b),$$
$$y_{B_2} = 2/(b + c) + 2a(b - c)/b(c + a)(a + b),$$

and those of C_1 are

$$x_{C_1} = 2bc/(b + c) + 2ca(b - c)/(c + a)(a + b),$$
$$y_{C_1} = 2/(b + c) - 2a(b - c)/c(c + a)(a + b).$$

The coordinates of C_2 and A_1, and of A_2 and B_1, are given by similar expressions. Denoting by $A'B'C'$ the triangle with sides along the lines B_2C_1, C_2A_1, A_2B_1, the coordinates of vertex A' are

$$x_{A'} = 2bc/(b + c) - 2a(a^2 - bc)/(c + a)(a + b),$$
$$y_{A'} = 2/(b + c) + 2(a^2 - bc)/a(c + a)(a + b).$$

There are similar expressions for the coordinates of B' and C'. The circumcenter O' of triangle $A'B'C'$ has coordinates

$$x_{O'} = 2(t^2 + ps)/(ts - p), \qquad y_{O'} = 2(s^2 + t)/(ts - p),$$

and one sees that

$$\overrightarrow{IO'} = \overrightarrow{IA} + \overrightarrow{IB} + \overrightarrow{IC}.$$

The differences $x_{O'} - x_{A'}$ and $y_{O'} - y_{A'}$ are equal to $2a$ and $2/a$ respectively, so that *the circumradius of triangle $A'B'C'$ is twice the inradius of triangle T.*

The coordinates of the orthocenter H' of triangle $A'B'C'$ are

$$x_{H'} = 2(t^2 + ps)/(ts - p) - 2s = x_{O'} - 2x_{H''},$$
$$y_{H'} = 2(s^2 + t)/(ts - p) - 2t/p = y_{O'} - 2y_{H''},$$

where H'' is the orthocenter of triangle $A''B''C''$. The coordinates of the orthocenter H of triangle T are

$$x_H = 2(t^2 - ps)/(ts - p), \qquad y_H = 2(s^2 - t)/(ts - p),$$

and those of the orthocenter H_1 of triangle AB_2C_1 are

$$x_{H_1} = 2bc/(b + c) - 2a(b^2 + c^2)/(c + a)(a + b),$$
$$y_{H_1} = 2/(b + c) - 2a(b^2 + c^2)/bc(c + a)(a + b).$$

Similar expressions give the coordinates of the orthocenter H_2 of triangle BC_2A_1 and the orthocenter H_3 of triangle CA_2B_1. The coordinates of the circumcenter O of triangle T are

$$x_O = 2ps/(ts - p), \qquad y_O = 2t/(ps - t).$$

The equation of the line H_1H_2 is

$$psy - tx + 2(t^3 - ps^3)/(ts - p) = 0,$$

which is parallel to the line OI and has the points O', H_3, H, H' on it.

Finally, we have

$$\begin{aligned}(HH_1)^2 &= (x_H - x_{H_1})(y_H - y_{H_1}) \\ &= [2a(b^2 + c^2)s/(ts - p)][2(b^2 + c^2)t/bc(ts - p)] \\ &= [(b^2 + c^2)^2/b^2c^2][4pts/(ts - p)^2],\end{aligned}$$

whence

$$HH_1 = [-(b^2 + c^2)/2bc][4\sqrt{pts}/(p - ts)].$$

Since $-(b^2+c^2)/2bc = \cos A$, we have

$$HH_1/\cos A = 4\sqrt{pts}/(p - ts) = 4r(IH'')/[r^2 - (IH'')^2].$$

A Construction Related to a Given Circle

E 1800 [1965, 666]. *Proposed by Joseph Langr, Prague, Czechoslovakia*

Given a circle (O), a point C on it, and two points A, B not on the circle. Find a point S on circle (O) such that SC bisects the angle ASB.

I. *Solution by Joseph Basile, Brussels, Belgium.* Let SA, SB cut circle (O) in X and Y. Then X and Y are symmetric in the diameter d of (O) through C. Choose on (O) any three pairs of points X_i, Y_i $(i=1, 2, 3)$ such that each pair

is symmetric in d. Let AX_i and BY_i cut (O) in X_i' and Y_i'. Then X_i' and Y_i' form two homographic ranges on (O) whose double points (constructed by the classical method) are the possible positions for S.

II. *Solution by R. H. F. Denniston, University of Leicester, England.* Find inverses, with respect to C as center, of (O), A, B; these will be a straight line o' and points A' and B'. Bisect $A'B'$ at M and draw the internal and external bisectors of angle $A'CB'$. Parallel to these bisectors, draw MP and MQ through M to meet o' in P and Q. Through C draw a line parallel to o' to meet MP and MQ in D and E. Find a point S' on o' such that $(S'P)(S'Q)=(CD)(CE)$. Then S, the inverse of S', is the required point.

Proof. Take MP and MQ as x and y coordinate axes; then the product xy has the same value at S' and at C. Now consider the locus of a point whose joins to A' and B' are equally inclined to the axes; the equation of this locus is easily seen to be of the form $xy=$constant. But C is on the locus; so S' is on the locus too, and the angles $CA'S'$, $S'B'C$ are equal. Now angle $CA'S'$ is equal to angle ASC, by similar triangles; similarly, angles $S'B'C$, CSB are equal. Thus SC bisects angle ASB.

Also solved in a manner similar to solution I by R. H. F. Denniston, and analytically by P. A. Scheinok.

A Zeta-function Summation

E 1801 [1965, 666]. *Proposed by Ralph Greenberg, University of Pennsylvania*
Prove that

$$\sum_{k=1}^{\infty} \zeta(2k)/2^{2k}(2k^2+k) = \log(\pi/e),$$

where $\zeta(n)=\sum_{j=1}^{\infty} j^{-n}$, the Riemann zeta function.

I. *Solution by D. C. B. Marsh, Colorado School of Mines.* We have

$$\sum_{k=1}^{\infty} \zeta(2k)/2^{2k}(2k^2+k) = \sum_{k=1}^{\infty}\sum_{j=1}^{\infty} (2j)^{-2k}/(2k^2+k),$$

replacing the ζ-function by its definition. We reverse the order of summation, decompose the denominator into partial fractions and sum, obtaining

$$\sum_{j=1}^{\infty} \{2\log(2j) - (2j+1)\log(2j+1) + (2j-1)\log(2j-1) + 2\}.$$

We consider the corresponding finite sum and use Stirling's formula, to get

$$\begin{aligned}\sum_{j=1}^{n} \{2\log(2j) - (2j+1)\log(2j+1) + (2j-1)\log(2j-1) + 2\} &= 2n\log(2e) + 2\log(n!) - (2n+1)\log(2n+1)\\ &\approx (2n+1)\log\frac{2n}{2n+1} + \log\pi.\end{aligned}$$

As $n\to\infty$, this last quantity approaches $-1+\log\pi=\log(\pi/e)$.

II. *Solution by A. E. Danese, State University of New York at Buffalo.* The result is immediate if we let $z=1$ in

$$\sum_{k=1}^{\infty}\zeta(2k, z)/2^{2k}(2k^2+k) = (2z-1)\log(z-\tfrac{1}{2}) - 2z + 1 + \log 2\pi - 2\log\Gamma(z),$$

where $\zeta(s, z)=\sum_{n=0}^{\infty}(z+n)^{-s}$, $z\neq 0, -1, -2, \cdots$. (Burnside's formula, *Higher Transcendental Functions*, vol. I, Erdelyi, et al., p. 48, (11).)

Also solved by L. F. Epstein, Edward Garelis, S. H. Greene, Sidney Heller, Stephen Hoffman, R. S. Jackson, M. S. Klamkin, David Klarner & Martin Muldoon, E. S. Langford, F. C. Smith, David Zeitlin and the proposer.

A Consequence of the Mean Value Theorem

E 1802 [1965, 666]. *Proposed by Dov Avishalom, Tel-Aviv, Israel*

For functions of class C_n prove that

$$f^{(n)}(a) = \lim_{h\to 0}\left\{\frac{1}{h^n}\sum_{k=0}^{n}\left[(-1)^{n-k}\binom{n}{k}f(a+kh)\right]\right\}.$$

I. *Solution by M. S. Klamkin, Ford Scientific Laboratory.* First, it is well known that

$$\sum_{k=0}^{n}(-1)^k k^r\binom{n}{k} = \begin{cases}0 & (r=0, 1, \cdots, n-1)\\ n! & (r=n)\end{cases}$$

(Easily proved by differentiating $(1-x)^n=\sum_{k=0}^{n}(-1)^k\binom{n}{k}x^k$ r times ($r\leqq n$) and evaluating at $x=1$.) Consequently, it follows from L'Hospital's rule that the desired limit equals

$$\frac{1}{n!}\left\{D^n\sum_{k=0}^{n}(-1)^{n-k}\binom{n}{k}F(a+kh)\right\}_{h=0} = F^n(a).$$

II. *Solution by D. C. B. Marsh, Colorado School of Mines.* A proof is given in Wilhelm Maak, *An Introduction to Modern Calculus*, pp. 85–86, as an immediate consequence of the Mean Value Theorem for higher differential quotients for functions of class C_n.

Also solved by J. M. Ash, R. J. Cormier, S. H. Greene, D. M. Hancasky, Stephen Hoffman, J. E. Humes, Jr., E. S. Langford, Norman Miller, M. J. Pascual, B. E. Rhoades, P. A. Scheinok, Al Somayajulu, Sidney Spital, Julius Vogel, Benjamin Volk, P. H. Young, David Zeitlin, and the proposer.

Ash notes the generalization: Let $a_0, a_1, \cdots, a_n$ be any $n+1$ distinct real numbers, and let f be any function such that $f^{(n)}(a)$ exists, then there is a unique set of numbers $b_0, \cdots, b_n$ such that

$$\lim_{h\to 0}\left\{\frac{1}{h^n}\sum_{k=0}^{n}b_k f(a+a_k h)\right\} = f^{(n)}(a).$$

A Mean Value Property

E 1803 [1965, 666]. *Proposed by F. P. Callahan, Blue Bell, Pa.*

Find the most general form of $f(x)$, defined for all real x, such that

$$\frac{f(v)-f(u)}{v-u}=f'(pu+qv) \tag{1}$$

holds for all u, v; where p, q are positive with $p+q=1$.

Solution by Robert Coen, Brooklyn, N. Y. First we note the symmetry of (1) in u, v so that

$$f'(pv+qu)=f'(pu+qv), \tag{2}$$

whence, if $p\neq q$, f' is constant and f is linear.

On the other hand, if $p=q=\frac{1}{2}$, we may differentiate (1) with respect to u and to v and add the results, obtaining

$$\frac{f'(v)+f'(u)}{v-u}-2\frac{f(v)-f(u)}{(v-u)^2}=0$$

which, because of (1), gives

$$\frac{f'(v)+f'(u)}{2}=f'\left(\frac{u+v}{2}\right),$$

and this implies that f' is linear, so that f is quadratic. Finally, $f(x)=a+bx$, and $f(x)=a+bx+cx^2$ with $p=q=\frac{1}{2}$ do satisfy (1).

Also solved by R. A. Avelsgaard, S. H. Greene, D. M. Hancasky, R. F. Jackson, M. S. Klamkin, B. G. Klein, D. C. B. Marsh, R. F. Rossa & R. J. Gazik, and Richard Sinkhorn.

Virtually the same problem is in Pi Mu Epsilon Journal, vol. 3, No. 1, 1959, p. 18, prob. 103.

The Taylor Operator

E 1804 [1965, 666]. *Proposed by Carmen Artino, John Carroll University*

Let $\mathfrak{V}$ be the vector space (over the real field) of all polynomials of degree less than n. Let $\mathbf{D}$ denote the differentiation operator on $\mathfrak{V}$ and $\mathbf{I}$ the identity transform on $\mathfrak{V}$; i.e., $f(x)\in\mathfrak{V}$, $f(x)\mathbf{D}=f'(x)$ and $f(x)\mathbf{I}=f(x)$. Let $\mathbf{T}$ be a linear transformation on $\mathfrak{V}$ given by $f(x)\mathbf{T}=f(x+1)$. Show that

$$\mathbf{T}=\mathbf{I}+\frac{\mathbf{D}}{1!}+\frac{\mathbf{D}^2}{2!}+\cdots+\frac{\mathbf{D}^{n-1}}{(n-1)!}.$$

Solution by Simon Vatriquant, Brussels, Belgium. Since $f(x)$ is a polynomial, the Taylor expansion exists and terminates. The degree of the polynomial being

less than n, we have $f(x)\mathbf{D}^{n+k} \equiv 0$ for $k \geqq 0$. Consequently

$$f(x+1) = f(x) + \frac{1}{1!}f'(x) + \frac{1^2}{2!}f''(x) + \cdots + \frac{1^{n-1}}{(n-1)!}f^{(n-1)}(x)$$

or

$$f(x)\mathbf{T} = f(x)\mathbf{I} + f(x)\mathbf{D}/1! + f(x)\mathbf{D}^2/2! + \cdots + f(x)\mathbf{D}^{n-1}/(n-1)!.$$

According to the distributivity property of the operators we have

$$f(x)\mathbf{T} = f(x)[\mathbf{I} + \mathbf{D}/1! + \mathbf{D}^2/2! + \cdots + \mathbf{D}^{n-1}/(n-1)!],$$

as desired.

Also solved by S. S. Bartnikowski, D. R. Beuerman, Béla Bollobás (Hungary), W. G. Dotson, Jr., J. L. Ercolano, E. W. Ewing, G. G. Ford, E. A. Franz, R. B. Grayless, S. H. Greene, D. M. Hancasky, Stephen Hoffman, Edward Hook, J. F. Horrell, M. S. Klamkin, B. G. Klein, E. S. Langford, R. E. Maas, D. C. B. Marsh, A. P. Mella, J. W. Mentele, C. J. Parry & D. H. Faust, M. J. Pascual, B. E. Rhoades, Henry Ricardo, R. F. Rossa & R. J. Gazil, P. A. Scheinok, G. F. Schumm, N. T. Sheth, Robin Sibson (England), Sidney Spital, Julius Vogel, Benjamin Volk, David Vosholz, Nolan Wallach, Max Weinryb, D. R. Wilder, O. H. Young, D. S. Zave, David Zeitlin, and the proposer.

Ercolano remarks that this is a special case of a well-known result valid in the space of all analytic functions, viz.,

$$\mathbf{T}_h = \exp[h\mathbf{D}] = \mathbf{I} + h\mathbf{D} + h^2\mathbf{D}^2/2! + \cdots + h^n\mathbf{D}^n/n! + \cdots,$$

where $T_h f(x) = f(x+h)$.

The problem is found in many texts. See Birkhoff and MacLane *Survey of Modern Algebra*, p. 214, prob. 17(b); Halmos, *Finite Dimensional Vector Spaces*, p. 41, ex. 3; Jacobson, *Lectures on Abstract Algebra*, vol. II, p. 38, prob. 2.

Inscribed Triangle in a Minkowski Plane

E 1805 [1965, 780]. *Proposed by I. J. Schoenberg, U. S. Army Research Center, University of Wisconsin*

We wish to inscribe a triangle ABC, having given sides a, b, c, in the circle $\|x\| = r$ of the Minkowski (Banach) plane M_2 of points $x = (x_1, x_2)$ with the norm $\|x\| = \max(|x_1|, |x_2|)$. Since M_2 is a metric space, it is necessary for the possibility of this construction that (i) a, b, c satisfy the triangle inequality, and (ii) a, b, and c do not exceed the diameter $2r$. Show that these conditions are also sufficient.

Solution by A. B. Carter, Cornell College, Mt. Vernon, Iowa. We may take $0 < a \leqq b \leqq c \leqq 2r$ and $c \leqq a+b$. For P, Q in M_2 denote the normed distance between P and Q by $|PQ|$. Let $A = (c-r, r)$, $B = (-r, r-a)$, and $C = (c-b-r, r)$. Clearly, triangle ABC is inscribed in the "circle" $\|x\| = r$ and $|AB| = \max(|-r-c+r|, |r-a-r|) = \max(c, a) = c$, $|AC| = \max(|c-b-r-c+r|, 0)$

$=\max(b, 0)=b$, and $|BC|=\max(|c-b-r+r|, |r-r+a|)=\max(c-b, a)$. Since $c\leqq a+b$, $c-b\leqq a$ and $|BC|=a$. This proves sufficiency.

Also solved by R. G. Albert, Béla Bollobás (Hungary), E. O. Buchman, D. I. A. Cohen, D. C. B. Marsh, Wayne Roberts, and the proposer.

Related Inequalities in a Triangle

E 1806 [1965, 781]. *Proposed by Kaidy Tan, Fukien Normal College, China*

On two sides AB, AC of triangle ABC describe equilateral triangles ABD, ACE outside the given triangle. Let G, H be the centroids of these two triangles respectively, and let M be the midpoint of BC. Prove that $AC\geqq AB$ if and only if $MG\geqq MH$.

Solution by C. S. Venkataraman, Trichur, India. Let $AB=c$, $AC=b$, and let L, N be their respective midpoints. Since triangle ABD is equilateral, DG passes through N and is perpendicular to AB, and also $GL=c/2\sqrt{3}$. Further, LM is parallel to AC. Therefore $LM=b/2$ and $\measuredangle BLM=\measuredangle A$. Similarly $HN=b/2\sqrt{3}$, $NM=c/2$ and $\measuredangle CNM=\measuredangle A$. Note that $\measuredangle GLM=\pi/2+\measuredangle A$. The cosine formula now gives us

$$MG^2 = c^2/12 + b^2/4 + bc\sin A/2\sqrt{3},$$
$$MH^2 = b^2/12 + c^2/4 + bc\sin A/2\sqrt{3}.$$

Then $MG^2-MH^2=(b^2-c^2)/6$. Therefore $AC^2\gtreqless AB^2$ according as $MG^2\gtreqless MH^2$ and conversely. Hence $AC\gtreqless AB$ if and only if $MG\gtreqless MH$.

Also solved by K. V. Achuthan & R. Sivaramakrishnan (India), R. G. Albert, P. N. Bajaj, V. K. Batra (India), A. N. Behr, Béla Bollobás (Hungary), D. I. A. Cohen, R. H. Denniston (England), Ragnar Dybvik (Norway), R. B. Eggleton (Australia), Hyman Gabai & Steven Szabo, Michael Goldberg, D. M. Hancasky, Ned Harrell, W. E. Hoff, Stephen Hoffman, John Isbell, Mrs. M. R. Iyer (India), M. S. Klamkin, J. D. E. Konhauser, F. Lauenberger (Switzerland), D. C. B. Marsh, Norman Miller, Barbara W. Nason, C. B. A. Peck, J. M. Quoniam (France), Simeon Reich (Israel), L. A. Ringenberg, P. A. Scheinok, R. R. Schryer, Robin Sibson (England), Al Somayajulu, Sidney Spital, Janet Tang, C. Van de Vyle (Belgium), Hazel S. Wilson, J. W. An Identity in Derivatives

E 1807 [1965, 781]. *Proposed by Peter Rolland, Jr., University of Illinois*

Let p be a polynomial of degree n. Prove that

$$\sum_{k=0}^{n} \frac{p^{(k)}(0)}{(k+1)!}x^{k+1} = \sum_{k=0}^{n} (-1)^k \frac{p^{(k)}(x)}{(k+1)!}x^{k+1}, \qquad p^{(0)}(x)\equiv p(x).$$

I. *Solution by C. Van de Vyle, Evergem, Belgium.* We put $M(x)$ and $N(x)$ for the left and right members, respectively, of the proposed identity. Because $M(x)$ and $N(x)$ are polynomials and $M(0)=N(0)=0$, it is sufficient to prove that $dM/dx=dN/dx$.

$$\frac{dM}{dx} = \sum_{k=0}^{n} \frac{p^{(k)}(0)}{k!} x^k = p(x), \qquad \text{(Maclaurin)}$$

$$\frac{dN}{dx} = \sum_{k=0}^{n} (-1)^k \frac{p^{(k)}(x)}{k!} x^k + \sum_{k=0}^{n} (-1)^k \frac{p^{(k+1)}(x)}{(p+1)!} x^{k+1}$$

$$= p(x) + (-1)^n \frac{p^{(n+1)}(x)}{(n+1)!} x^{n+1} = p(x),$$

from which it is evident that $M(x) \equiv N(x)$.

II. *Solution by A. W. Roberts, Macalester College.* For any t, s, the Taylor expansion gives

$$p(t) = \sum_{k=0}^{n} \frac{p^{(k)}(s)}{k!} (t-s)^k = p(s) + \sum_{k=0}^{n} \frac{p^{(k+1)}(s)}{(k+1)!} (t-s)^{k+1},$$

the second summation extended to n since $p^{(n+1)}(x) \equiv 0$. If we set $t = x$, $s = 0$,

$$p(x) - p(0) = \sum_{k=0}^{n} \frac{p^{(k+1)}(0)}{(k+1)!} x^{k+1}. \tag{1}$$

If we set $t = 0$, $s = x$,

$$p(0) - p(x) = \sum_{k=0}^{n} \frac{p^{(k+1)}(x)}{(k+1)!} (-x)^{k+1}. \tag{2}$$

Multiplication of (2) by -1 and comparison with (1) gives the desired result.

III. *Solution by N. J. Fine, Pennsylvania State University.* Let

$$P(a, t) = \sum_{k=0}^{n} \frac{p^{(k)}(a)}{(k+1)!} t^{k+1}.$$

Then

$$D_t P(a, t) = \sum_{k=0}^{n} p^{(k)}(a) t^k / k! = p(a + t).$$

Since $P(a, 0) = 0$, we have

$$P(a, t) = \int_0^t p(a + u)\,du = \int_a^{a+t} p(u)\,du.$$

In the problem, the first sum is $P(0, x) = \int_0^x p(u)\,du$, and the second is

$$-P(x, -x) = -\int_x^0 p(u)\,du = \int_0^x p(u)\,du.$$

Also solved by R. G. Albert, A. D. Anderson, Robert Baillie, R. A. Bell, Béla Bollobás (Hungary), J. L. Brown, Jr., E. O. Buchman, John Burslem, C. A. Church, Jr., D. I. A. Cohen, R. C. Cormier, G. C. Dodds, Ragnar Dybvik (Norway), R. B. Eggleton (Australia), Phillip Fung, P. K. Garlick, Frederick Gray & R. I. Price, Richard Guilfoyle, D. M. Hancasky, Bill Helliwell, Stephen Hoffman, David Huestis, Mrs. M. R. Iyer (India), R. F. Jackson, G. G. Killough, P. G. Kirmser, M. S. Klamkin, Kenneth Kramer, E. S. Langford, R. E. Maas, J. E. MacDonald, Jr., B. D. McLemore, Beatrice Margolis, C. F. Marion, D. C. B. Marsh, Norman Miller, Q. G. Mohammed (India), Alexander Morgan, R. E. Moyer, P. V. O'Neil, C. B. A. Peck, Harsh Pittie, J. M. Quoniam (France), Simeon Reich (Israel), Henry Ricardo, P. A. Scheinok, P. S. Schnare, Robin Sibson (England), Richard Sinkhorn, David A. Smith, Franklin C. Smith, Al Somayajulu, G. P. Speck, M. R. Spiegel, Sidney Spital, Preston Stein, Julius Vogel, Benjamin Volk, A. W. Warrick, Gerald Werner, B. D. Wick, H. H. Wong, K. L. Yocom, P. H. Young, David Zeitlin, and the proposer.

Bell notes the following more general result: For any positive integer r and polynomial p of degree n, we have

$$\sum_{k=0}^{n} p^{(k)}(0)x^{k+r}/(k+r)! = \sum_{k=0}^{n} (-1)^k x^{k+r} p^{(k)}(x)\binom{k+r-1}{r-1} \Big/ (k+r)!.$$

A Max-min Problem

E 1808 [1965, 781]. *Proposed by H. T. Croft, Cambridge University, England*

C is a configuration of 5 points P_i $(i=1, \cdots, 5)$ in a closed domain D. Find $M=\max_C \min_{i\neq j} P_iP_j$ in the following cases:

(i) D is the unit square;

(ii) D is the unit equilateral triangle;

(iii) D is the unit circle;

(iv) D is the surface of the unit sphere.

In (iv) P_iP_j may be interpreted either as Euclidean or great-circle distances; essentially the same problem results.

Solution by D. C. B. Marsh, Colorado School of Mines. (i) $M=2^{-1/2}$. Consider four closed $\frac{1}{2}$-unit squares whose union is the given unit square. At least one of these must contain at least two of the five points. The maximum spacing of two such points is $2^{-1/2}$, occurring when the points are diagonally opposite. This value is also attainable for the unit square when the five points are placed at the vertices and center of the square.

(ii) $M=\frac{1}{2}$. As in (i), partition the triangle into four $\frac{1}{2}$-unit equilateral triangles and locate the points at any five of the six vertices of the $\frac{1}{2}$-unit triangles.

(iii) $M=2 \sin (\pi/5)$. Partition the circle into five congruent sectors and space the points equidistant about the circumference. Were two points to lie within a circular sector of arc $\phi(\phi \leqq 2\pi/5)$ their greatest separation would be $\max(1, 2 \sin \frac{1}{2}\phi) \leqq 2 \sin (\pi/5)$.

(iv) $M=\frac{1}{2}\pi$. This is possible for one point at the north pole and the other four 90° apart along the equator. Were one point arbitrarily labelled the north pole and the other four located farther than $\pi/2$ from it, then these four would have to lie in the southern hemisphere proper. Partitioning the hemisphere into

four congruent regions, we observe that the max-min for these four points cannot exceed $\pi/2$.

This is the great-circle interpretation. When Euclidean distance is used, the same argument leads to $M=\sqrt{2}$.

Also solved by Michael Goldberg, Norman Miller, C. B. A. Peck, and the proposer.

Goldberg refers to a paper by K. Schütte and B. L. van der Waerden, *Auf welcher Kugel haben, 5, 6, 7, 8, oder 9 Punkte mit Mindesabstand Eins Platz?*, Math. Annalen, 123 (1951) 96–124.

Farmer Jones Rides Again

E 1809 [1965, 781]. *Proposed by Pete Said, Fresno State College*

A square has sides of length 2. It is to be rolled along a curve without slipping and so that the center of the square moves in the horizontal line $\{(x, y) \mid y=2^{1/2}\}$. What is the equation of the principal period of the curve?

Solution by A. P. Boblett, U. S. Naval Ordnance Laboratory, Corona, Calif. When $x=0$: $y=\sqrt{2}-1$; $y'=0$; and $y''<0$. Assume $s=-y'$, where s is the distance measured along the curve.

$$s=-y'=\int [1+(y')^2]^{1/2}dx: \qquad -y''=[1+(y')^2]^{1/2}: \qquad (y'')^2=1+(y')^2.$$

By inspection a solution is $y=A\pm\cosh(x)$, and a solution which meets the initial conditions is

$$y=\sqrt{2}-\cosh(x).$$

It is easily verified that the center of the square lies on $y=\sqrt{2}$ for $-\sinh^{-1}(1) \leqq x \leqq \sinh^{-1}(1)$.

Also solved by T. J. Bishop, D. I. A. Cohen, Richard Gisselquist, R. F. Jackson, Sidney Spital, the proposer, and the solvers of E 1668.

This is essentially a repeat of E 1668 [1965, 82], where the result agrees with the above except for a shift of the y-axis.

Sum of the Cubes of the Digits

E 1810 [1965, 781]. *Proposed by John Harvey and John E. Wetzel, University of Illinois*

For each natural number n let $C(n)$ be the sum of the cubes of the decimal digits of n. Show that for every n, iterating C eventually leads to one of the following repeating cycles: 1, 55-250-133, 136-244, 153, 160-217-352, 370, 371, 407, 919-1459.

Solution by Stephen Hoffman, Trinity College, Hartford, Conn. Let $B=\{1, 55, 133, 136, 153, 160, 217, 244, 250, 352, 370, 371, 407, 919, 1459\}$. Then it is easily shown that $C(B)=B$. If $S=\{n \mid n\in I^+$ and there exists $p\in I^+$ such that $C^p(n) \in B\}$, examination shows that all one digit positive integers are in S. If all k-

digit integers are in S and if n has $k+1$ digits, then $C(n)=q+d^3$, where $q\in S$, and d is one digit of n, so $0\leqq d\leqq 9$. If $d=0$ then $C(n)\in S$. Examination of the 126 numbers given by $1\leqq d\leqq 9$ shows that each has an iterate, under C, which is in B.

Also solved by D. C. B. Marsh, P. K. Subramanian, Robin Sibson (England), and the proposer.

C. B. A. Peck quotes Sierpinski (*Elementary Theory of Numbers*, Warszawa, 1964, p. 268) that this result was shown by Iseki, Proc. Japan. Acad., 36 (1960), pp. 578–583. See also B. M. Stewart, *Sums of functions of digits*, Can. J. Math., 12 (1960) 374–389.

A Problem of Partitions

E 1811 [1965, 781]. *Proposed by Irving Adler, North Bennington, Vermont*

If $a_1, \cdots, a_n$ are distinct positive integers, the positive integer s is said to be attainable through $\{a_1, \cdots, a_n\}$ if there exist nonnegative integers $x_1, \cdots, x_n$ such that $x_1a_1+\cdots+x_na_n=s$. The critical number for a set is the least positive integer N such that every integer $n\geqq N$ is attainable through that set.

If a and d are relatively prime, prove that the critical number for $\{a, a+d, a+2d\}$ is $(m+d-1)a-d+1$, where m is the least positive integer $\geqq\frac{1}{2}(a-1)$.

Solution by Alfred Brauer, University of North Carolina and Wake Forest College. Let $a_1, a_2, \cdots, a_k$ be relatively prime positive integers and $k>2$. We consider the Diophantine equation

$$x_1a_1 + x_2a_2 + \cdots + x_ka_k = n. \tag{1}$$

Let $f(a_1, \cdots, a_k)$ be the largest integer for which (1) has no solution in positive integers $x_1, \cdots, x_k$. Then

$$g(a_1, \cdots, a_k) = f(a_1, \cdots, a_k) - a_1 - a_2 - \cdots - a_k$$

is the largest integer not representable by (1) with nonnegative integers $x_1, \cdots, x_k$.

G. Frobenius, in his lectures, proposed the following problem: Find upper bounds for $f(a_1, \cdots, a_k)$. Such bounds were obtained by I. Schur (see [2]) and in my papers [2], [3], [4] with B. M. Seelbinder and J. E. Shockley, and by Schockley [7]. In [2] the exact bound was obtained for the case that $a_1, a_2, \cdots, a_k$ are consecutive integers. This was generalized by J. B. Roberts [6] for the case of an arithmetic progression $a, a+d, \cdots, a+(k-1)d$, with $d>1$. Simpler proofs of this generalization were given in my review [5] of [6] and by P. T. Bateman [1]. Problem E 1811 is the case $k=3$.

ADVANCED PROBLEMS

Solutions of Advanced Problems should be sent to J. Barlaz, Rutgers—The State University, New Brunswick, N. J. 08903. Solutions of Advanced Problems in this issue should be typed or written legibly on separate signed sheets and should be mailed before July 31, 1967. Contributors (in the United States) who desire acknowledgement of receipt of their solutions are asked to enclose self-addressed stamped postcards.

5450. *Proposed by H. Kestelman, University College, London, England*

A real-valued function f defined on a vector space V is called a pseudo-norm if, for all x, y in V,

$$f(x + y) \leqq f(x) + f(y) \quad \text{and} \quad f(-x) = f(x).$$

Suppose $f_1, f_2, \cdots$ are pseudo-norms in V, and E_0 is the set of those v in V with $\sum_n f_n(v) < \infty$; show that E_0 is either empty or is a group under addition.

If $\epsilon_1, \epsilon_2, \cdots$ is a sequence of elements of V and S_ϵ is the set of all v with $\sum_n f_n(v+\epsilon_n) < \infty$, show that if S_ϵ includes at least two elements then E_0 is infinite and S_ϵ is a translate of E_0. Deduce when $V = R_n$, that if E_0 has positive interior Lebesgue measure then S_ϵ is either empty or else equal to R_n.

5451. *Proposed by J. P. Williams and Thomas Crimmins, University of Michigan*

It is well known that if T is a bounded linear operator from a Hilbert space H into itself, then T maps H *onto* itself if and only if its adjoint is bounded below: $\|T^*x\| \geqq C\|x\|$, $(x \in H)$ for some positive constant C (see Dunford and Schwartz, Vol. 1, p. 488, for example).

Show that the weaker condition $\|Tx\| + \|T^*x\| \geqq C\|x\|$ $(x \in H)$ does not imply that T is one-to-one or that the range of T is dense. Does this condition imply that the range of T is closed?

5452. *Proposed by E. S. Barnes, University of Malaya, Kuala Lumpur*

Let $n = 2m+1$, $n > 3$. Show that n real numbers $x_1, x_2, \cdots, x_n$ have the property that the sum of any m of them is less than or equal to the sum of the remaining $m+1$ if and only if $\mathbf{x} = (x_1, x_2, \cdots, x_n)$ is a nonnegative linear combination of the $2n$ vectors $\mathbf{E} \pm \mathbf{e}_i$, $(i = 1, \cdots, n)$, where $\mathbf{e}_i$ are the unit vectors and $\mathbf{E} = \sum_1^n \mathbf{e}_i$.

Let S be a semigroup with three generators g_1, g_2, g_3, in which $x^2=x^3$ and $x^2y=yx^2$ for all x, y, in S. Show that S can be written as the union of seven pairwise disjoint semigroups and that seven is maximal.

SOLUTIONS OF ADVANCED PROBLEMS

An Arithmetic Inequality

5326 [1965, 915; 1966, 902]. *Proposed by C. S. Venkataraman and R. Sivaramakrishnan, Trichur, India*

If $\sigma_k(n)$ denotes the sum of the kth powers of the positive divisors of a positive integer n and $\tau(n)$ is the number of positive divisors of n, prove that

$$\frac{\sigma_k(n)}{\tau(n)} \geqq \sqrt{n^k}.$$

III. *Solution by E. S. Langford, U. S. Naval Postgraduate School.* Using the methods developed in our solution of E 1749 [1966, 84], we can show that

$$\sigma_k(n)/\tau(n) \geqq n^{k/2} + (n^{k/2} - 1)^2/\tau(n),$$

with equality if and only if n is a prime or the square of a prime. Since $\tau(n) \leqq n$ with equality only when $n=2$, it follows that

$$\sigma_k(n)/\tau(n) \geqq n^{k/2} + (n^{k/2} - 1)^2/n,$$

with equality if and only if $n=2$.

Generators and Relations for Cyclic Groups

5327 [1965, 915]. *Proposed by J. H. Conway, Gonville and Caius College, Cambridge, England*

Show that the group generated by five generators a, b, c, d, e, subject only to the relations $ab=c$, $bc=d$, $cd=e$, $de=a$, $ea=b$, is cyclic of order 11.

I. *Solution by J. A. Wenzel, University of Kansas.* All generators can be expressed as words in a and b. Thus $a=babab^2ab$ and $b=ab^2aba=ab^2ab^2abab^2ab$. From the last equation we get the identity $i=ab^2(ab^2aba)b^2a=ab^5a$. Now $a^2=babab^2aba=bab\cdot b$ and $a=ai=a^2b(bab^2)a^2(bab^2)a=a^2ba^7$. Thus $i=aba^7=a^2ba^6$ and $ab=ba$. Therefore $b=a^5b^8=a^3b^3$ and $i=a^2b^5$. Hence $a^2b^5=a^3b^2$ and $a=b^3$. From this we have $i=b^{11}$.

II. *Solution by R. C. Lyndon, University of Michigan.* Eliminating successively $c=ab$, $d=bab$, and $e=ab^2ab$, we find that the group, G_5, is generated by a and b, with two defining relations, $babab^2ab=a$ and $ab^2aba=b$. We find that $a^2=(babab^2ab)a=bab(ab^2aba)=bab^2$, and hence that $a^5=(bab^2)a(bab^2)=b(ab^2aba)b^2=b^4$. Therefore the element $a^5=b^4$ is central. In view of the automorphism permuting a, b, c, d, and e cyclically, the element $b^5=c^4$ is central. Since b is central, G_5, generated by a and b, is abelian, and it is routine to calculate that its order is 11.

Let G_n denote the corresponding group for general $n=1, 2, \cdots$, and $A_n=G_n/G_n'$. As a module over the integers, with basis $\langle a, b\rangle$, A_n is defined by the relation matrix M^n-I, where $M=\left(\begin{smallmatrix}0 & 1\\ 1 & 1\end{smallmatrix}\right)$. M has eigenvalues λ_1, $\lambda_2=(1\pm\sqrt{5})/2$, whence M^n-I has eigenvalues λ_i^n-1, and A_n has order

$$a_n = |\det(M^n - 1)| = |(\lambda_1^n - 1)(\lambda_2^n - 1)| = |(-1)^n - (\lambda_1^n + \lambda_2^n) + 1|.$$

If $\{f_n\}$ is the Fibonacci sequence 1, 3, 4, 7, 11, 18, $\cdots$, then $a_n = f_n - 1 - (-1)^n$, and $\{a_n\} = 1, 1, 4, 5, 11, 16, \cdots$. We note that, although G_1, G_2, G_4, and G_5 are finite cyclic groups, G_3 is not abelian.

III. *Comment by Harley Flanders, University College, London.* For $n=3$, we have G is $\langle a, b, c\rangle$ with $ab=c$, $bc=a$, $ca=b$, and so G is the (non-abelian) Hamiltonian group of order 8 consisting of the quaternions ± 1, $\pm i$, $\pm j$, $\pm k$. With six generators, one finds, after some computation, that $G=\langle a, b\rangle$ with $a^2ba^2=b$, $b^2ab^2=a$. The homomorphism

$$a \to \begin{pmatrix} 1 & 0 \\ 2 & 1 \end{pmatrix}, \qquad b \to \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

maps G onto an infinite subgroup of the linear group, hence G is infinite in this case.

Also solved by Shair Ahmad, Gerd Baron (Austria), D. A. Blaeuer, J. L. Brennan, Warren Brisley (Australia), R. T. Bumby, C. M. Campbell (Scotland), H. S. M. Coxeter, M. S. Demos, J. F. Dillon, R. R. Erskine, E. W. Ewing, Steven Feigelstock, N. J. Fine, A. W. Fuller (England), M. G. Greening (Australia), E. F. Haeussler, Jr., D. A. Hejhal, W. E. Hoff, J. M. Hood, L. N. Howard, Wilfried Imrich (Austria), Roman Kaluzniacki, Tetsuzo Kimura (Japan), Kenneth Kramer, R. C. Lyness (England), J. G. Mauldon (England), H. M. MacNeille, N. S. Mendelsohn, William Moser, Moshe Mole lekoa (Basutoland), D. K. Pease, Donald Quiring, Ramjilal (India), P. S. Schnare, Donna Seaman, L. W. Shapiro, D. L. Silverman, A. Sinkov, M. F. Smiley, S. A. Smith & D. A. Blaeuer, D. A. Smith, Al Somayajulu, R. G. Stanton, Preston Stein, C. Van de Vyle (Belgium), M. J. Wicks (England), R. S. C. Wong & J. S. W. Wong, John Zolnowsky, and the proposer.

Editorial Notes. (1) In connection with II above, Lyness poses the question as to what additions to the relations $ab=c$, $bc=d$, $\cdots$, $hi=a$, $ia=b$ are necessary in order to generate the cyclic group of order 19 and notes that commutativity is inadequate.

R. T. Bumby observes that the matrix M^n-I actually contains a full description of G_n/G_n'. The theory of elementary divisors yields the fact that $G_n/G_n' \cong Z_a \oplus Z_b$ where a=g.c.d. (entries of M^n-I), $a \mid b$ and $ab=\det(M^n-I)$. A summary of relevant results is:

$$\begin{aligned} G_n/G_n &\cong Z_k \oplus Z_{5k}, && n \equiv 0 \pmod 4 \\ &\cong Z_k \oplus Z_k, && n \equiv 0 \pmod 2 \\ &\cong Z_2 \oplus Z_{2k}, && n \equiv 3 \pmod 6 \\ &\text{is cyclic,} && (n, 6) = 1. \end{aligned}$$

(2) Proofs that G_6 is infinite were provided also by Coxeter and Mendelsohn. Mendelsohn has proved G_7 to be infinite and conjectures, as do Lyndon and Moser, that G_n is infinite and non-abelian for $n \geqq 6$. The papers: (i) N. S. Mendelsohn, *An algorithmic solution for a word problem in group theory*, Can. J. Math., 14 (1964) 509–516 and 15 (1965) 505; (ii) C. T. Benson and N. S. Mendelsohn, *A calculus for a certain class of word problems in groups*, Univ. of Manitoba preprint—give an algorithmic procedure for solving all problems of the given type.

The alternative procedure is to use the Todd-Coxeter enumeration method, counting the cosets of the subgroup generated by b and finding there is only one coset—a method used by Campbell in his solution for $n=5$. In this connection see J. A. Todd and H. S. M. Coxeter, *A practical method for enumerating cosets of a finite central abstract group*, Proc. Edin. Math. Soc., (2), 5 (1936) 34–36; H. S. M. Coxeter and W. O. J. Moser, *Generators and Relations for Discrete Groups*

(Springer, 1964), (see page 8 of this reference for a discussion of G_3); C. M. Campbell, 1965 Dissertation, McGill University.

(3) In Wicks solution ($n=5$), no use is made of inverses or of cancellation laws, and he observes that the semigroup with the given generators and relations is cyclic and of order 11.

Convexity of Function Spaces

5350 [1966, 87]. *Proposed by S. A. Naimpally, Iowa State University*

Menger (Math. Ann., 100 (1928) 75–163) defined a convex metric space (X, d) to be one for which, corresponding to each pair of distinct points $p, q \in X$, there exists a point $r \in X$ different from p, q such that $d(p, q) = d(p, r) + d(r, q)$, and showed that if X is complete then p, q are joined by a metric segment $\overline{pq}$, i.e. by a subset of X which is isometric to a segment of the real line of length $d(p, q)$. Further, if this metric segment is unique we call X a *strongly convex* space.

If (X, d) is a strongly convex complete metric space with a bounded metric d, and F is the function space of all continuous self-mappings of X with metric ρ, where for $f, g \in F$, $\rho(f, g) = \sup_{p \in X} d(f(p), g(p))$, then show that F is convex. Is F convex when X is merely convex?

Solution by M. D. Mavinkurve, Siddharth College, Bombay, India. We assume compactness of the space (X, d). This, however, does not affect the counter-example which follows. Let f, g be in (F, ρ). Define h on X so that $h(x)$ is the point which bisects the unique metric segment $\overline{f(x)g(x)}$. h is continuous. For let $x_n \to x$ so that $f(x_n) \to f(x)$, $g(x_n) \to g(x)$. We write $a_n, b_n, c_n, a, \cdots$ for $f(x_n)$, $g(x_n)$, $h(x_n)$, $f(x)$, $\cdots$. Since distance is a continuous function of both its variables and f, g are continuous, we have $d(a_n, b_n) \to d(a, b)$. Therefore

$$d(a_n, c_n) = \tfrac{1}{2} d(a_n, b_n) \to \tfrac{1}{2} d(a, b) = d(a, c).$$

Since $|d(a, c_n) - d(a_n, c_n)| \leqq d(a, a_n) \to 0$, we have also $d(a, c_n) \to d(a, c)$, and similarly $d(b, c_n) \to d(b, c)$.

Let p be a cluster point of the sequence $\{c_n\}$ whose existence is assumed. Let a subsequence $\{c_{n_k}\}$ converge to p, so that $d(a, c_{n_k}) \to d(a, p)$. It follows that $d(a, p) = d(a, c)$. In the same way, $d(b, p) = d(b, c)$ and $d(a, p) + d(p, b) = d(a, b)$. By the uniqueness of the segment $\overline{ab}$, $p = c$. Therefore the sequence $\{c_n\}$ in the compact space X has a unique cluster point c, and it follows that $c_n \to c$.

That the hypothesis of strong convexity is essential is shown by the following example. Let X be the unit circle in the plane with the distance d measured along the minor arc. (X, d) is a complete, convex metric space but not strongly convex due to the presence of diametrically opposite points. Let f be the constant mapping of the circle on to a point a of the circle and let g be the continuous mapping which takes each point into the diametrically opposite point. Then $\rho(f, g) = \pi$. The convexity of F implies existence of continuous h such that $\rho(f, h) = \alpha$, $\rho(h, g) = \pi - \alpha$ where $0 < \alpha < \pi$. The image under h is a closed arc contained in a closed arc of length 2α with center at a. The restriction of h to this image is like a continuous map of a closed segment of the reals into itself and has

therefore a fixed point. It follows that $\rho(h, g)=\pi$ and $\rho(f, h)+\rho(h, g)=\pi+\alpha$, a contradiction.

Also solved by R. O. Davies (England), Erhard Heil (Germany), Donald Quiring, and the proposer.

All of the solutions for the first part above made use of compactness or local compactness of (X, d).

The Ring of Power Series

5351 [1966, 87]. *Proposed by R. G. Buschman, State University of New York at Buffalo*

Louis Brand (this MONTHLY, 71 (1964) 719–728) discusses a convolution ring S for sequences of complex numbers and its extension into a division algebra. It is not difficult to see that for a sequence $A \in S$ with $a_0=0$, the equation $X^2=A$ has no solution.

(i) Show that $X^2=A$ has a solution in S if and only if the index of the first nonzero element of the sequence $A \neq 0$ is even.

(ii) Hence, for the Fibonacci sequence, $Y^2=\{f_n\}$ has no solution, but $X^2=\{f_{n+1}\}$ has a solution. Extract the square roots of this "left-shifted" Fibonacci sequence.

(iii) Indeed, show that $\{i^{-n}P_n(i/2)\}^2=\{f_{n+1}\}$, where the P_n are the Legendre polynomials.

Solution by Harsh Pittie, Swarthmore College. The ring in question, S, is just the ring of formal power series around zero over the complex field. Now, if A is any such power series, with nonzero constant term, then A has a square root in the ring. For, let $A=\sum_0^\infty a_n z^n$. Define $B=\sum_0^\infty b_n z^n$ by $b_0=\sqrt{a_0}$ (take either of the two roots), $b_1=a_1/2b_0$, and recursively,

$$b_n = \left(a_n - \sum_0^{n-1} b_{n-k}b_k\right) \Big/ 2b_0.$$

It is easy to check that $B^2=A$. Suppose that P is any such power series with first nonzero term $p_n z^n$. Then

$$P = z^n(p_n + p_{n+1}z + \cdots) = z^n Q^2$$

by the above. We recall from elementary analysis that z^n has a square root in the ring if and only if n is even; hence P does if and only if n is even.

The left-shifted Fibonacci sequence ($f_{n+2}=f_{n+1}+f_n$, $f_1=1, f_2=2$) is generated by

$$F(z) = (-z^2 - z + 1)^{-1} \equiv \sum_0^\infty f_{n+1}z^n.$$

Then $\sqrt{F(z)}$ also has a Taylor expansion around zero. Letting $z=iw$, we see that

$$\sqrt{F(z)} = (w^2 - 2(i/2)\, w + 1)^{-1/2} = \sum_{n=0}^{\infty} P_n(\tfrac{1}{2})w^n = \sum_{n=0}^{\infty} (i^{-n}P_n(i/2))z^n.$$

Also solved by L. Carlitz, D. A. Hejhal, Douglas Moore & Sidney Spital, B. L. D. Thorpe, and the proposer.

Thorpe proves that $X^n = A$ has a solution in S if and only if the index of the first nonzero element of the sequence A is divisible by n.

Subdirect Sums of Ore Domains

5352 [1966, 88]. *Proposed by Kwangil Koh, North Carolina State University*

A ring is called duo if every one-sided ideal of the ring is a two-sided ideal. If R is a ring let R^{Δ} be the nonsingular ideal of R. Prove that for a duo ring R the following conditions are equivalent:

(i) $R^{\Delta} = (0)$.

(ii) R is isomorphic to a subdirect sum of Ore domains. (A ring is said to be an Ore domain if it is an integral domain and any pair of nonzero right ideals and left ideals has a nonzero intersection.)

(iii) R is isomorphic to a subring of a direct sum of division rings.

Solution by F. L. Sandomierski and V. C. Cateforis, University of Wisconsin. The following simple lemmas will be used:

LEMMA. 1. *The epimorphic image of a duo ring is a duo ring.*

Let R, S be rings, R a duo ring, f a ring homomorphism of R onto S. If J is a right (left) ideal of S, then $f^{-1}(J)$ is a two-sided ideal of R and hence so is $J = f(f^{-1}(J))$ of S.

LEMMA 2. *An integral domain R, which is a duo ring, is an Ore domain.*

Let I and J be left (right), hence two-sided, nonzero ideals of R. Then $0 \neq IJ \subseteq I \cap J$.

LEMMA 3. *If a ring R is prime and duo, then R is an Ore domain. (A ring is prime iff $AB = (0)$ for ideals A and B of R, implies $A = (0)$ or $B = (0)$.*

If $x \in R$ set

$$(x)_R = \{xr + xm \mid r \in R,\ m \text{ an integer}\},$$

$$R^{(x)} = \{tx + nx \mid t \in R,\ n \text{ an integer}\},$$

both two-sided ideals of R. Now let x and y be nonzero elements of R. If $xy = 0$ then $R^{(x)(y)}R = (0)$ and this implies $x = 0$ or $y = 0$ since R is prime. Hence $xy \neq 0$, and R is an integral domain. By Lemma 2, R is an Ore domain.

Proof of the problem. (i) implies (ii). We first show that R contains no nilpotent ideals $\neq (0)$: suppose $I^2 = (0)$ with I an ideal in R. Since $R^{\Delta} = (0)$, I is not large in R. A simple application of Zorn's lemma shows now that there exists an ideal J in R maximal with respect to the property that $I \cap J = (0)$ and further $I + J$ is large in R. Now $(I+J)I \subseteq I^2 + JI = JI \subseteq I \cap J = (0)$. Since $I + J$ is large in R and $R^{\Delta} = (0)$, it follows that $I = (0)$. We now use Theorems 4.25 and 4.27

(pp. 71–72) of [1] to conclude that R is isomorphic to a subdirect sum of prime rings. (ii) now follows from Lemmas 1 and 3.

(ii) implies (iii). By (ii) R is isomorphic to a subring of the (complete) direct sum of a family $\{S_\alpha | \alpha \in A\}$ of Ore domains. It is well known, e.g. [2], that the quotient ring (classical) of an Ore domain is a division ring. Thus if Q_α is the quotient ring of S_α for each α then R is isomorphic to a subring of the direct sum of $\{Q_\alpha | \alpha \in A\}$ and we have (iii).

(iii) implies (i). Suppose R is (isomorphic to) a subring of the direct sum of a family $\{Q_\alpha | \alpha \in A\}$ of division rings. Let I be a large ideal of R and x an element of R such that $xI = (0)$. If π_α for each α is the usual projection of the direct sum onto the component Q_α then $\pi_\alpha(I) = (0)$ for each α for which $\pi_\alpha(x) \neq 0$, since multiplication in the direct sum is component-wise. Let $[x]$ denote the ideal of R generated by the element x. Then $\pi_\alpha([x]) = (0)$ for each α for which $\pi_\alpha(x) = 0$ and it follows that $I \cap [x] = (0)$. But I is large in R, so that $x = 0$ and thus $R^\Delta = (0)$.

1. Neal H. McCoy, *The Theory of Rings*, New York, 1964.
2. O. Ore, *Linear equations in non-commutative fields*, Ann. Math., 32 (1931) 463–477.

Also solved by Harsh Pittie, Surjeet Singh (India), and the proposer.

Singh and the proposer used the fact that the ring as characterized in the problem is also semi-prime.

Semi-simple Subdirectly Irreducible Duo Rings

5353 [1966, 88]. *Proposed by Kwangil Koh, North Carolina State University*

A subdirectly irreducible duo ring which is semi-simple is a division ring.

Solution by C. C. Lindner, Coker College, Hartsville, S. C. Let R be a ring satisfying the given conditions. In view of problem 5227 [1965, 918] we need only show that R is primitive. Since R is subdirectly irreducible, the intersection of the nonzero ideals of R is not $\{0\}$. Since R is semi-simple, the radical of R is

$$\cap\{(0: M) \mid M \text{ an irreducible module}\} = \{0\},$$

so that $(0: M) = 0$ for some M, for otherwise we would have an intersection of nonzero ideals equal to $\{0\}$. Hence M is a faithful irreducible R-module and so R is primitive.

Also solved by V. C. Cateforis, R. A. Howland, Harsh Pittie, Surjeet Singh (India), and the proposer.

Elements of Nonzero Order

5354 [1966, 88]. *Proposed by B. R. Toskey, Seattle University*

An exercise in Fuchs, *Abelian Groups* (ex. 26, p. 36) is to prove that if G is an R-module, where R is a (commutative) domain of integrity, then the elements of nonzero order form a submodule. Is the statement true if R is a noncommutative integral domain?

Solution by Kwangil Koh, North Carolina State University. There exists an integral domain R and R-module G such that the elements of nonzero order of G do not form a submodule. Let F be a field and $R=F[x, y]$, the ring of polynomials over F in two indeterminates x and y such that $xy-yx\neq 0$. Then R is an integral domain and $xR\cap yR=(0)$. Hence by problem 5059 [1962, 1012] there must exist an R-module G whose elements of nonzero order do not form a submodule.

Also solved by G. A. Heuer, Harsh Pittie, and the proposer.

Elements in the Commutator Subgroup of a Group

5355 [1966, 88]. *Proposed by P. M. Weichsel, University of Illinois*

Let G be a group. Show that u is an element of the commutator subgroup of G if and only if there exist elements $g_1, \cdots, g_k$ in G such that $u=g_1g_2\cdots g_k$ and $1=g_kg_{k-1}\cdots g_1$.

I. *Solution by J. V. Ralston, Jr., Stanford University.* Let C be the commutator subgroup of G, and H be the set of all elements u of G which have the given form. C is generated by the commutators $xyx^{-1}y^{-1}$ of G, and H is obviously a subgroup of G. Hence, to show $C\subseteq H$, it suffices to show that a given commutator can be written as an element u of H. In fact, given $xyx^{-1}y^{-1}$, let $g_1=x$, $g_2=yx^{-1}$, $g_3=y^{-1}$. Then $u=g_1g_2g_3$, and $g_3g_2g_1=1$, and so forth.

Conversely, let $u\in H$. Then $u=g_1\cdots g_k\cdot g_1^{-1}\cdots g_k^{-1}$ since $g_1^{-1}\cdots g_k^{-1}=(g_1\cdots g_k)^{-1}=1$. Let ψ be the canonical homomorphism from G onto G/C. Then

$$\psi(u)=\psi(g_1)\cdots\psi(g_k)[\psi(g_1)]^{-1}\cdots[\psi(g_k)]^{-1}$$

which is the identity of G/C since G/C is Abelian. Thus $u\in C$ because C is the kernel of ψ.

II. *Solution by E. A. Schreiner and Dalton Tarwater, Western Michigan University.* Any commutator $aba^{-1}b^{-1}=a(ba^{-1})b^{-1}$ is of the given form, as is any product of commutators.

Conversely, if $u=g_1\cdots g_k$ and $g_kg_{k-1}\cdots g_1=1$, then $u=u\cdot 1=g_1\cdots g_kg_1^{-1}\cdots g_k^{-1}$ is in the commutator subgroup. This is clear if $n=1$ or $n=2$. Otherwise

$$u=(g_1g_2g_1^{-1}g_2^{-1})(g_2g_1)g_3\cdots g_n(g_2g_1)^{-1}g_3^{-1}\cdots g_n^{-1}$$

and the proof follows by induction on n.

Also solved by D. R. Arterburn, Anders Bager (Denmark), F. S. Brenneman, Warren Brisley (Australia), R. T. Bumby, A. J. D'Aristotle, R. O. Davies (England), Stan Dick & Mike Orleck & Preston Stein, W. G. Dotson, Bruce Feldmeyer, N. Ganesan (India), J. D. Gillam, M. G. Greening (Australia), D. M. Hancasky, Geoffrey Kandall, Irving Katz, J. B. Kelly, C. P. Lawes, Arthur Lieberman, Steve Ligh, C. C. Lindner, M. D. Mavinkurve (India), Ka Menehune, D. E. Standish, Art Steger, R. J. Tondra, Kenneth Yanosko, Peter Yff (Lebanon), and the proposer.

"Positive" Subsets of a Real Field

5356 [1966, 88]. *Proposed by K. E. Whipple, Auburn University, Alabama*

Suppose that F is a subfield of the real numbers and P is a subset of F having the following properties:

(1) P is closed with respect to addition and multiplication.

(2) If x belongs to F, then only one of the following is true, (i) $x=0$, (ii) $x\in P$, (iii) $-x\in P$.

Must P be the set of positive numbers in F?

I. *Solution by R. B. Hardin, Jr., Wayne State University.* This is essentially example 2, p. 14, in Gelbaum and Olmstead, *Counterexamples in Analysis*, where the negative answer is obtained by observing that $P=\{a+b\sqrt{2}\,|\,a,\ b \text{ rational},\ a-b\sqrt{2}>0\}$ satisfies the requirements and $-\sqrt{2}\in P$.

II. *Solution by C. C. Lindner, Coker College, Hartsville, S. C.* The problem can be restated as follows: are there subfields of the real numbers having more than one ordering? The answer to this form of the question is yes, since any subfield of the form $R(\theta)$, where R is the field of rationals and θ any transcendental real number, has a noncountable number of distinct orderings. (See N. Jacobson, *Lectures in Abstract Algebra*, vol. III, p. 272.)

Also solved by Anders Bager (Denmark), R. D. Berlin, R. O. Davies (England), W. G. Dotson, Jr., Roy Dubisch, Charles Green, D. A. Hejhal, G. A. Heuer, J. E. Homer, Jr., R. J. Hursey, Jr., Sheila M. Kaye, Israel Kleiner, H. E. Lahmann (Germany), C. W. Leininger, Arthur Lieberman, T. H. Massengale, J. G. Mauldon (England), L. F. Meyers, A. R. Moore, Vishnu Parkash (India), Howard Schwartz, W. R. Scott, D. L. Silverman, Surjeet Singh (India), L. A. Stein, Preston Stein, J. E. Wilkins, Jr., and the proposer.

Editorial Note. Davis comments that the answer to the problem is in the affirmative if F is assumed to contain the square roots of all positive elements. See, e.g., van der Waerden, *Modern Algebra*, vol. 1, 2nd ed., pp. 225 ff (cited by Hursey). See also Dubisch, *Introduction to Abstract Algebra*, ex. 5, pp. 46–47.

A Sum of Multiplicative Elements

5357 [1966, 88]. *Proposed by David Rearick, University of Colorado*

If n is a positive integer, let $f(n)$ denote the number of ways of expressing n as a product of two relatively prime positive integers, disregarding order. Let $\nu(n)=(-1)^{r(n)}$ where $r(n)$ is the number of distinct prime divisors of n. Show that

$$\sum_{n=1}^{\infty}\frac{\nu(n)f^3(n)}{n^2}=\frac{7}{8}.$$

Solution by Addison Fischer, Student, Washington Irving High School, Clarksburg, W. Va. If $n=p_1^{a_1}p_2^{a_2}\cdots p_k^{a_k}$, then $f(n)=2^{k-1}=2^{r(n)-1}$ (this can be shown in many ways, e.g. by induction on k); we set $f(1)=1$. Hence,

$$\sum_{n=1}^{\infty} \frac{\nu(n)f^3(n)}{n^2} = 1 + \sum_{n=2}^{\infty} \frac{(-1)^{r(n)}2^{3r(n)-3}}{n^2} = \frac{7}{8} + \frac{1}{8}\sum_{n=1}^{\infty} \frac{(-8)^{r(n)}}{n^2}.$$

Since $r(n)$ is an additive function, $(-8)^{r(n)}$ is a multiplicative function, thereby enabling us to transform this sum into a product (over all the primes):

$$= \frac{7}{8} + \frac{1}{8}\prod_p \sum_{k=0}^{\infty} \frac{(-8)^{r(p^k)}}{p^{2k}} = \frac{7}{8} + \frac{1}{8}\prod_p \left(1 - \frac{8}{p^2-1}\right) = \frac{7}{8},$$

since the term with $p=3$ vanishes and hence so does the product. This representation is valid since the product for $p>3$ is absolutely convergent.

Also solved by Anders Bager (Denmark), Robert Breusch, L. Carlitz, P. Gobel (Netherlands), Emil Grosswald, J. B. Kelly, Dan Marcus, Břetislav Novák (Czeckoslovakia), E. W. Trost (Switzerland), and the proposer.

REVIEWS

EDITED BY KENNETH O. MAY, University of Toronto

Materials for review should be sent to Kenneth O. May, American Mathematical Monthly, Department of Mathematics, University of Toronto, Toronto 5, Canada. Correspondence about Reviews will be welcome.

Statement of policy: *Since it is quite impossible to review in detail all the publications of interest to readers of the Monthly, and since full reviews are often delayed until their news value is greatly reduced, we intend in this department to print prompt "telegraphic reviews" of all materials within our field of coverage, which is collegiate mathematics from the junior through the second graduate year. (The first two collegiate years are now covered by the Mathematics Magazine, and reviews of materials at the research level may be found in many journals.) Selected materials will be reviewed again more extensively.*

Statistical Methods. By Stefan Szulc. Translated by J. Stadler. Pergamon Press, L. I. City, New York, 1965. viii+666 pp. $17.50.

Applications in the biological and social sciences.

Mathematics and Politics. By Hayward R. Alker Jr. Macmillan, New York, 1965. 152 pp. $1.50. Not just a "how-to-do-it" book on statistics for political scientists, but an attempt to show how several important ideas in the history of mathematics may increase our understanding of politics. This involves a study of the historical inter-relationship of the two disciplines. S, P.

Basic Statistics with Business Applications. By Richard C. Clelland, John S. deCani, Francis E. Brown, J. Parker Bursk and Donald S. Murray. Wiley, New York, 1966. xvi+708 pp. $11.50. Inspired by recent "drastic revision" of the business education course at the University of Pennsylvania to include a one-year freshman course giving some technical proficiency in calculus and linear algebra and familiarity with simple set-theoretic notions. T (14, following a Freshman course in calculus and elementary linear algebra), S.

Applied Regression Analysis. By Norman Draper and Harry Smith. Wiley, New York, 1966. ix+407 pp. $11.75. Emphasis on "practical application" rather than mathematics. T (16), S, P.

Readings in Mathematical Social Science. Edited by Paul F. Lazarsfeld and Neil W. Henry. S.R.A., Chicago, 1966. 371 pp. $10.50. Papers selected to give a "broad introductory view of the new applications of mathematics to the social and behavioral sciences." P.

The Mathematics of Life Insurance, 2nd ed. By Walter O. Menge and Carl H. Fisher. Macmillan, New York, 1965. vi+189 pp. $6.95. Extensively revised edition of text by Menge and Glover, first published in 1935. T, S, P.

The Use of Mathematics in Economics. Edited by V. S. Nemchinov. M.I.T. Press, Cambridge, Mass., 1965. xxxi+377 pp. $12.50. Contributions by six Soviet economists and mathematicians who use mathematical methods in analyzing and planning a socialist economy. P.

Random Processes and the Growth of Firms, a Study of the Pareto Law. By Josef Steindl. Hafner, New York, 1965. 249 pp. $10.00. P.

Mathematics in the Social Sciences and Other Essays. By Richard Stone. M.I.T. Press, Mass., 1966. xiii+291 pp. $12.00. Reprints of essays 1960–1965, "all illustrations of my belief . . . that mathematical models are necessary both at the theoretical . . . and the applied level." Most examples from economics. Bibliography. S, P.

The Compleat Strategyst, rev. ed. By J. D. Williams, McGraw-Hill, New York, 1966. xvi+268 pp. $6.95. The revised edition of this widely known book, first published in 1954, contains a new chapter on "the pivot method" and a general method for solving matrix games. S, P.

The Geometry of Incidence. By Harold L. Dorwart. Prentice-Hall, Englewood Cliffs N. J., 1966. xvii+156 pp. $6.25.

This is a delightful little book written for the purpose of reviving an interest in projective geometry. Some acquaintance with analytic geometry will provide adequate background for reading it with profit. It is not a textbook, as it contains no exercises, but it should find its way to reading lists for those who have an interest in mathematics but have not taken a formal course in projective geometry.

After a carefully motivated introduction of ideal elements in the plane, the author discusses line curves and defines homogeneous point and line coordinates. He then presents an analytic formulation of the real projective plane and discusses two models of that plane and the principle of plane duality. The definition of a plane configuration leads to the study of three famous theorems of projective geometry, those of Pappus, Desargues, and Pascal. Analytic proofs are given, and applications are mentioned.

The final chapter contains a brief introduction to the general projective plane and to finite projective planes. The relationship of Latin squares and perfect difference sets to finite planes is indicated as an area of present day research.

The definition given for a perfect difference set is not the usual one, and, in fact, it is not satisfied by any of the sets listed except 1, 2, 4. There are relatively few typographical errors.

The book is written in an entertaining style, somewhat informal, but dignified. Appropriate historical material enlivens the exposition. Extensive notes and an excellent bibliography guide the interested reader to further and deeper study of many of the topics considered.

JANET MCDONALD, Vassar College

Algebra. By Serge Lang. Addison-Wesley, Reading, Mass., 1965. 508 pp. $12.75.

Columbia's Professor Lang, in this first year graduate text, manages to achieve an admirable and needed blend of several seemingly divergent facets of algebra. The book roughly follows the "classical" Artin-van der Waerden order, but the inclusion of newer results, especially in the chapter on representations of finite groups, greatly extends and amplifies the presentation. Lang spices the book liberally with homological notation. Fortunately, the use of diagrams is not forced, and lengthy diagram chasing is avoided. The early introduction of categories and functors provides a good basis for the extension of theorems to various topics. As with most modern works, the influence of Bourbaki is also strongly felt. The word "warning" even replaces Bourbaki's "Z." Lang has done a presentable job of editing from Bourbaki's massive publications on linear algebra and representations. Many of the chapters are independent and the use of key repetitions allows the instructor a good deal of flexibility.

The book, however, may be a little too sophisticated for the audience for which it is intended. Perhaps in the interest of being somewhat encyclopedic in a limited space, long lists of definitions are presented with few relevant examples or applications. Proofs are perhaps too abbreviated and often might be better motivated. A less parsimonious use of commas might make the text more readable. Nevertheless, all these peccadillos are amply offset by Professor Lang in a timely, complete, and illuminating work.

A. G. BRANDSTEIN, University of Connecticut

Lie Groups for Physicists. By R. Hermann. Benjamin, New York, 1966. vii+193 pp. $12.50 (domestic).

Homogeneous spaces of Lie groups, especially symmetric spaces, and their application to physics, is the main theme of this book which is intended for " . . . physicists interested in the possible application of Lie group theory to elementary-particle theory. . . . " It is *not* a book for beginners.

The first quarter of the book is devoted to reviewing and illustrating some of the basic ideas and facts in Lie group theory. Among the group theoretic concepts treated in the remaining portion of the book one finds: homogeneous vector bundles, induced representations, the universal enveloping algebra, and limits and contractions of Lie groups and algebras. These notions provide a backdrop for viewing such topics as: Wigner's representations of the Poincaré (i.e. the inhomogeneous Lorentz) group, the Klein-Gordon equation, the Dirac equation, and some of the classical asymptotic formulas for the special functions in mathematical physics. Additional topics treated

from a group theoretic point of view include the hydrogen atom and strong coupling theory, perturbation theory, gauge groups and supermultiplet theory, and Gell-Mann's formula.

Mathematical ideas are clearly presented, most of the proofs are omitted or sketched and a good bibliography is included. Typographical and other editorial-type errors occur on an average of one per every three and one-half pages, and the proof that every derivation of a semi-simple Lie algebra is inner (Lemma 4–5, p. 17) is in error.

D. J. STERLING, Bowdoin College

Structural Models: An Introduction to the Theory of Directed Graphs. By Frank Harary, Robert Z. Norman, and Dorwin Cartwright. Wiley, New York, 1965. viii+415 pages. $9.95.

The authorities who award prizes for attractive books should not miss this one. The authors have instilled a beguiling quality which invites browsing. The writing is readable, conversational even. Social scientists, for whom the book is principally intended, will find easy access to several basic and readily applicable sectors of digraph theory. The typography, design, and diagrams contribute admirably to the book's appeal and usefulness. Each chapter is launched by an appropriate, often waggish, quotation. How better to introduce "Limited Reachability" than by "Ill can he rule the great, that cannot reach the small."

Key concepts in this treatise are directional duality, connectedness, digraphs and boolean operations for matrices, condensations of digraphs, limited reachability, removal of lines and of points, blocks, acyclic digraphs, tournaments, balance, and networks. Definitions are usually well motivated, and conclusions are usually illustrated by examples and applications. The organization of the theory is formal: eighty-odd "principal theorems" are stated in a convenient reference list. The examples are remarkably varied, including ordering by likes and dislikes, competition of commodities, communication and rumor networks, sociometric choices, coalitions, status in an organization, games, consistency in paired comparisons, cost geodetics in networks. Exercises are numerous and varied in difficulty.

An important book which is attractive, useful, and generally accurate may have a few serious deficiencies. The reviewer's principal criticism is that so very many technical terms are included. The glossary, which helps overcome the disadvantage of a large vocabulary, contains some one hundred eighty items. It is not surprising, then, that many theorems are in the form of a list of equivalent propositions. Multiplicity of concepts may well enhance the usefulness of the book, but at times, happily not often, even the sprightly style of the authors does not entirely conceal the tediousness of theorems which contain no surprises. A minor suggestion for revision: since the preface promises illustrations from scaling theory, propositional logic, and cognitive structure, those items should appear by name in the index.

The reviewer has used this book as a source for a seminar for non-majors and for an independent reading project for a major. It has been distinctly satisfactory in both capacities.

D. E. CHRISTIE, Bowdoin College

Vectors. By Parry Moon and Domina Eberle Spencer, D. Van Nostrand, Princeton, 1965. 352 pages. $8.95

This book gives an introduction to vector and tensor analysis, primarily for engineers and physicists. After several introductory chapters which define tensors, vector and tensor algebra is introduced, finally specializing to the dot and cross product of vectors in three-space. Covariant derivative, gradient, divergence and curl are studied in connection with vector-valued functions. Some differential geometry is given, including the

Frenet formulas, Green's theorem in Euclidean three space, and Stoke's theorem in two-space. Among other physical applications, there is a chapter devoted to retarded potentials. There is a list of problems at the end of each chapter.

The distinctive feature of this book occurs in the introductory chapter, where the terms *holor* and *merate* are introduced. A *holor* is defined as a "mathematical entity built up of several independent elements." A *merate* seems to be defined as one of the independent elements of the holor. From these puzzling definitions, the authors infer that a holor can be expressed by different arrays of numbers in different coordinate systems, and the idea of transformation from one coordinate system to another is introduced. Tensors are defined to be holors which transform properly, and from this point on, the book proceeds along quite conventional lines.

This book makes it clear that tensor is a term that requires a good mathematical definition. Non-mathematicians have frequently had great success with objects such as the Dirac δ-function, which were not described as mathematical objects. But the concept of tensor as described by physicists has always been somewhat mysterious, and this book does little to dispel the mystery. It is possible that the word holor is intended to mean the same thing as *quantity*, as used by J. A. Schouten (*Ricci Calculus*, 2nd. ed. Springer-Verlag, Berlin, 1954). If so, the reader will find a fairly concise definition of the term in that book.

Two additional criticisms are local in character, but may hint at a fundamental logical difficulty. On page 20 of *Vectors*, we find a fairly reasonable definition: "Two holors are equal if and only if each corresponding pair of merates is equal." But on page 120, we find "But the equality of holors implies merely their equality in one coordinate system, . . . ". On page 81 is found the phrase "an *infinitesimal* change in space coordinates," as contrasted to "a *finite* change in space coordinates." One wonders what meaning is intended by "infinitesimal change."

It is clear that vectors and tensors are extremely difficult to present, even to students who are fairly conversant with mathematics. It will require a strong mixture of mathematical ability, physical insight and instinct for teaching to produce an ideal textbook on vectors for a non-mathematical audience.

E. B. LEACH, Case Institute of Technology

Selected Papers of Norbert Wiener. By Norbert Wiener, M.I.T. Press, Boston, Mass., 1964. 453 pp. $12.50.

On November 26, 1964, Norbert Wiener would have been 70 years old, and it was intended that this volume appear as a celebration of his birthday. Unhappily, he died in March of that year.

This book is a collection of some of Wiener's outstanding contributions to the field of mathematics and these are chosen mainly from his work prior to 1932. In particular, his classic works on Generalized Harmonic Analysis and Tauberian Theorems take up more than half the volume.

In general, the work carried out in these papers contributed significantly not only to much of Wiener's subsequent work but also to much of modern mathematics.

We are indebted to Y. W. Lee, N. Levinson, and W. T. Martin for bringing together for us in one volume this collection of Wiener's work. In reading its pages, we are once again struck by the magnitude of his vision, interests and perception. Here we see fully displayed not only his deep interest in the applications of mathematics but also his consummate mastery of mathematics.

The volume contains a foreword by Martin, an introduction in depth by Levinson and an analysis by Lee of Wiener's contributions to linear theory and nonlinear theory in engineering. These are excellent and will help the reader set Wiener's work into its proper historical context.

H. H. GOLDSTINE, IBM

Finite Graphs and Networks, An introduction with applications. By R. G. Busacker and T. L. Saaty. McGraw-Hill, New York, 1965. 294 pp. $11.50.

The tremendous renaissance of graph theory and combinatorics stems from their wide applicability. The first book ever written on graph theory, *per se*, was the classic by König [1]. This was followed after two decades by three more modern books [2, 3, 4]. A book [5] with the identical title as the English translation of Berge [2] consists of a collection of papers presented in 1963 at a symposium held in Czechoslovakia. The next book on graph theory [6] was written primarily for a readership of social scientists, and is the only book devoted entirely to directed graphs. Two books [7, 8] have been written on networks.

1. D. König, *Theorie der endlichen und unendlichen Graphen.* Leipzig, 1936, reprinted Chelsea, New York, 1950.

2. C. Berge, *Théorie des graphes et ses applications.* Dunod, Paris, 1958; English translation, Methuen, London, 1962.

3. O. Ore, *Theory of graphs.* Amer. Math. Soc. Colloq. Publ., 38 (1962).

4. ———, *Graphs and their uses.* Random House, New York, 1963.

5. M. Fiedler, editor. *Theory of graphs and its applications.* Czechoslovak Academy of Sciences, Prague and Academic Press, New York, 1964.

6. F. Harary, R. Norman, and D. Cartwright, *Structural models: an introduction to the theory of directed graphs.* Wiley, New York, 1965.

7. L. R. Ford, Jr. and D. R. Fulkerson, *Flows in networks.* Princeton Univ. Press, Princeton, 1962.

8. C. Berge and A. Ghouila-Houri, *Programmes, jeux, et réseaux de transport.* Dunod, Paris, 1962; English translation, Methuen, London, 1965.

Thus it is natural to ask: what does the book under review have that the other books don't have? The book is divided into two parts: I. Basic Theory, II. Applications. The first chapter of Part II, "A variety of interesting applications," includes material not available in any other one book and constitutes the main contribution. These applications include references to economics and operations research, combinatorial problems, puzzles and games, physical systems, communication networks, electrical networks, organic chemistry, statistical mechanics, genetics, cybernetics, sociometry, disarmament, linguistics, and Markov chains. As the authors indicate, these topics are not developed in detail, but rather are presented as indications of applications which must still be studied from original sources. Since this book provides an opportunity for scholars in the above-mentioned fields to observe examples of the use of graph theoretic methods, it will stimulate further interest in graph theory.

A few words of criticism. It seems inappropriate for the dust cover of a book on graph theory to display a spiral galaxy, when there are so many pretty graphs that could be used. The location of the references at the end of each chapter (and sometimes at the end of sections) is quite inconvenient. No two books on graph theory agree in terminology or notation; the present book is no exception. There are, of course, the usual assortment of misprints.

FRANK HARARY, The University of Michigan

Introduction to Calculus and Analysis, Vol. I. By R. Courant and F. John. Interscience-Wiley, New York, 1965, xxiii+661 pp. $10.50.

Courant's *Vorlesungen über Differential und Integralrechnung* (1927) and its modified English editions (1934, 1937), have exerted a deep and beneficial influence on the teaching of calculus in the United States. The many admirers of these books will welcome this new text written to satisfy the specific needs of American students with the same emphasis on applications and on intuitive understanding. As the authors say: "Mathematics presented as a closed, linearly ordered, system of truths without reference to

origin and purpose has its charm and satisfies a philosophic need. But the attitude of introverted science is unsuitable for students who seek intellectual independence rather than indoctrination; disregard for applications and intuition leads to isolation and atrophy of mathematics. It seems extremely important that students and instructors should be protected from smug purism." It is to be hoped that this book will help to reverse the direction in which the wind is now blowing.

The explanation of many topics previously treated has been amplified, clarified and made more precise. There is considerable new material and much of the older material has been promoted from fine print. The language of mapping has been introduced. But the authors do not hesitate to speak of dependent and independent variables or use the expression "y is a function of x." As they say, "This locution is used freely in the sciences, but some of the more pedantic texts avoid it. There is no point in hampering ourselves by an undue concern for hair-splitting 'precision' when it has no relation to the substance."

A supplementary volume "Problems in Calculus and Analysis" has been prepared by Albert A. Blank which reprints the problems in the text and adds hints and solutions. Exercises of a more routine character have also been included, with answers and solutions when needed.

This volume is concerned with functions of a single variable. "A Sketch of the Theory of Functions of Several Variables" contained in the previous text is omitted.

While the content of this book bears a marked resemblance to the previous English editions, this is indeed a new book. We confine ourselves to noting the most striking differences.

Chapter 1. Introduction. (*118 pp.*) This excellent chapter is an expanded and reorganized treatment of the Continuum of Numbers, The Concept of Function, The Elementary Functions and The Theory of Limits. It includes new material on Mathematical Induction and Lipschitz and Hölder Continuity.

Chapter 2. (*81 pp.*) *The Fundamental Ideas of the Integral and Differential Calculus.* The earlier material has been amplified and rearranged so that, for example, the mean value theorem for integrals precedes that for derivatives and the logarithmic and exponential functions are moved forward.

Chapter 3. (*122 pp.*) *The Techniques of Calculus* combines the earlier Chapters 3 and 4 with relatively little change, but there is an improved treatment of the substitution rule for integrals, a new section on the differential equation satisfied by $\sin x$ and $\cos x$, and an explanation of O and o notation.

Chapter 4. (*115 pp.*) *Applications in Physics and Geometry* contains an expanded and elegant treatment of curves and their included areas. Material on vectors in the plane is new.

Chapter 5. (*40 pp.*) *Taylor's Expansion.* The major change is the inclusion of an appendix on interpolation.

Chapter 6. (*28 pp.*) *Numerical Methods and Chapter 7.* (*60 pp.*) *Infinite Sums and Products* contain improvements in detail.

Chapter 8. (*61 pp.*) *Trigonometric Series* includes much new supplementary material (Weierstrass Approximation Theorem, Fejer's Approximation, Parseval's Relation, Gibbs' Phenomenon, Bernoulli Polynomials, Generating Function, Euler-Maclaurin Summation Formula).

Chapter 9. (*16 pp.*) *Differential Equations for the Simplest Types of Vibration.* Little change.

This book is a welcome addition to mathematical literature where the word "literature" is singularly appropriate. Volume II is eagerly awaited.

D. E. RICHMOND, Williams College

Methods of Matrix Algebra. By Marshall C. Pease, III. Academic Press, New York and London, 1965. xviii+406 pp. $13.75.

Starting from basic principles, the book presents a rather comprehensive development of matrix algebra and its use in a variety of physical applications. The concept of a matrix is introduced as a means of describing linear mappings of vector spaces. The general theory is developed from the concept of eigenvectors and chains of generalized eigenvectors, and carried through to such items as the Jordan canonical form, functions of a matrix, the matricant, and dyad expansions. Special topics include the solution of equations involving singular and rectangular matrices, projectors, and the direct product and Kronecker sum. The theory is illustrated by applying matrix methods to periodic systems of differential equations, to a discussion of the stability of such systems, to electromagnetic theory, and to stochastic processes. Special attention is drawn to a chapter on "The Improper Inner Product."

The book is written with the purpose of making available to the physical scientist and engineer some of the more sophisticated techniques of matrix algebra. Except for a few basic theorems, however, such as the existence of an inverse, most proofs are carried through in a reasonably detailed mathematical fashion. In some cases, the verbal discussions involving physical reasoning for certain situations did not enlighten me, although I must confess I am not in the intended audience. For example, in discussing transmission lines it does not help to have the Manley-Rowe relations invoked when I have never heard of them.

I have rather mixed feelings regarding the book as a text. As the preface mentions, the author has in mind someone near the graduate level in physics. I would expect that, in addition, the student who also has had an introductory course in matrix algebra would profit most from this text, and would be able to use it fruitfully as a reference book. If used as a text, I would guess that there is more than enough material for a full year course. Problems, without answers, are given at the end of each chapter. Relatively few misprints were noted and all these were of a trivial character.

A. B. FARNELL, General Dynamics/Convair

Linear Integral Equations. By S. G. Mikhlin. (Translated from the 1959 Russian edition under auspices of Hindustan Publishing Corp., Delhi). Gordon and Breach, New York, 1960. vii+223 pp. $9.50.

Mikhlin's book has been reviewed several times in its Russian, English and German versions. It is a sound and useful text along classical lines, with occasional illuminations of old topics. But the present translation is so poor as to be downright misleading and even incomprehensible. It should not be put into the hands of young people.

A. T. LONSETH, Oregon State University

A First Course in Partial Differential Equations. By Hans F. Weinberger. Blaisdell, Waltham, Mass., 1965. ix+446 pp. $12.75.

The main purpose of this book is to teach the techniques of solving partial differential equations by the method of separation of variables. Unlike most books on the subject, however, Professor Weinberger's book stresses the importance of concepts of real analysis, and he does this naturally and incisively. Any student interested in mathematics and applied mathematics should find this a valuable book.

As an introduction to partial differential equations, the book is an outstanding contribution. Included is the use of characteristics and energy methods, and

a self-contained treatment of functions of a complex variable. An unusual feature is the careful discussion of the evolution of a physical model into a mathematical model, using the vibrating string as an example.

Finally, it should be mentioned that Professor Weinberger's writing style makes the book a pleasure to read.

The chapter headings are: I. The one-dimensional wave equation; II. Linear second-order partial differential equations in two variables; III. Some properties of elliptic and parabolic equations; IV. Separation of variables and Fourier series; V. Nonhomogeneous problems; VI. Problems in higher dimensions and multiple Fourier series; VII. Sturm-Liouville theory and general Fourier expansions; VIII. Analytic functions of a complex variable; IX. Evaluation of integrals by complex variable methods; X. The Fourier transform; XI. The Laplace transform; XII. Approximation methods.

A. D. MacGillivray, State University of New York at Buffalo

Linear Representation of the Lorentz Group. By M. A. Naimark. Pergamon Press, New York, 1964. 447 pp. $14.50.

The linear representations of the Lorentz group are, at present, of great importance in physics, and the author remarks that he wrote the present work as a book for physicists. In any case, the book is a very valuable contribution to the mathematical textbook literature. The style is simple and lucid. The mathematical tools are reduced to the minimum necessary to prove the theorems concerning the Lorentz group, and some theorems from Functional Analysis are proved in nine appendices. At the same time, many generalizations of the results proved are mentioned, and appropriate references are given. Formulas are spelled out in great detail. The three dimensional orthogonal group, the proper and the complete Lorentz group are studied carefully, and their finite dimensional representations are given before the treatment of the infinite dimensional representations which takes up about one half of the book. The last 100 pages are dedicated to an investigation of the invariant equations as far as it can be carried out, and several of the important unsolved problems in this area are mentioned.

W. Magnus, New York University

Powell, Lehigh University, have been appointed Assistant Professors; Dr. Ronald Jacobowitz, University of Arizona, has been appointed Associate Professor; Associate Professor T. K. Boehme, University of California at Santa Barbara, has been appointed a Visiting member of the staff; Professor Carl Boyer, Brooklyn College, will be the Rose Morgan Professor for the fall semester.

University of Missouri: Dr. Keewhan Choi, Cornell University, has been appointed Assistant Professor of Statistics; Professor H. D. Brunk has been appointed Senior Lecturer in Statistics at the University College of Wales in Aberystwyth.

Northeast Louisiana State College: Mr. L. T. Bennett, Oklahoma State University, and Mr. Charles Smith, Oklahoma State University, have been appointed Assistant Professors; Assistant Professor Edward Anders has been appointed Head of the Mathematics Department at Arkansas State College; Mrs. Rosemary Hamner has been promoted to Assistant Professor; Assistant Professor D. R. Bedgood has been promoted to Associate Professor.

Associate Professor Robert Bridgman, Mansfield State College, has been promoted to Professor.

Associate Professor L. E. Claborn, Cornell College, is on leave-of-absence for one year of study at the University of Illinois.

Mr. Sen Fan, Brown University, has been appointed Associate Professor at Morningside College.

Dr. R. E. Huddleston, Texas Christian University, Fort Worth, has been appointed Research Associate at the Institute for Fluid Dynamics and Applied Mathematics at the University of Maryland.

Assistant Professor J. A. Pavelcak, Merrimack College, has been appointed Director of the Computing Center.

Assistant Professor H. J. Reschovsky, University of Connecticut, has been promoted to Associate Professor.

Dr. R. E. Roth, St. Bonaventure University, has been appointed Professor of Statistics and Director of the Computer Center, State University College, Geneseo.

Dr. F. M. Morgan, Clark School, New Hampshire, died on June 28, 1966. He was a charter member of the Association.

Professor Emeritus Tibor Rado, Ohio State University, died on December 28, 1965. He was a member of the Association for 35 years.

Mr. A. A. Warntz, Syracuse University, died on January 8, 1966. He was a member of the Association for five years.

BOOKS FOR ASIAN STUDENTS

Technical and scientific books and journals are needed in the schools of Asia. The Asia Foundation's Books for Asian Students Program will distribute your donations to these schools free of charge. Books must be dated 1955 or later and be in good condition. Journals must be in runs of five years or more dated 1946 or later. Shipments and inquiries may be made at any time to the program at 451 Sixth Street, San Francisco, California 94103. Donations to The Asia Foundation are tax deductible.

MATHEMATICAL ASSOCIATION OF AMERICA

Official Reports and Communications

APRIL MEETING

OF THE MARYLAND-DISTRICT OF COLUMBIA-VIRGINIA SECTION

The annual Spring meeting of the Maryland-District of Columbia-Virginia Section of the MAA was held at the College of William and Mary, Williamsburg, Virginia, on April 30, 1966. Dr. Samuel Saslaw, Chairman of the Section, presided. There were 74 persons in attendance, including 70 members of the Association.

At the business meeting the following officers were elected: Chairman, Professor Thomas L. Reynolds, College of William and Mary, Williamsburg, Virginia; Vice Chairmen, Professor Joseph Milkman, U. S. Naval Academy, Annapolis, Maryland and Professor Raymond W. Moller, Catholic University of America, Washington, D. C.; Secretary, Professor George N. Trytten, University of Maryland, College Park, Maryland; Treasurer, Professor Stanley B. Jackson, University of Maryland, College Park, Maryland.

The following program was presented:

1. *The bouncing ball does come to rest*, by W. J. Young, Emory and Henry College.
2. *Application of a differential technique to a difference system*, by A. L. Deal, III, Virginia Military Institute.
3. *A theorem on additive arithmetical functions*, by R. L. Robinson, U. S. Army.

4. *On trigonometric matrices and their applications*, by G. J. Etgen, Headquarters, N.A.S.A., Washington, D. C.

5. *An example of optimal control*, by G. S. Jones, Institute for Fluid Dynamics and Applied Mathematics, University of Maryland, (invited address).

6. *On the original Malfatti problem*, by Michael Goldberg, Bureau of Naval Weapons, U. S. Navy, Washington, D. C.

7. *Plane symmetry groups*, by C. M. Makepeace, National Civil Defense Computer Facility, Olney, Maryland.

8. *Statistical validation of mathematical computer routines*, by Carl Hammer, UNIVAC, Washington, D. C.

G. N. TRYTTEN, *Secretary*

APRIL MEETING OF THE METROPOLITAN NEW YORK SECTION

The twenty-fifth annual meeting of the Metropolitan New York Section of the MAA was held on April 30, 1966, at the Polytechnic Institute of Brooklyn. There were 105 persons present, of whom 75 were members of the Association. Abraham Schwartz of the City University of New York was elected Governor of the Section; the terms of the other officers of the Section extend to the 1967 annual meeting. It was decided that next year, at the 1967 meeting, a Vice President for Junior Colleges would be elected, in addition to the established office of Vice President for High Schools.

The program of the meeting was as follows:

1. *Topics in topological algebra*, by Terrell Gardner, Queens College.

The continuous character groups of the additive reals, the circle group, and the additive integers (usual topologies) were derived, topologized as old friends, and their character groups acknowledged, leading to the statement of Pontrjagin's duality theorem. A brief discussion of commutative Banach algebras included a statement of the Stone-Weierstrass and Gelfand representation theorems. The existence of non-commutative analogues for C^+-algebras was mentioned. Finally, the p-adic fields were described, and their utility in number theory remarked.

2. *CUPM Panel on college teacher preparation*, by Leonard Gillman, University of Rochester.

The recently formed Panel is charged with examining all phases of college teacher preparation. It is recommending more summer institutes and the creation of several new types of institutes to help present teachers, and it is considering special graduate programs for the preparation of new teachers.

3. *Report of the Chairman of the Contest Committee and presentation to winners of the Metropolitan New York Section Contest*, by C. T. Salkind, Polytechnic Institute of Brooklyn.

4. *Report of the Section Governor and of the Director of the Speakers Bureau*, by J. N. Eastham, Queensborough Community College.

5. *Treasurer's report*, by Aaron Shapiro, Midwood High School.

6. *Round table discussion—"Transition in Mathematics from High School to College."* Chairman of the discussion was Meyer Jordan, Brooklyn College. Speakers on the topic were: Benjamin Bold, Stuyvesant High School; Freeman Cope, Queens College; George Crossman, New York City Board of Education; Harry Ruderman, Hunter High School; Jules Russell, Polytechnic Institute of Brooklyn; Abraham Schwartz, The City College.

The meeting concluded with a showing of the Calculus Film Project of the Committee on Educational Media.

MARY HAGEN, *Secretary*

APRIL MEETING OF THE SOUTHWESTERN SECTION

The annual meeting of the Southwestern Section of the MAA was held at the University of New Mexico, Albuquerque, on April 1–2, 1966. There were 78 persons including 55 members of the Association in attendance. Section Chairman J. Mayer, University of New Mexico, presided.

Two speakers were invited to address the section. Professor E. Dyer, Rice University, lectured on "Quasi topology" and Professor I. N. Herstein, University of Chicago, lectured on "Rings of quotients." The keynote address was given at the Friday evening banquet by Professor R. B. Crouch, New Mexico State University.

A panel moderated by M. Norris, Sandia Corporation, discussed "The future structure of mathematics departments and related questions." Panel members were department chairmen J. R. Blum, University of New Mexico; H. Cohn, University of Arizona; R. B. Crouch, New Mexico State University; E. D. Nering, Arizona State University; L. J. Paige, University of California at Los Angeles.

A second panel on "The CUPM proposal for the training of mathematics teachers in the secondary schools" was moderated by R. J. Wisner, New Mexico State University. Panel members were W. T. Guy, Jr., University of Texas; A. P. Hillman, University of New Mexico; C. E. Little, Northern Arizona University; D. E. Myers, University of Arizona; and W. Scarborough, Albuquerque Council of Teachers of Mathematics.

The following officers were elected: Chairman, D. E. Myers, University of Arizona; Vice-Chairman, R. J. Wisner, New Mexico State University; Secretary-Treasurer, S. T. Kao, University of New Mexico.

The following papers were presented:

1. *On minimal Hausdorff spaces*, by J. R. Porter, New Mexico State University.
2. *Non-commutative local rings*, by M. Lomanitz, New Mexico Institute of Mining and Technology.
3. *A measure of axial symmetry for convex sets*, by Bro. B. A. deValcourt, St. Michael's College.
4. *New divisors of Mersenne numbers by evaluation of certain quadratic forms*, by E. Karst, University of Arizona.

E. L. WALTER, *Secretary-Treasurer*

RECIPROCITY AGREEMENT WITH SOCIÉTÉ MATHÉMATIQUE DE BELGIQUE

Since January 1962, the Association has had a reciprocity agreement with Société Mathématique de Belgique under which MAA members living in the United States or Canada may become members of the Société by paying only one-half of the regular dues. Effective with 1967, this half rate has been increased to 150 Belgian francs or $3 U. S. This fee includes a subscription to the quarterly BULLETIN of approximately 500 pages per year.

MAA members who wish to become members of the Société under the reciprocity agreement should write to Professor Guy Hirsch, 317 Avenue Charles Woeste, Bruxelles, Belgium.

TO OUR READERS: ZIPCODING OF ADDRESSES

In order to qualify for the second class mail rate, MAA has had to append zip code numbers to all addresses to which the MONTHLY is mailed. This has required the retyping of many address plates which in turn has led to the possibility of errors.

We will be very grateful therefore if you will examine the address on the wrapper of your copy of the MONTHLY and notify the Buffalo MAA office of any errors. We will ourselves make all necessary corrections eventually, but the correcting process will be accelerated if our readers will cooperate.

HARRY M. GEHMAN, *Executive Director*

CALENDAR OF FUTURE MEETINGS

Forty-eighth Summer Meeting, University of Toronto, Toronto, Ontario, Canada, August 28–30, 1967.

Fifty-first Annual Meeting, San Francisco, California, January 25–27, 1968.

ALLEGHENY MOUNTAIN, West Virginia University, Morgantown, West Virginia, May 6, 1967.

ILLINOIS, University of Illinois, Urbana, May 12–13, 1967.

INDIANA, Wabash College, Crawfordsville, Spring 1967.

IOWA, Drake University, Des Moines, April 21, 1967.

KANSAS, Fort Hays State College, Hays, April 22, 1967.

KENTUCKY, Murray State University, Murray, Spring 1967.

LOUISIANA-MISSISSIPPI, Jung Hotel, New Orleans, Louisiana, March 4–5, 1967.

MARYLAND-DISTRICT OF COLUMBIA-VIRGINIA

METROPOLITAN NEW YORK

MICHIGAN, University of Michigan, Ann Arbor, March 18, 1967.

MINNESOTA

MISSOURI, Northeast Missouri State Teachers College, Kirksville, April 29, 1967.

NEBRASKA, University of South Dakota, Vermillion, May 6, 1967.

NEW JERSEY

NORTHEASTERN Mt. Allison University, Sackville, New Brunswick, June 23–24, 1967.

NORTHERN CALIFORNIA, University of California, Davis, February 4, 1967.

OHIO, Ohio State University, Columbus, April 22, 1967.

OKLAHOMA-ARKANSAS, Northeastern State College, Tahlequah, Oklahoma, March-April, 1967.

PACIFIC NORTHWEST, University of Montana, Missoula, June 16–17, 1967.

PHILADELPHIA, University of Delaware, Newark, November 18, 1967.

ROCKY MOUNTAIN, Western State College of Colorado, Gunnison, May 1967.

SOUTHEASTERN, Florida Presbyterian College, St. Petersburg, Florida, March 31-April 1, 1967.

SOUTHERN CALIFORNIA, San Diego State College, San Diego, March 11, 1967.

SOUTHWESTERN, University of Arizona, Tucson, March 31-April 1, 1967.

TEXAS, Austin College, Sherman, April 14–15. 1967.

UPPER NEW YORK STATE, State University College, Plattsburgh, May 20, 1967.

WISCONSIN, St. Norbert College, DePere, May 6, 1967.

FUTURE MEETINGS OF OTHER ORGANIZATIONS

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, New York, New York, December 26–31, 1967.

AMERICAN MATHEMATICAL SOCIETY, Toronto, Ont., Canada, August 28–September 1, 1967.

AMERICAN SOCIETY FOR ENGINEERING EDUCATION, Michigan State University, June 19–23, 1967.

ASSOCIATION FOR COMPUTING MACHINERY, Sheraton-Park, Washington, D. C., August 29–31, 1967.

CENTRAL ASSOCIATION OF SCIENCE AND MATHEMATICS TEACHERS, Chicago, November 23–25, 1967.

INSTITUTE OF MATHEMATICAL STATISTICS

NATIONAL COUNCIL OF TEACHERS OF MATHEMATICS, Convention Center, Las Vegas, Nevada, April 16–20, 1967.

OPERATIONS RESEARCH SOCIETY OF AMERICA, New York Hilton Hotel, May 31-June 2, 1967.

PI MU EPSILON

SOCIETY FOR INDUSTRIAL AND APPLIED MATHEMATICS, Shoreham Hotel, Washington, D.C. June 12–15, 1967 (Symposium on Applied Probability and Fluid Dynamics).

New . . . Authoritative . . . Highly Teachable

CALCULUS AND ANALYTIC GEOMETRY, Second Edition

ABRAHAM SCHWARTZ, The City College of the City University of New York

As in the first edition, this text for the introductory calculus course begins with chapters on the differential and integral calculus which rest on an intuitive basis rather than an abstract one.

March 1967 992 pp. $11.95 tent.

INTRODUCTION TO NUMBER THEORY

JAMES E. SHOCKLEY, Virginia Polytechnic Institute

This text was written for a one semester course in number theory for mathematics majors or for mathematics education majors. The text contains a good deal of expository material, and it does not treat proofs as tersely as many other texts.

March 1967 256 pp. $6.75

A FIRST COURSE IN ABSTRACT ALGEBRA

HIRAM PALEY and PAUL M. WEICHSEL, both of the University of Illinois

1966 334 pp. $8.95

A SEMINAR ON GRAPH THEORY (Athena Series)

FRANK HARARY, University of Michigan

This is a book on graph theory that is the result of a seminar held at the University of London in 1963.

April 1967 128 pp. $6.00 tent.

HARMONIC ANALYSIS

by

LYNN H. LOOMIS

Notes by Ethan Bolker from the 1965 MAA Cooperative Summer Seminar at Bowdoin College. About 400 pages. Paper cover.

Copies at $3.00 each postpaid may be ordered from:

Mathematical Association of America
SUNY at Buffalo (University of Buffalo)
Buffalo, New York 14214

New and Recent Books from Prentice-Hall . . .

APPLIED DIFFERENTIAL EQUATIONS, 2nd Edition, 1967, *by Murray R. Spiegel, Rensselaer Polytechnic Institute.* "Spiegel's book is outstanding for its attempts at unified treatments of many topics, for its very good selection of exercises, and for its clarity in presenting techniques for solution of differential equations. . . . This book remains what it always was: one of the best of its type. . . . The additional material on numerical methods is very welcome. The material on Wronskians is of great theoretical importance and helps to clarify the concept of linearly independent solutions of differential equations." *From a Pre-Publication Review. January 1967, approx. 384 pp., $9.95*

MODERN ELEMENTARY STATISTICS, 3rd Edition, 1967, *by John E. Freund, Arizona State University.* While retaining the highly teachable, lucid aspects of the two previous editions, the new Third Edition has been almost completely rewritten. Its objectives, however, remain the same: to acquaint beginning students in the biological, social, and physical sciences with the fundamentals of modern statistics. Most of the illustrations and exercises are new. Dr. Freund has further increased his emphasis on statistical inference and added extensive material on nonparametric tests. There is a wholly new chapter on probability. *January 1967, 432 pp., $9.25*

LINEAR TRANSFORMATIONS AND MATRICES, *by F. A. Ficken, New York University.* A new text presenting the basic theory of finite-dimensional real and complex linear spaces. For students taking a first "conceptual" course. The material has been class-tested by the author for over two years before final publication. *January 1967, 398 pp., $10.50*

INTEGRATED ALGEBRA AND TRIGONOMETRY: WITH ANALYTIC GEOMETRY, 2nd Edition, 1967, *by Robert C. Fisher, The Ohio State University, and Allen D. Ziebur, State University of New York at Binghampton.* A thorough revision of one of the most successful pre-calculus mathematics texts published. (Over 158,000 copies sold of previous edition.) The unifying theme of the text is the concept of the function and its graph. New to this edition are the introduction of the language and notation of sets, and the treatment of analytic geometry. The problem lists have been increased and improved in quantity and improved in quality. Includes color illustrations. *January 1967, approx. 448 pp., $8.95*

INTRODUCTORY COMPLEX ANALYSIS, *by Richard A. Silverman, formerly of the Courant Institute of Mathematical Sciences of New York.* A basic senior or first year graduate course in Complex Variable Theory and its applications. Completely self-contained text requires the student to have a background in advanced calculus. Presents a thorough treatment of elementary functions, especially polynomials and rational functions, with separate chapters on harmonic functions, conformal mapping and analytic continuation. Numerous worked-out examples are included in this text to help the student acquire basic technique. *January 1967, 372 pp., $8.50*

INTRODUCTION TO CONTEMPORARY ALGEBRA, *by Marvin L. Tomber, Michigan State University.* Dr. Tomber's new book is an introduction to algebra based on the structure of algebra. His underlying theme is the rational development of algebra as a fundamental human discipline. An informal development of algebra from the axioms of algebra. "An excellent text and well written. Tomber has an interesting style coupled with lucid proofs." *From a Pre-Publication Review. January 1967, 448 pp., $7.95*

CALCULUS AND ANALYTIC GEOMETRY, 2nd Edition, 1965, *also by Robert C. Fisher and Allen D. Ziebur.* The second edition of this popular text offers an accurate, understandable introduction to calculus and analytic geometry. At the end of the course, the freshman should have a good grasp of the essential nature of the subject and should be able to express himself in current notation. The text has been completely rewritten, but the overall coverage, objectives and unifying themes remain the same. *1965, 768 pp., $11.25*

MATRICES AND TRANSFORMATIONS, *by Anthony J. Pettofrezzo, The Florida State University.* Presents the basic concepts of matrix algebra first in an intuitive framework and then in a more formal atmosphere. A variety of interpretations and applications of the terms and operations considered are included. Dr. Pettofrezzo emphasizes the role of matrices as an algebraic structure and the applications of matrix algebra to geometry. *1966, 133 pp., $3.95*

NEW FROM HOLDEN-DAY

Plane Geometry and Its Groups
By HEINRICH W. GUGGENHEIMER, University of Minnesota. Based on the generation of motions by reflections, this new book revitalizes the study of elementary geometry within the framework of modern mathematics. Drawings are a major tool.
February. 300 pp. $9.00 (est.)

Problems and Solutions in Mathematical Physics
By Y. CHOQUET-BRUHAT, Faculté des Sciences de Paris. Trans. by C. PELTZER & ed. by J. J. BRANDSTATTER. Covers linear algebra and analysis; function spaces and differential and integral operators. January. 336 pp. $9.00 (est.)

An Introduction to Sequences, Series, and Improper Integrals
By O. E. STANAITIS, St. Olaf College. Introduces the beginner to fundamental concepts that form a firm basis for theory and application in the sciences and engineering. February. 224 pp. $7.75 (est.)

Challenging Mathematical Problems with Elementary Solutions, II
By A. M. YAGLOM and I. M. YAGLOM. Trans. by JAMES MCCAWLEY, JR. Rev. & ed. by BASIL GORDON. Original problems for high school and college students as well as mathematics teachers. April. 210 pp. Cloth $5.95, Paper $3.95

Introduction to Probability and Statistical Decision Theory
By GEORGE HADLEY. A clearly written basic text for students who have not studied calculus as well as those who have. Many realistic problems emphasize applications in business and industry. February. 500 pp. $10.75 (est.)

Introductory Calculus
By STOUGHTON BELL, J. R. BLUM, J. VERNON LEWIS, and JUDAH ROSENBLATT, University of New Mexico. Provides science and engineering students with immediate applications in concurrent courses, and social sciences, humanities, and business students with a survey of the subject. 336 pp. $8.50

Modern University Calculus
By STOUGHTON BELL, J. R. BLUM, J. VERNON LEWIS, and JUDAH ROSENBLATT, University of New Mexico. A careful and complete exposition of calculus of one and several variables, this new text provides a firm foundation for more advanced mathematics. 974 pp. $11.75

Elementary Partial Differential Equations
By PAUL W. BERG and JAMES L. MCGREGOR, Stanford University. 472 pp. $11.75

Homology Theory: A First Course in Algebraic Topology
By SZE-TSEN HU, University of California, Los Angeles. 260 pp. $11.00

Introduction to Contemporary Mathematics
By SZE-TSEN HU, University of California, Los Angeles. 206 pp. $7.95

Introduction to Modern Elementary Mathematics
By LADIS D. KOVACH, Pepperdine College. 264 pp. $7.75

Measure and the Integral
By HENRI LEBESGUE. Trans. by Scripta Technica. Ed. with a biographical essay by KENNETH O. MAY, University of Toronto. 216 pp. $6.95

HOLDEN-DAY, INC. 500 Sansome St., San Francisco, Calif. 94111

MAJOR TEXTS FROM MACMILLAN

TRIGONOMETRY: AN ANALYTIC APPROACH
By Irving Drooyan and Walter Hadel, both of Los Angeles Pierce College
1967, approx. 384 pages, prob. $5.50

CALCULUS: Part I

By EDWIN E. MOISE, *Harvard University.*

This text for first-year courses in elementary calculus is available in a complete edition and in two parts. *Part I* treats exponentials, logarithms, and trigonometric functions, and assumes *some,* but not a great deal of, prior knowledge of these topics. Ideas such as that of a coordinate system in a plane and mathematical induction are explained from the beginning. Nearly all ideas are introduced intuitively before being formalized, and figures are used freely in the exposition.

The book is, nevertheless, theoretically thorough in the sense that every topic introduced is eventually treated logically and exactly. There is a steady rise in the maturity level at which ideas are presented. Various abstract ideas are discussed at times when they are needed. Problems were composed by the author and are designed to teach the subject.

498 pp. 529 illus. $8.95

CALCULUS: Part II

By EDWIN E. MOISE, *Harvard University.*

Part II treats the calculus of several variables. Among the topics covered are infinite series, the discussion of which strongly emphasizes term-wise integration and differentiation and the differential equations which characterize the elementary functions of classical analysis. Discussions of linear algebra and solid analytic geometry with vectors, and a conventional short introduction to functions of several variables are also included.

Multiple integrals are stressed as the conceptually natural formulation of geometric and physical ideas, and the material on differential equations mainly emphasizes the real domain.

In Press.

CALCULUS: Complete

By EDWIN E. MOISE, *Harvard University.*

In Press.

ALGEBRAIC STRUCTURES

By SERGE LANG, *Columbia University.*

This book is designed for use as a text in modern algebra. Together with the author's *Linear Algebra,* it constitutes a curriculum for an algebra program addressed to undergraduates. Although the present book is self-contained logically, it is perhaps advisable to take the linear algebra course *before* being introduced to the more abstract notions of groups, rings, and fields, and the systematic development of their basic abstract properties. Where overlap exists between this book and *Linear Algebra,* such as on groups of matrices and rings of endomorphisms, the emphasis is quite different.

173 pp. $6.95

INTRODUCTION TO TRANSCENDENTAL NUMBERS

By SERGE LANG, *Columbia University.*

The theory of transcendental numbers consists in determining the transcendence and algebraic independence of numbers obtained as values of classical functions, suitably normalized. This advanced text examines all of the several variations of the one main method of this theory. Applications range from a very elementary setting (concerning the function e^t), to rather sophisticated contexts involving abelian functions and automorphic functions.

105 pp. $7.50

INTRODUCTION TO DIOPHANTINE APPROXIMATIONS

By SERGE LANG, *Columbia University.*

The aim of this book is to illustrate by significant special examples three aspects from the theory of diophantine approximations: first, the formal relationships which exist between various counting processes and functions entering into the theory; second, the determination of these functions for numbers which are given as classical numbers; and third, certain asymptotic estimates holding almost everywhere (e.g. the Khintchine theorems and the Leveque-Erdös-Schmidt theorems).

83 pp. $6.75

An introduction to probability in paperback

DISCRETE PROBABILITY

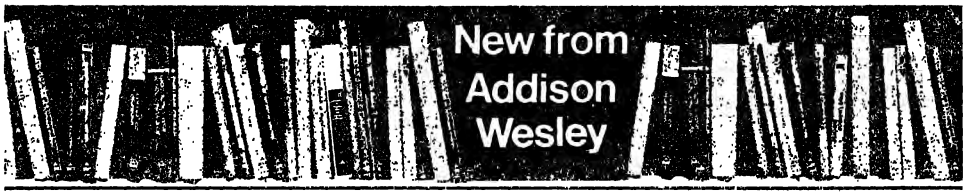
R. A. GANGOLLI
and DONALD YLVISAKER, University of Washington

This book is written for a first course in probability theory. In a mathematics major's program it is appropriate for a course at the sophomore or junior level and provides the necessary foundation for a course in probability and statistics. Also, for students of business, biological sciences, social sciences, or engineering, it can be used to establish the background for a course in statistical methodology. Suitable for a one-quarter or one-semester course, it is also adaptable as a supplementary textbook.

Harbrace College Mathematics Series — *Publication: March*
240 pages, $4.50 (probable)

Algebraic topology for undergraduates

ALGEBRAIC TOPOLOGY
An Introduction



WILLIAM S. MASSEY, Yale University

Written specifically for a one-semester course for advanced undergraduates or beginning graduate students, this text provides a systematic introduction to algebraic topology. It presupposes only a knowledge of elementary point set topology and group theory, and uses standard mathematical language and notation so that the student need not learn a new set of symbols. An Epilogue introduces the more difficult aspects of topology encountered in later courses. Some 60 airbrush and line drawings illustrate the text.

Harbrace College Mathematics Series — *Just published*
256 pages, $8.75

Harcourt, Brace & World, Inc.
New York / Chicago / San Francisco / Atlanta

MATHEMATICS FOR LIBERAL ARTS

By MORRIS KLINE, *New York University.*

Intended for liberal arts and terminal students, this book is a revision and abridgement of the author's *Mathematics: A Cultural Approach.* This revision aims to meet special needs: courses for students who should have a little more review and drill on elementary concepts and techniques, courses for elementary school teachers, and one-semester twelfth-year high school or college courses.

The book offers a review of high school algebra and geometry and a selection of topics from trigonometry, analytic geometry, projective geometry, calculus, non-Euclidean geometry, other algebras, statistics and probability.

In Press.

MATHEMATICS FOR ELEMENTARY TEACHERS: AN INTRODUCTION

By G. CUTHBERT WEBBER, *University of Delaware.*

Intended for elementary school and in-service teachers, or as a supplement to content and methods courses for elementary school personnel, this book lays a foundation for both present-day and traditional courses. The text discusses the mathematics which underlies mathematical topics taught in elementary school curricula, tying together arithmetic ideas usually treated as unrelated topics. In Press.

ELEMENTARY CALCULUS FROM AN ADVANCED VIEWPOINT

By GEORGE B. THOMAS, JR., *Massachusetts Institute of Technology,* JOHN K. MOULTON, *Brookline High School, Massachusetts,* and MARTHA ZELINKA, *Weston High School, Massachusetts*

This text grew out of a series of lectures given to high school teachers of advanced placement calculus, and is intended to provide a deeper understanding of elementary calculus. The main purpose of the book is to show the structure of elementary calculus and its analytical foundations. Theoretical ideas are carefully explained and motivated, and applied to particular problems. In Press.

MATRICES AND LINEAR TRANSFORMATIONS

By CHARLES G. CULLEN, *University of Pittsburgh.*

The first five chapters of this book on linear algebra comprise a one-term text for science, engineering and mathematics students which covers those topics most frequently encountered in applications. Only a first course in calculus and analytic geometry is required. Aimed at the sophomore-junior level, the text approaches the subject from the matrix theory point of view rather than from the more abstract approach using linear transformations.

227 pp. $8.95

INTRODUCTION TO ANALYTIC FUNCTIONS

By WILFRED KAPLAN, *University of Michigan.*

The present book is designed to provide an elementary introduction to functions of complex variables and their applications, for senior and graduate students of science and engineering. The text is based directly on Chapter Nine of the author's *Advanced Calculus,* and also includes a completely new chapter on analytic functions of several complex variables, coverage rarely made accessible at this level.

212 pp. 78 illus. $7.95

INTRODUCTION TO LINEAR ANALYSIS

By DONALD L. KREIDER, *Dartmouth College,* ROBERT G. KULLER, *Wayne State University,* DONALD R. OSTBERG, *State University of New York at Buffalo,* and FRED W. PERKINS, *Dartmouth College.*

This book, which assumes a background in calculus, is designed to serve as an introductory text in applied analysis for students of science and engineering. It covers much of the traditional material, however it also treats topics which are of importance in present day mathematics. The concept of linearity is emphasized and used as a unifying thread which ties together the treatment of topics often presented in an isolated manner. Conceptual understanding is stressed throughout.

THE SIGN OF EXCELLENCE

TWO TEXTS FROM MACMILLAN

Modern Calculus With Analytic Geometry, Volume I

By A. W. Goodman, University of South Florida

This first of a two-volume set is outstanding for its rigorous approach to single-variable calculus, and for its clarity and teachability. All of the theorems of the calculus are rigorously proved, but ample discussion is included so that the student can both follow the proof and understand the need for giving it in the particular manner selected. The text covers functions of a single variable. Volume II will cover multivariable functions.
1967, approx. 832 pages, prob. $10.95

Analytic Geometry and The Calculus

By A. W. Goodman

This book is designed to be used by mathematics majors, science majors, and engineering students. The presentation is generally modern in approach, introducing vectors early and using them wherever possible. Because the study of the calculus requires a thorough understanding of mathematical induction, inequalities, and determinants, the author includes a chapter on each of these topics in the appendix. Answers are provided to all the problems in the book.
1963, 774 pages, $10.50

Write to the faculty service desk for examination copies.

PRINDLE, WEBER & SCHMIDT, INCORPORATED

Publishers • 53 State Street • Boston, Massachusetts 02109

Dear Mathematician:

We would like to take this opportunity to extend to you a cordial invitation to visit our booth and examine our new texts during your visit to Houston for the annual meetings of the A.M.S., A.S.L. and M.A.A.

In addition to our published titles, the following new texts will be on display: Breusch, INTRODUCTION TO CALCULUS AND ANALYTIC GEOMETRY; Hart, INTERMEDIATE MATHEMATICS WITH APPLICATIONS; Johnson, LINEAR ALGEBRA; Swokowski, COLLEGE ALGEBRA; Swokowski, ALGEBRA AND TRIGONOMETRY; Mehlenbacher, FOUNDATIONS OF MODERN MATHEMATICS; and Willerding, MATHEMATICAL CONCEPTS, A HISTORICAL APPROACH.

Of course we would be pleased to send to you, prior to the meetings, examination copies of those texts that you might wish to review for your winter and spring classes.

Cordially,

Prindle, Weber & Schmidt

R.S.V.P.

In mathematics

Count on Wiley books

MATHEMATICAL LOGIC

By STEPHEN COLE KLEENE, *The University of Wisconsin.* A thorough, yet elementary treatment of the propositional and first-order predicate calculi is *immediately* followed by work in logic-proper. The book includes a survey of the exciting newer developments in modern logic—some only a few years old. *1967. Approx. 416 pages. Prob. $10.50.*

CALCULUS: An Intuitive and Physical Approach In Two Parts

By MORRIS KLINE, *New York University.* Instead of rigorous proofs, this book employs intuitive justification of the theorems and techniques of calculus. Geometrical, physical, and heuristic arguments and generalizations are used. Part 1: *1967. Approx. 592 pages. Prob. $9.95.* Part 2: *1967. Approx. 448 pages. Prob. $8.75.*

ADVANCED ENGINEERING MATHEMATICS Second Revised Edition

By ERWIN KREYSZIG, *The Ohio State University.* The new features include simplifications—improvements—and a new chapter on probability and engineering statistics. *1967. Approx. 984 pages. Prob. $11.95.*

THEORY OF ARITHMETIC: Second Edition

By JOHN A. PETERSON, *University of Montana; and* JOSEPH HASHISAKI, *Western Washington State College.* The second edition offers a set-theoretic development of properties of addition and multiplication, and otherwise incorporates valuable suggestions from mathematics educators. *1967. Approx. 338 pages. Prob. $7.50.*

MIXED BOUNDARY VALUE PROBLEMS IN POTENTIAL THEORY

By I. N. SNEDDON, *University of Glasgow.* A North-Holland (Interscience) Book. *1966. 283 pages. $12.75.*

TRANSFORMATION GEOMETRY

By MAX JEGER. A volume in the Mathematical Studies Series. *1966. 143 pages. $3.50.*

JOHN WILEY & SONS, Inc., 605 Third Avenue, New York, N.Y. 10016

ANNOUNCING THE SECOND EDITION

CALCULUS, VOLUME I

One-variable calculus with an introduction to linear algebra

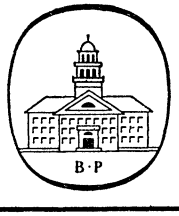
TOM M. APOSTOL

California Institute of Technology

The Second Edition preserves the lively spirit and clear exposition that characterized the First Edition, and also contains a number of signficant improvements.

The book has been divided into smaller chapters, each centering on an important concept. Several sections have been rewritten and reorganized to provide better motivation and to improve the flow of ideas. For example, the mean-value theorems and routine applications of calculus are introduced at an earlier stage. Proofs now follow immediately after discussion of the theorems.

New illustrative examples have been incorporated, applications to physics and engineering have been expanded, and many new and easier exercises have been added.



The last third of Volume I introduces linear algebra with applications to geometry and analysis. Some of this material leans heavily on the calculus for examples to illustrate the general theory. It provides a natural blending of algebra and analysis and helps pave the way for the transition from one-variable calculus to multi-variable calculus discussed in Volume II. Further development of linear algebra will occur as needed in the Second Edition of Volume II to be published later.

As in the First Edition new topics are prefaced by historical introductions included to give the student a sense of participation in the evolution of ideas.

Table of Contents:

Introduction • The Concepts of Integral Calculus • Some Applications of Integration • Continuous Functions • Differential Calculus • The Relation Between Integration and Differentiation • The Logarithm, The Exponential, and The Inverse Trigonometric Functions • Polynomial Approximations to Functions • Introduction to Differential Equations • Complex Numbers • Sequences, Infinite Series, Improper Integrals • Sequences and Series of Functions • Vector Algebra • Applications of Vector Algebra to Analytic Geometry • Calculus of Vector-Valued Functions • Linear Spaces • Linear Transformations and Matrices •

To be published March 1967

Outstanding Texts

CALCULUS WITH ANALYTIC GEOMETRY

JOHN M. H. OLMSTED, *Southern Illinois University*

Stressing clarity, precision, and thoroughness, this modern basic text develops rigorous mathematical thinking while encouraging intuitive motivation. The book follows the historical development of integral calculus before differential calculus, and in the same spirit treats the global concept of uniform continuity before the local concepts of ordinary continuity and limits. In two volumes, illustrated.

Vol. I: 810 pp., $9.50; Vol. II: 655 pp., $7.00

CALCULUS WITH ANALYTIC GEOMETRY

EDWIN J. PURCELL, *University of Arizona*

Rigorous enough to challenge the best student and lucid enough to stimulate the average student, this text stresses the acquisition of an understanding of calculus as well as knowledge of its formulas and techniques. A wide variety of exercises is provided and the principal definitions and theorems are displayed for easy reference.

843 pp., illus., $10.00

ELEMENTARY CONCEPTS OF MODERN MATHEMATICS

FLORA DINKINES, *University of Illinois (Chicago)*

This text offers an accurate, comprehensive presentation of the theory of sets, mathematical logic, and groups, rings, and fields.

Hardbound edition: 457 pp., illus., $6.50

ELEMENTARY THEORY OF SETS	*237 pp., illus., paper, $2.65*
INTRODUCTION TO MATHEMATICAL LOGIC	*122 pp., paper, $1.65*
ABSTRACT MATHEMATICAL SYSTEMS	*97 pp., illus., paper, $1.45*

AN INTRODUCTION TO MATRICES, VECTORS, AND LINEAR PROGRAMMING

HUGH G. CAMPBELL, *Virginia Polytechnic Institute*

This text is designed for use where matrix algebra must be taught to students with a limited mathematical background. Interweaving the concrete and the abstract throughout, equipped with abundant examples and problems, and class-tested, the book is well suited for today's accelerated courses, for teacher-training programs, and for reference.

244 pp., illus., $6.50

MODERN BASIC MATHEMATICS

HOBART C. CARTER, *Mary Washington College of the University of Virginia*
Technically easy but mathematically advanced concepts are introduced throughout this basic text for courses in freshman mathematics. An abundance of stimulating exercises is provided with each section, affording the teacher a wide range of flexibility in regulating the ratio of theory to technique. The text is suitable for a terminal course yet prepares students for intermediate courses.

466 pp., illus., $6.50

PREFACE

The fiftieth anniversary of the founding of the Mathematical Association of America was celebrated at the 1965 Summer Meeting at Cornell University. For an account of this meeting, see this MONTHLY, 72 (1965) 1053–1059 and the frontispiece of the November issue.

As part of this celebration a special program of invited addresses was presented. The texts of these addresses have been collected and are now printed in this Fiftieth Anniversary Issue and are published as a supplement to the MONTHLY.

BRIEF HISTORY OF THE MATHEMATICAL ASSOCIATION OF AMERICA BEFORE WORLD WAR II

ALBERT A. BENNETT, Brown University

1. Introduction. For a few moments you are asked to try to look backward instead of forward. To relive the past is difficult, but the recent centennial of bloody and unglamorous battles of our Civil War have partially acclimatized us to so doing. The backward glance that reduced Lot's wife to the salt of the earth seems to be almost an un-American activity.

It is not in the dull recital of statistics concerning forgotten events, that this our gathering achieves any significance. Rather, it would seem that we are here to memorialize the work of many charter members, largely here nameless, most of whom are gone, including nearly all who played a major role in the founding.

The one thing important about the Mathematical Association of America at this its semicentennial is that it is going strong. It has increased in numbers and activities and in favor with college and public.

2. The Founding. Our Association was founded under especially auspicious circumstances. The many favorable factors were not accidents, nor miracles, nor achieved through serendipity. Some were the end results of a chain of events, not always desired, nor always with the eventual outcome in view. But in large part they were secured through wise planning, tactful compromise, cajoling of the apathetic, courageous facing of pessimists in high places, and unremitting work.

The stories of the Mathematical Association of America and of the American Mathematical Monthly are closely intertwined and present also some curious aspects as to their names, as will be brought out.

Briefly cited, here are some eleven of the special items of initial good augury.

1. The Association had the (for mathematics) phenomenal initial paid individual membership of 1045 (living in 25 of our states), or one per hundred thousand of the national population at the time. It had also initially 52 institutional members.
2. The Association started with many experienced, devoted and distinguished mathematicians at the helm.
3. The Association took over a well established, favorably known journal and one with the same objectives as the Association, as its official organ, a journal with wide collegiate backing, editorially and financially, and whose staff had worked enthusiastically toward this development. This journal, the *American Mathematical Monthly* was continued without break in its general policies, although with notable enrichment.
4. Five semi-autonomous sections were part of the original plan, with generous provision for promptly setting up further future local sections.
5. The phrase "of America" was interpreted from the start to include Canada and indeed the North American Continent.

6. Not only was an annual meeting to be held each winter, but also a regular meeting of the whole Association each summer. One might note in passing that prior to 1945 only one annual meeting was cancelled, that for 1942, during the war, due to stringent travel restrictions, and only two summer meetings, those for 1924 and 1938, the latter in deference to the Semi-centennial Celebration of the American Mathematical Society.
7. Furthermore, these scheduled meetings of the Association were planned to be held successively in various parts of the country.
8. Cooperation with the American Mathematical Society was assured from the start and plans for frequent joint meetings with it and with such organizations as the American Association for the Advancement of Science, the National Council of Teachers of Mathematics, and eventually others were part of the original program.
9. One of the most serious intentions of the founders of our Association was the furtherance of publication of expository articles, monographs or books, on advanced mathematical topics. Toward success in this plan, the founders from the start maintained active cooperation with the management of the Annals of Mathematics, then sponsored by Princeton University, and secured representation by the Association upon its editorial board.
10. To avoid the danger of a self-perpetuating clique, a dual-choice slate for all Association offices was arranged for.
11. The annual dues were instituted at a sub-snob appeal level, thus inviting general support without sacrifice.

The MATHEMATICAL ASSOCIATION, now so vigorous, adopted its present name, as many of you may know, in February 1897. This Association had already been operating, and on an international basis, for several years before that time but under a longer and more restrictive title. Its official organ was established, and with the present title, in 1894 and was published in both New York and London. Later its places of publication were changed to London and Bombay. For indeed, "The Mathematical Association" is and always has been the official title of but one organization, and that, British. Its original objective was primarily the much overdue reform in the teaching of geometry. Its journal is the *Mathematical Gazette*. But enough of that.

The MATHEMATICAL ASSOCIATION OF AMERICA came into being on the last afternoon of 1915. Herbert E. Slaught, a leading, if not indeed the leading organizer of this Association, described in 1930 a dream, "a picture of the celebration in January 1966 of the Fiftieth Anniversary of the founding of the Mathematical Association, with Hedrick, Cairns, Finkel and Slaught, and many others present and in the full bloom of their years."

3. Contemporary Events. This founding was an event, like that of Einstein's announcement, that year, of the general theory of relativity, little noted by the

public. Even as might be expected the sense of mutual unconcern was unruffled. Nothing in the records of the Association might seem to hint that the Great War had been underway in deadly earnest in Europe. And not in Europe alone. Turkey was persecuting the Armenians in Asia Minor. Britain had seized Germany's rich colony in East Africa. Japan had annexed Germany's port on the China Sea. Russia, stretching across Europe and Asia to the Pacific, was committed to its last muzhik to the war effort. Canada was being drained of young man power. But the United States was at peace and with a professed neutrality. In this one felt no sham, no shame. The highest idealism saw eye-to-eye with the frankest economic profit. In 1914 even before Zeppelins were dropping bombs on a bewildered and defenseless London, indeed in the very days that the Triple Alliance and the Triple Entente were declaring mutual war, we opened the Panama Canal to neutral traffic. Although half the world was struggling for sheer existence, we celebrated throughout 1915 the Panama-Pacific International Exposition. The half million who paid admission on the last day of this Fair, had little mind for the roll of distant drums. To be sure, David Starr Jordan, Chancellor of Stanford University, after touring the country, lecturing on the impossibility of a world war, was struggling, *ex post facto*, for peace; and on December the fourth, Henry Ford, with a futile band of enthusiasts and ridiculing newsmen, had sailed to Europe on his Peace Ship, with no previous plan and no subsequent success. Most Americans greeted such rampant idealism with at best a condescending smile.

Politically, the World map of 1915 looked quite otherwise than it does now. Among the late Queen Victoria's 74 descendents (as of 1915), many were among the 78 "reigning sovereigns of Europe" (as phrased in the World Almanac of 1916). Kaiser Wilhelm of the German Empire (long self-styled, the Peace Kaiser) announced his hope of dropping a bomb on each of his two cousins, George V, Emperor (*in absentia*) of India, and Nicholas II, Emperor and absolute autocrat of Russia. And his sentiments were shared by Kaiser Franz Joseph of Austria. Emperors dotted the landscape. Bulgaria had its own Czar. Even among the six nations of Africa, Abyssinia had an emperor who called himself "King of Kings" and claimed direct descent from King Solomon and the Queen of Sheba. His sacred majesty, King George of England could do as well (but less romantically), claiming the biblical King David as an ancestor. He could glory also in the pious title of Defender of the Faith, claimed by right of descent (but hardly by right of logic) from Henry VIII, thus once ennobled by a Pope. Only Japan could do better. As averred at the time in the Encyclopaedia Britannica, the Emperor of Japan traced his lineage by unbroken line of male descent back to Jimmu Tenno, 660 B.C., the only son of the Moon Goddess. Even China, after a couple of decades as a republic, was again briefly an empire.

Later we read in the MONTHLY a few personnel notices of so and so entering the armed forces. Altogether 178 members of the MAA were eventually so listed. It is sobering to realize that already before April 1917, 10,000 German public school teachers were reported as having been killed in the war.

On New Year's Day 1916, few of those Americans, if in condition to think at all, were thinking about involvement in the war which we expected so soon would end. We had not even been informed by President Wilson that we were "too proud to fight." No one had invented the word "camouflage." The unsinkable Titanic had gone down on her maiden trip by what was called an Act of God; but the proud British liner Lusitania had for some years, until May 8, 1915, crossed and recrossed the Atlantic in presumed safety from acts of evil men. Out in the Pacific, the long uninhabited Midway Island now housed a small band of about 40 submarine telegraph cable operators and repairmen. Pearl Harbor was still part of an island Paradise. William Howard Taft, defeated in 1913 for reelection to the U. S. presidency, was president of the benign Asiatic Institute.

If at last we could be pushed into war, Americans would always volunteer in multitudes to defend the Stars and Stripes! Military draft was a European curse, not to be adopted here. The War Risk Insurance had been just established, but not to pay soldiers' widows, only ship owners' losses. The War Department could not entirely ignore the rapid phenomenal advances in the Art of War. President Teddy Roosevelt had only a few years before congratulated Kaiser Wilhelm on his fine army, the only army in Europe ready to fight, and obviously equipped to lick all Europe should such be called for. So Congress had reluctantly permitted the organization in this country of a Military Aviation Branch, but had prudently safeguarded against reckless expansion by insisting that there shall not be more than 15 military aviators. Perhaps to ensure offensive effectiveness, each of the one-man crews could carry an army pistol.

Of course, in 1916, we were immensely proud of our victorious military history. What with the semi-centennials of Civil War dates, and Teddy Roosevelt's flag-waving and the G.A.R. veterans leading every parade—all honor to our brave heroes! Pensions, restricted to those totally disabled incident to military service, amounted to $30 per month to generals down to $8 per month to sergeants and below. This seems hardly munificent; but remember, a man's wool suit, cut tailored to order, cost only from $10 to $20. For the many rich, a diamond of $1\frac{1}{2}$ carat weight could be bought for $139. Some pensioners from the American Revolution were still on the rolls. But with all our national and political enthusiasm, we were learning to be less demonstrative. Already torch light parades were a bit passé. While in 1909, on the Glorious Fourth, 215 were killed and 5092 were reported as hospitalized by fire works, in 1916 these numbers had been reduced to 30 killed and 320 injured. It took another generation with its open road and three-day holidays to send our young people wholesale to Heaven or Hell.

The general public in the United States could not, if it would, remain completely unconscious of the bitter fighting in Europe. While there were 1,216,000 immigrants in 1914, their number had dropped to 307,000 by 1915, and was to drop further. Cheap labor was becoming expensive. Canada was offering free 160-acre farms to U. S. immigrants, "our brothers from south of the border."

As neutrals, we were becoming rich, supplying arms to whomsoever could buy them—and get them. We were at peace, and fervently isolationist. We were proud of being imperialistic, of having a great fleet patrolling both the Atlantic and the Pacific. We accepted Kipling's elevated concept of the White Man's burden in regulating our few precious colonies. Prohibition and the Female Vote were topics of much running jest. But national defense was hardly mentioned in public discussion or current literature.

What were Americans thinking about in late 1915? How to get rich oneself, and yet soak the rich. How to keep labor under control and yet bust the trusts. The "malefactors of great wealth," to quote Teddy R., were yet the envy of every business man. The whole family trees of the 17 American multi-millionaires were treated better than royalty in the World Almanac for 1916. American men and women in 1915, laughing worriedly at Charles Dana Gibson's series of pictures in the old LIFE entitled "The Education of Mr. Pipp," were looking for tricks to get fat. One dieted to round out the figure. It was estimated that 70% of American homes had no bathrooms. A railroad engineer, for an 8-hour day and 6-day week, seemed happy to get $30 a week. The proudly independent American citizen was shocked by the adoption in 1914 of a constitutional amendment permitting a general income tax, especially since in that year vested interests had secured the protection of a Federal Reserve Banking System. Such American men as had, in the interest of culture, deserted the defense (and the offense) of the spittoon, and had descended to the Parisian fad for cigarettes, largely rolled their own.

Life in these United States was indeed at least superficially quite different, as 1916 opened, from what we know it today. The automobile was just coming into its own, and that with a rush. In 1915 the automobile manufacturing companies had produced on the average, twice what they did the year before. The output averaged 325 cars apiece for the year. Of course one could not expect to drive to California by car to see the Fair, even in a fine $400 roadster. The Lincoln Highway, like the Lincoln Memorial, was not yet completed. Less than a ninth of the highways of the country were surfaced. Electric starters, like electric headlights, were luxury extras available on some cars. Sound amplification could be by stethoscope, tin earhorn, or megaphone only. Household family radios were, of course, unknown. It was the heyday of vaudeville. Nickelodeons (an hour's flicks for a nickel) and jitneys at a nickel a trip kept people happily marveling. Neon signs were undreamed of. The World Almanac for 1916 mentioned 37 stars of the silent screen to 340 on the stage. But the "Birth of A Nation," with some dubbed-in color was promising new heights in entertainment, and was rehabilitating the public image of the K.K.K. Kerosene oil was the main source of household illumination, and coal was the main source of household heating. Gasoline was still largely a waste product in the effort to keep kerosene less explosive. A third of our people still lived on the farm. Even as today, so then, New York City was our chief port and our amusement center. It had 56 hotels and could be reached by 36 ferry lines. It was supplied with

almost one telephone for every ten of its inhabitants. In 1916 the World Almanac listed among known scientific facts: speed of light 184,320 mi/sec.; speed of electricity, 288,000 mi/sec. Americans were the world champions of free public education. Out of a national population of 106 million, about one per cent were enrolled in the public high schools, with few taking mathematics. The word "dropout" had not come into use. Of course college was expensive. Harvard even charged $200 for annual tuition. Family life was relatively stable. Only 3 tenths of one per cent of the men and 4 tenths of one per cent of the women had been divorced (you might figure that out!). National Baby Week had been instituted, but only later did they remember to think of Mother's Day. As for mathematics, at the close of 1915 it was undergoing a steady decline in popular prestige. The tradition of mental discipline seemed neither convincing nor attractive to young America. Prophets foresaw mathematics sharing with Latin and Greek, complete extermination from the public high school curriculum. But Pi Mu Epsilon had been founded in 1914.

4. Early Journals. Scientific societies and scientific periodicals have often been associated but not usually. And this general observation applies also specifically in the area of mathematics. However, the story of the Mathematical Association of America cannot be divorced from that of the earlier established MONTHLY.

Precisely, in this general connection, the following statistics arduously gathered at the Brown University Physical Science Library may be of some interest. There are there available 829 separate periodicals devoted entirely to pure mathematics, as well as many scientific journals with some mathematical contributions. Of these 829 journals, 368 seem unquestionably to have ceased arriving, probably due in most cases to cessation of publication, although perhaps in some cases to lapse in subscription or exchange arrangements. Of the 461 nominally still arriving, 72 are issued in the United States or Canada. Of the total continuing 461, only 73 were founded prior to 1916. Of the 72 issued in America and still continuing, only 7 antedate 1916, including *The American Journal of Mathematics* (1878), *Transactions of the American Mathematical Society* (1900), *Annals of Mathematics* (1899), and *The Mathematics Teacher* (1908).

Some years ago was founded in this country *The Mathematical Monthly*. It filled a widely felt want. As promised by its founder, it carried among other regular features, expository articles on advanced topics of mathematics and news of mathematical activities throughout the world. Of special concern to the founder and editor, it maintained a lively department devoted to Problems and Solutions at the collegiate level. An avowed objective was to raise the general level of mathematical education. It was published simultaneously at Cambridge, Massachusetts, and London, England. Although what seemed to some at the time as a high subscription rate of $3 per annum, it continued to increase in number of subscribers and number and quality of published articles. Never did

financial stringency force it to reduce an issue to emaciated thinness. This bold venture started without official sponsorship by any organization. Its founder and editor, John D. Runkle, A.M., was not in the educational field, nor was he, in his words, a professed mathematician. He was a full time government employee engaged largely in routine computing for the Nautical Almanac Office.

The founder pointed out: "All mathematicians know that there are many subjects in the higher departments of the science upon which little if anything has as yet been written among us." Again, "To the student or young mathematician, problems are indispensable to make him *sure*, and to *ground* him in the theory, as well as to exercise and develop his skill." Again, "Care should be taken not to graduate the magazine as a whole too high above the average attainments of mathematical students."

On p. 40, vol. 1, an author remarks on "the already numerous instances so frequently happening in our country of an almost useless expenditure in time and effort at the rediscovery of things brought to light centuries ago."

Although the founding of this periodical was endorsed unanimously by the Section of Mathematics and Physics at a meeting of the American Association for the Advancement of Science, it started with subscribers numbering only 62.

In accordance with the spirit of the time, Runkle established at the start two sorts of prizes: those for undergraduate problem solvers, and some more munificent for authors of expository articles.

Perhaps you will be surprised to learn the names of some of the distinguished regular contributors who helped maintain the high scientific quality of the young magazine. These included Simon Newcomb, Benjamin Peirce, Joseph Henry (of the Smithsonian Institute), William Chauvenet, George Washington Hill, and Arthur Cayley. As for the phrase "some years ago," in logic, "some" means "at least one" or "not none." A historian cringes at the phrase "many years ago," and one need not explain why this account did not start with "Once upon a time." The date was 1858. But what neither apathy nor financial crisis could do, war did. As has happened so often throughout world history to so many periodicals, in the midst of editorial work for coming issues, suddenly without prior notice to anyone, the *Mathematical Monthly* ceased forever to be. The year was 1861.

The resulting gap in mathematical periodicals lasted through the great depression following our Civil War. It was not until 1874 that America recovered enough to support *The Annalist*, which has continued, with a change of name to *The Annals of Mathematics*, through many vicissitudes to this day.

One might mention another periodical founded in 1889 in Manchester, New Hampshire, with the title ending, "et cetera"; namely, *The Monthly Journal of History, Folklore, Art, Science, Literature, Masonry, Mysticism, Mathematics, Metaphysics, Theosophy, etc.* I believe it too has passed away.

5. The *Monthly*. In 1894 was launched another American venture with almost precisely the same objectives and analogous departments as its predeces-

sor, and named *The American Mathematical Monthly: A Journal for Teachers of Mathematics in the Collegiate and Advanced Secondary Fields.* It was founded, edited and published by Benjamin F. Finkel of Drury College, Kidder, Missouri, with the assistance of a succession of associate editors.

One must confess that this new magazine, destined to become the official organ of our Association, springing into being in the heart of the Mississippi Valley, despite its high and wide aims, seems, in retrospect, on the whole, to have started off as quite provincial in comparison with its short-lived predecessor of briefer name. Let me cite some items among many instances. In a eulogy of Prof. E. B. Seitz, Prof. Finkel wrote, "He was the most distinguished mathematician of his day (1846–1883), the equal of the best, the peer of all the rest. Prof. Seitz was in Mathematics what Demosthenes was in oratory, Shakespeare in poetry, Napoleon in war." Equally laudatory eulogies, mainly of living mathematicians, appeared one each issue. Prof. Daniel Kirkwood of Indiana State University was hailed as the Kepler of America. Nor was a chance at a little moralizing to be overlooked. We are told in his biography of Prof. Hoover: "There is a valuable lesson to be learned. It is this: Energy and perseverance will bring a sure reward to earnest effort." Early issues brought much bitter argument and personal denunciation over what most of us would regard as matters of pedagogical taste. However, there was also much to respect. L. E. Dickson, while yet a graduate fellow at the University of Texas, was already launching a brilliant and prolific scientific career, as was David Eugene Smith, then of Michigan State Normal School. G. A. Miller, not yet a millionaire, also contributed regularly. Halsted dealt with charm and excitement on mathematical subjects, without intruding here his popular addresses on such topics as "Dreams," "Suicides," "The Elixir of Life," and "Mexico." E. H. Moore contributed a wise comment.

Among the current publications reviewed in early issues were Fiske's *A History of the United States for Schools*, and an issue of the *Cosmopolitan* for 1894 with a story by Kipling. In response to an inquiry originating from Brown University, the editor stated: "The Trisection of a straight line taken as the chord of a circle trisects the angle of the arc."

The largely rustic quality of early issues of the MONTHLY seems the more surprising in view of the consciousness of mathematical scholarship being developed through the recently founded University of Chicago (with E. H. Moore and his associates from Germany), already in full swing. Even in Texas, George Bruce Halsted had been spreading with singular effectiveness knowledge and enthusiasm in such lines as four-dimensional geometry and non-Euclidean geometry. But perhaps no one of these individually had the world-wide effect that did the mathematical lectures and personality in this country in 1894 of the great Felix Klein, then at the height of his powers and fame. Six years earlier had been founded the New York Mathematical Society, supported by all the leading mathematicians in this country (those in the University of Chicago, among others). In 1894, E. H. Moore secured the publication by the New York

Society in book form of the *Colloquium Lectures* that had been delivered at the International Mathematics Congress held in Chicago in 1893 in connection with the stunningly beautiful Columbian Exposition. In the summer of 1894, in connection with a summer meeting of Section A of the American Association for the Advancement of Science, the New York Society, recognizing its already achieved national status, adopted its present name, the American Mathematical Society.

It is inconceivable that this nationwide contagious interest and deep concern in mathematics did not have a share in starting the new journal at Drury College. But there seems nothing on the surface to show for it in the pages of early issues of the *American Mathematical Monthly.*

Already in 1888, close by in Chicago, mathematicians and teachers of mathematics were meeting regularly in what was to develop through the wisdom and tact of E. H. Moore into the Chicago Section of the A.M.S. Also in 1894, in California, a San Francisco Section had come into being.

The time was ripe for mathematical journals in the English language. In 1894 simultaneously with *The American Mathematical Monthly*, was founded the already mentioned British *Mathematical Gazette.* In 1895, Artemas Martin in Washington was editing and publishing both *The Mathematical Visitor* and *The Mathematics Magazine.*

In the next eighteen years, the *American Mathematical Monthly* endured many vicissitudes, acquiring and changing editors and sponsors, but always with B. F. Finkel at the helm. Even with L. E. Dickson as the associate editor from June 1905 to July 1906, and under sponsorship of both Drury College and the University of Chicago, and later from August 1906 to December 1908 sponsored by the University of Chicago, the issues became thinner as the quality of scholarship improved. The issue for March 1909 had only 16 pages. This was under the joint editorship of Finkel, Slaught and G. A. Miller, and with both the University of Chicago and the University of Illinois as sponsors. With June 1913, there was a general reorganization, with as sponsors the Universities of Chicago, Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, and Nebraska, and with Colorado College and Oberlin College. H. E. Slaught became managing editor, and financial prospects began to brighten significantly. One cannot but note the geographical concentration of the sponsoring institutions.

Before turning to more serious history, you might consider the persistent interest in problems and their solutions at the collegiate level. This department in later years was largely directed by Otto Dunkel. Were a centennial American collection to be made of such problems, a first problem might be the choice of a title, since "Puzzle Parade," "Tomorrow's Math: Unsolved Problems for the Amateur," "Denkspiele für Kluge Köpfe" and "Pillow Problems" have already been preempted, not to mention "Recreationum Mathematicarum" (1659) and the still older "Il Nobilissimo et Antiquissimo Giuoco Rythmomachia" (1572). One might go back to Archimedes and earlier, Pythagoras. Were the title "Wrinkle" still available, what could be more descriptive of the puzzler's brow?

One might well issue as a centennial volume: "*The Wrinkle*" by Runkle, and Finkel, and Dunkel.

6. The Growth of the Association. Although the original constitution has been slightly amended, as in September, 1920, such was the wisdom and foresight of the founders that there has been no major change in plan or policy of our governing body. The four most obvious changes, apart from general growth in volume, complexity and diversity of business, are probably the following:

1. From the start as a matter of precedent desired by each of our first two presidents, Earle R. Hedrick and Florian Cajori, and followed by tacit tradition thereafter, no president has accepted nomination for a second term. Until the year 1925, the term of presidency was for twelve months; but in that year the constitution was amended to provide for a two-year presidential term while also making constitutional the single-term provision.

2. To make it legally possible for the Association to receive gifts (of which many were then and later forthcoming), the Association was incorporated in September 1920. The Council, which had functioned successfully, changed its name to the (19-member) Board of Trustees. Of these 19, seven were members *ex officio* namely the four executive officers of the Association, and the three managing editors of the MONTHLY. The remaining 12 served in groups of four, elected for three-year terms.

3. In 1941, the Board was to be replaced by the more effectively representational Board of Governors, consisting of the officers, the three latest ex-presidents, six governors-at-large and 14 regional governors, these last elected by the representative regional electorates for two- or three-year terms.

4. As a gracious and most fitting gesture, Herbert E. Slaught, fourth president of this Association was elected unanimously in 1913 as Honorary President For Life. After his decease in 1937, a similar honor was voted in 1943 to William D. Cairns, the first secretary and 19th president of the Association.

The growth and maturing of the Association may be suggested by the following items: In January 1916, there were five sections: Kansas, Ohio, Missouri, Iowa, and Indiana. In January 1944, there were 24. In 1916, there were 1045 members. In 1944, the membership amounted to 2270. In 1944 the MAA had representatives on the governing boards of the following: The National Research Council, The American Association for the Advancement of Science and the American Documentation Institute.

While even in 1941, Thornton C. Fry had described the rather limited demand, present or forseeable, for mathematicians in fields other than teaching (he put 15 mathematicians in industry as realistic for that date), and William Betz had for decades mourned and thundered against the vanishing call for mathematics in American education, the advent of World War II had changed the picture, and instantly. In 1942, the Joint War Policy Commission announced that there were about 3000 men functioning as teachers of mathematics in 4-year colleges, but that 2500 would be needed full time for teaching Army and

Navy programs alone. By 1943 there was an acute nationwide shortage of mathematicians—and of paper—and 5000 members of our armed forces were taking correspondence courses in mathematics.

The first of the distinguished succession of the Carus Monographs was that of G. A. Bliss in 1921 on Calculus of Variations. The Chauvenet Prize for "expository articles in mathematical journals" was established in 1926. Its seven recipients in the period through 1943 were G. A. Bliss, T. H. Hildebrand, G. H. Hardy, Dunham Jackson, G. T. Whyburn, Saunders MacLane and R. H. Cameron. A plan for the *Herbert Ellsworth Slaught Memorial Papers* "pamphlets of an expository value, and of from 40 to 80 pages in length," was announced in February 1941, and was promptly put into effect.

A department of Undergraduate Mathematics Clubs was inaugurated in 1919 and was for years directed by R. C. Archibald with unflagging enthusiasm. It may be worth noting that privately Archibald seriously objected to what seemed to him as bureaucracy in the very concept of the Pi Mu Epsilon. He favored strong local faculty control of all undergraduate organizations, unimpaired by national officers.

The highly successful William Lowell Putnam Prize Competition was instituted in 1938.

Now for a rueful thought, here is the advice given by E. T. Bell to the American Mathematical Society at its semi-centennial. Would that it had been heeded here. "Choose young men, preferably under thirty, to review the progress of American mathematics. For if there is anything that will give a man, young or old, a decent humility and a sane humor regarding his own efforts, it is an acquaintance with the work of his predecessors and contemporaries. The earlier this acquaintance is gained, the better for all concerned, including mathematics."

If from this historical retrospect one is to gather any constructive ideas for future development perhaps this one suggestion is worth passing along:

To have a standing provision for two recurrent decennial committees, which each ten years, reconstituted with entirely new membership, would, like the National Census Bureau, asking the same sort of questions, report fresh answers, namely:

1. A small committee on Recommended Books for College Libraries. Its timely up-to-date reports would be read and acted on.

2. A large joint commission with the National Council of Teachers of Mathematics on the Substance and Objectives of High School and First Year College Mathematics. Its reports might not be acted upon, but the Commission members would learn an awful lot.

So to take leave of you,—historically, as of during those somber days and nights of World War II when young and old sang wistfully, "When the lights go on again all over the world." A hundred million lights were about to go on in the electronic computers, blinking a new era in the continuing story of mathematics.

HISTORY OF THE MAA SINCE WORLD WAR II

R. A. ROSENBAUM, Wesleyan University

1. Preamble. Perhaps I may be permitted a personal remark which explains why I am so pleased to be given an opportunity to participate in this celebration: my father, a charter member of the Association, received his Ph.D. here at Cornell. I early came to know the mathematical names in Ithaca: Carver, Gillespie, Ranum, Silverman, Snyder, . . . and Hurwitz, who directed my father's thesis. It is a widely held opinion that mathematicians are especially attracted by two activities —music making and punning. It was Hurwitz, I have been told, who nicknamed a colleague with a reputation for making off with the magazines from the common room of Willard Straight: Procrastination, he called him, the thief of Time.

The summer meeting just 20 years ago was cancelled because of the war, and the first big post-war meeting was here at Cornell in August of 1946, with 277 MAA members in attendance. It's interesting to note some of the names: W. D. Cairns of Oberlin; Newsom, also of Oberlin; Allendoerfer of Haverford (before Winger persuaded him to defect to the West); Carver, Hurwitz, Agnew, and Walker of Cornell; Feller, Jones, Kac, LeVeque, and Rosser, also of Cornell. It looks as though fewer than half of us stay put. But there were (and are) stalwarts, like Gehman, of Buffalo; McShane, of Virginia; Meder, of Rutgers; Tucker, of Princeton.

The war was still with us in various ways: The Reverend J. T. O'Callahan of the College of the Holy Cross was awarded the Medal of Honor; the mathematics departments of several overseas colleges for servicemen were staffed by MAA members; the NRC offered fellowships to promising young people whose work had been interrupted by the war; the problems of rebuilding faculties, of allocating manpower, were pressing, especially in the face of droves of veterans returning to college under the G.I. bill.

We were on the threshold of a new era, involving dramatic changes for the rôle of mathematics in our culture and of mathematicians in our society, and the MAA was bound to be deeply affected. I shall not attempt to chronicle the details of these changes, but rather to sort out some of the dominant features of the period.

My notions of historiography have been influenced by Carlyle's "On Heroes and Hero-Worship," and I shall continue with reference to personalities. Mathematics, after all, is made by mathematicians; and our Association bears the imprint of their interests and enthusiasms, their devotion and hard work, their prudence and logic, their emotions and prejudices. I can select only some examples and will of necessity omit acknowledgement of the equally important contributions of many others.

One of our heroes is the embodiment of our virtues, although he might not appear heroic in other subcultures. I refer to Paul Erdös, whose contributions

to the MONTHLY and to Association meetings we appreciate along with his brilliant achievements in research. Erdös combines creativity and honesty with generosity and humility, extraordinary mathematical talent with exceptional human feeling. With unusual breadth in mathematics, he is able, and ready, to help anyone with a question. He can always find something good to say about the mathematics of a fellow human being, even though he may despise his politics.

It seems a long time since Erdös appeared at the Swarthmore meeting after Christmas of 1946, newly returned from the clothing store to which a group of friends had dragged him, attired in a brand new suit which somehow already looked slept in. There he stood, smiling gently at his friends' silly concern—he didn't resent the time which might have been wasted in buying the suit, for, in truth, no time had been wasted—he had thought about a mathematical problem throughout the merchandising transaction.

How different are our meetings these days! Wandering into our Association meeting at the Denver Hilton, one might think it a convention of successful account executives. "These days mathematicians can *eat*," said a personnel officer of United Aircraft, and how well-fed we are! And well-groomed too.

But it's far from accurate to imply that our ideals have changed. Our Association still harbors innocents who wouldn't notice the sneer when asked, "Have *you* ever *met a payroll*?" and who would respond, "No, I don't believe so; that's an unusual name." We also have a considerable number who have helped very substantially, one way or another, to meet some impressive payrolls. The MAA may be unique among professional organizations in having an unusually *diverse* membership *unified* by some common interests.

Indeed, I think that *unity in diversity* best characterizes our Association during the past 20 years. Let me explain what I mean. There are a number of traditional dichotomies which have become stock phrases:

(1) teaching vs. research
(2) pure vs. applied
(3) classical vs. modern
(4) intuition vs. rigor
(5) science vs. humanities
(6) elementary vs. advanced.

Like most dichotomies, these are invalid oversimplifications. (Indeed, I think all dichotomies are pernicious—except that into male and female.) Just as my caricature of our members as being either absent-minded eccentrics or sleek Madison Avenue operators is fanciful, so likewise are the various polarizations which I have just recited. In each of the relevant categories we see an entire *spectrum*.

In retrospect, it appears that during the past 2 decades the Association has encouraged a dialectic, so that we are beginning to understand and appreciate each other's positions. It is not too much to hope that we will have some reconciliations of diverse positions which will significantly enrich collegiate mathematics.

I should like to describe what I see as the Association's rôle in these dichotomies.

2. Teaching vs. Research. The rubric "teaching vs. research" is too brief to be clear; the debate that I'm thinking of is "(teaching *and* research) *vs.* (teaching *or* research)." The supporters of the first view have been eloquent: it is a perversion of our subject, they say, to separate teaching from research; our students must be exposed to scholars excited about their own creative work, for otherwise those students are likely to think of mathematics as a completed subject; on the other hand, the research worker often finds that in seeking a presentation which is really effective pedagogically, even (or perhaps, especially?) at an elementary level, he is led to a point of view from which his own research is illuminated.

All well and good, say the opponents, if you can find enough such individuals. Unfortunately, Emil Artin is rare (if not, indeed, unique!). Often creative mathematicians are simply not good expositors; and moreover, those endowed with both gifts are unlikely to have the interest, energy, and time to develop both. We are better off if we exploit to the full the talents of master teachers—individuals who are conversant with a broad range of mathematics and with current developments, even if they do not themselves contribute to research in the usual sense. Such a person should hold the position of Chairman of Undergraduate Mathematics at a university, sharing responsibility with his research-oriented colleagues for the shaping of the curriculum, and giving careful supervision to young teachers, for enthusiasm for teaching is as communicable as for research. Further, instead of conscientiously turning out papers, these mathematicians can focus their attention on the work of researchers, analyzing, synthesizing and evaluating results—and writing enlightening articles for the MONTHLY and the MATHEMATICS MAGAZINE. Indeed, we should encourage the *development* of such useful mathematical citizens by offering an appropriate degree, rather than the Ph.D. where research is all important and teaching is ignored.

Oh, no! let's not lower our standards; let's not debase the doctorate, respond the first group. Classifying college and university mathematicians as *either* teachers *or* researchers would be a most unfortunate divisive move. The teacher who is not also a researcher will not have the inspirational qualities, will not have the visceral understanding of what mathematics is all about, these being necessary for the kind of teaching we want. Note the experience of the MONTHLY, which tries to publish exactly the sort of article we were talking about a few moments ago—the thoughtful review of research which gives the nonexpert reader a grasp of where our subject is going. Editors of the MONTHLY have always complained about the dearth of such articles, but we all remember some notable examples: one rich year contained outstanding pieces by Coolidge, Gödel, Kac, and Polya. (Note our debt to Europe.) Well, these are the teachers *cum* researchers who couldn't have done their *teaching* so effectively without their researchers' understanding.

But look, answer our friends on the other side, you're hitting a cripple with his crutch. If our education tried more consciously to develop the analytic and synthetic powers of our young people, perhaps we would find more nonresearch mathematicians who could produce articles as profound as the ones you cited. In any case, the need for talent *of all sorts* appears to be virtually limitless, and the Association has pointed the way toward our involvement in many activities for which we ourselves were not trained; let us help some of our successors to acquire the necessary training.

And so the debate continues—fruitfully, I believe. Five years ago, E. E. Moise was chairman of the Joint Committee on the Doctor of Arts Degree. The decision was *not* to recommend that such a degree be offered; but the problem is still with us, and our discussions may eventually lead to a doctorate with *increased* breadth and *no* loss in depth. We should be mindful of a recent study which disclosed that a high percentage of the ablest American graduate students are bitterly disappointed with their experience—graduate school has not provided the intellectual excitement which they had anticipated. Fortunately for us, the percentage of disappointed students in mathematics (and science) is low, as compared with the situation in the humanities and the social sciences, but we cannot be smug on that account. We have probably made less progress toward a resolution of the teaching-research dichotomy than of any of the others I've listed, and, correspondingly, the mathematical future of the collegiate institution remains in doubt.

This year, when there will be $5\frac{1}{2}$ million students in college, the problem for many of us is not the luxurious one of providing a top-notch teacher-researcher for each of our undergraduate classes, but the desperate one of finding *any* teacher for the job. Not long ago I met a retired naval officer who planned to spend several summers at institutes to prepare himself to teach high-school mathematics. He dropped into the administration building of a college, hoping to get a temporary job as assistant registrar or something similar, until he was ready to undertake high-school teaching. An hour later he emerged as acting chairman of the math department! The teacher shortage is so acute that it won't be solved by other than radical approaches. We must strike out in imaginative ways, utilizing new media (films, TV, programmed materials, computer based instruction, . . .) to obtain a more efficient use of our manpower. We must go to the heart of the matter and encourage greater initiative and independence on the part of the student, so that he won't be so demanding of faculty time. Both our Committee on the Undergraduate Program and our Committee on Educational Media are attacking both aspects of the problem: the immediate one of getting classes "covered" and the deeper, longer range one of giving students some contact with creative, research mathematicians. The CEM began under the leadership of H. M. MacNeille, who is now directing its Calculus Project, aimed at using various media to raise the level of instruction in calculus. Brewster Gere directs a Programed Learning Project; A. N. Feldzamen is Executive Producer of a Film Project which, as successor of the MAA Com-

mittee on Production of Films, will show some of our greatest contemporaries in action. I'll mention the fourth project later.

Many of us believe that a spark can be struck in a brief encounter between an exciting mathematician and a receptive student, and the Program of Visiting Lecturers is designed to strike such sparks. As R. E. Gaskell, the chairman of our MAA Committee on Visiting Lecturers reports, "While the program is supported financially by the NSF, its work would not be possible without the cooperation of the home institutions of the 75 lecturers on our list, who generously grant them time for this work, or without the cooperation of the lecturers . . . , who were given nominal honoraria for the work involved in preparation, travel, and in the visits themselves." As a former member of Gaskell's committee, I can join him in testifying to the hard work and effectiveness of our MAA lecturers. The program has been in operation for over a decade and has been widely imitated in the sciences. During the first several years our lecturers took leave from their universities and went on tour. People like G. B. Price learned of the concert artist's problems with transportation schedules and laundry—with no impresario to smooth the way. More recently the NSF has been willing to support only day-long visits (about 360 of them last year). Our lecturers must make provision for their absence from the campus, and somehow catch up on their return. The NSF and the mathematical community have got their money's worth, and then some, from this program.

There is still a fourth MAA activity aimed at a resolution of the teaching-research dichotomy: the summer institutes and conferences for college teachers. They began in 1953 with an institute directed by B. W. Jones; the lecturers were Artin and Wilder—now there's a pair to try to surpass! This program has given college teachers a chance to get back into the stream of current mathematical work. Under E. A. Cameron's direction, a "multiplier effect" has been incorporated into Summer Seminars: each participant is given released time to conduct a seminar for colleagues at his home institution during the academic year following the seminar.

Let me close my discussion of this topic by referring to a question on which there is no consensus: Just how rare is mathematical talent? Many observers believe that such talent is indeed rare and that we now come close to discovering all of it. According to them we cannot markedly increase the number of Ph.D.'s in mathematics if we wish to maintain traditional standards—the native ability just isn't there. Others (and R. L. Moore might be in this group) believe that many more people could create mathematics if they had the proper instruction. It's pretty hard to devise a controlled experiment to answer this question.

3. Pure vs. Applied. I turn now to the second item on my list, the relationship between pure and applied mathematics. Despite the attention which the Association has increasingly paid to it in recent years, the relationship is uneasy and unsatisfactory. Many mathematicians would agree with the statement of

G. A. Bliss, which appeared in his autobiographical note in the MONTHLY in 1952: "After some careful consideration I concluded that it was really . . . mathematics which had the greatest attraction for me, and I decided to try for a Ph.D. in that subject rather than in astronomy. I have never regretted the decision, though it seems clear to me that one could find great satisfaction in any domain of applied mathematics."

If this were a general sentiment one might expect that there would be no such thing as a dichotomy between pure and applied mathematics, that we would all use problems of the real world to motivate the development of abstract mathematics, that we would then exhibit the "usefulness" of our mathematical results—in short, that we would weave together the pure with the applied to enjoy the fruits of that symbiotic relationship as did our masters Poincaré, Birkhoff, Weyl, and von Neumann. But the actual situation is very different from this utopian prospect. Note a few examples.

Item. One of the world's leading universities has four professorial chairs, two held by pure mathematicians, and two held by applied mathematicians. The four men are socially a congenial group, but professionally they divide into two pairs—in the obvious way—and mathematical interchange between the pairs is nonexistent. Is this not unfortunately all too common? But it's not universal—A. J. Kempner and C. A. Hutchinson of Colorado furnish a counter-example.

Item. The director of a National Laboratory has recently blasted the trend in undergraduate mathematical education, asserting that, in the hands of "purists," the needs of nonmathematicians are being ignored.

Item. A famous physicist is co-author of a new book to teach calculus quickly to freshmen, because he feels that the usual freshman mathematics course does not provide the material which physical scientists need.

It's not that we in the MAA are ignoring the problem. Our Committee on the Undergraduate Program in Mathematics has four panels, of which one is devoted to the Physical Sciences and Engineering, and another to the Biological, Management, and Social Sciences. As R. J. Walker has made clear, the push to introduce linear algebra very early in the undergraduate curriculum has come from the physicists and engineers, not from the "purists." CUPM publications in the offing include sets of computer-oriented problems and engineering problems, to "enrich" our freshman and sophomore mathematics courses. Seminars, conferences, and institutes (some of them year-long) have been held for social scientists and for faculty in business schools. In considerable measure these involve bringing "our" mathematics to nonmathematicians, but there is a substantial feed-back. Almost 50 years ago the pioneering freshman book of F. L. Griffin introduced numerous examples from the social sciences and the life sciences, but this lead was not widely imitated until recently. Now we find in elementary textbooks not only the topics which Griffin's book contained (such as finite probability, and statistics), but also the new tools of the decision maker—linear programming and game theory. The MAA itself has contributed a publication—*Modern Mathematical Methods and Models.*

At a more advanced level our Association collaborated with the Society by publishing as a Slaught paper in 1954, *Special Topics in Applied Mathematics*, the proceedings of an AMS symposium whose purpose F. J. Weyl described in these terms: " . . . the emphasis was on diversity of topics, on highlighting some exciting developments of the day and doing it in a manner to induce broad understanding among the mathematically literate. What we wanted was a collection of significant examples, not brought as yet too often or accessibly to the attention of . . . mathematicians, which would show just how varied and substantial the contributions of the genuinely secular mathematician (as distinct from the monastic one) can be in the interaction of his modes of thought and analysis with the scientific endeavors in other fields." (While I applaud Dr. Weyl's attempt to replace the adjectives "pure" and "applied" with more appropriate ones, I am not persuaded that "monastic" and "secular" are accurately descriptive, when I observe, on the one hand, an academician in Washington resembling a frenetic lobbyist while chasing financial support for his "pure" project, and, on the other hand, an IBM employee sucking reflectively on the stem of his pipe in his "cell" at Yorktown Heights.) To return to the point: the 1953 Symposium on Special Topics in Applied Mathematics is but one of many examples of our Association's attempts to make us old conservatives see the light. I predict that, for the continued health of our subject, this aspect of our education will have to be intensified.

4. Classical vs. Modern. In turning to those features of collegiate mathematics for which I have chosen the catch phrases classical vs. modern, intuition vs. rigor, science vs. humanities, I remind you of where we stood 20 years ago. In a 1946 review in the MONTHLY of Murnaghan's *Analytic Geometry*, C. C. MacDuffee, the first post-war president of the MAA, quoted with approval a remark of the author of the book, "The demands of modern physics and engineering for a knowledge of the elements of calculus are so pressing that it is no longer practicable to postpone the teaching of calculus to the sophomore year." How things have changed, and how the pace of change has quickened!* Just before World War II, Arnold Dresden, one of the most respected, and usually one of the most effective, leaders in both Association and Society affairs, persuaded some colleagues in colleges and universities to meet for a discussion of needed reforms in the undergraduate curriculum. The group met, came to general agreement—and there it ended. The urgency which Dresden felt (and doubtless some of the others felt it, too) was not translated into action.

After the war the atmosphere was different. In fairness to ourselves, it should be noted that our concerns did not stem from Sputnik—these concerns

* In 1940 the General Education Board subsidized a study, directed by F. L. Griffin of Reed College, to suggest an integrated mathematics curriculum for a small college. Now, only 25 years later CUPM has done something similar with its General Mathematics Curriculum. How our subject has changed in this period!

had been growing over a period of years, and their time had come. Of course, the Russian space shots accelerated our activities and facilitated our obtaining the funds necessary to implement our ideas. But we would have gone ahead anyhow. Indeed, support for experimentation, both by the MAA as an organization and by MAA members, came initially from private foundations rather than from the government, and the so-called private sector of our economy continues to give us vitally important help. Not only the large foundations, like Carnegie, Ford, Rockefeller, and Sloan, not only the giant corporations like U. S. Steel, IBM, and Bell Telephone, but also the smaller organizations like Research Corporation have made and continue to make grants which encourage us to keep striving for perfection. And we shouldn't forget the number of man-hours of MAA committee time, and the number of man-hours of individual MAA members' time, that have also been devoted to this striving for perfection, *without* any financial support.

The people who started CUPM did their initial work without subsidy. I needn't say much about these developments, because William Duren will speak about them at our fifth session, on Thursday. He can be relied upon to be a faithful historian in all but one respect—he will undoubtedly underplay the significance of his own work in making CUPM the effective arm of the MAA which it is. We are all much in his debt.

Earlier I mentioned one of the MAA publications which grew out of CUPM work. There are three others which are related to the topics I am now discussing:

Elementary Mathematics of Sets, with Applications;
A Freshman Honors Course in Calculus and Analytic Geometry;
Universal Mathematics.

Without too much forcing, I can use these publications as foci for the points I want to mention.

The language of sets, and the theory of sets (whether elementary or advanced), have become synonymous with "modern" mathematics, in some quarters. It is doubtlessly true that the notion of a set now plays an important rôle in collegiate mathematics; and that, whereas the word occurred infrequently in the MONTHLY in 1945, it is now sprinkled liberally through that journal's pages. Perhaps more startling is the situation with topology: mention of the subject in the MONTHLY was rare in 1945; articles and problems involving topology are now common. In the undergraduate curriculum, number theory and geometries have probably suffered as work in topology is introduced, either in courses on topology per se, or as adjuncts of courses in analysis. The MONTHLY and the MATHEMATICS MAGAZINE may offend some mathematicians by still devoting "too much" space to classical number theory and geometries, but the journals may serve an important balancing function through their conservatisms in this regard. Indeed, our Association seems to push the pendulum into a daring swing when it shows signs of slowing onto dead center, and to pull the pendulum back toward stability when the amplitude gets too large.

The Freshman Honors Course in Calculus and Analytic Geometry is an outline of what Emil Artin offered at Princeton. No course has received more attention than introductory calculus, perhaps in part because of the profit to be made from a successful textbook. Some texts seem to do no more than warm over cold and mediocre mathematics, but there have been many in the past 20 years which contain features of mathematical and pedagogical distinction. One of our dichotomies constitutes a source of apparently endless debate: intuition vs. rigor. We get agreement on the dictum, "The student should not be taught anything that he will have to unlearn later," but here agreement stops. In all likelihood we cannot expect a single approach to be successful with all students, and the constant debate may be useful as a reminder of this fact. Over the years the MONTHLY has published some helpful and provocative general articles on the subject (one by Walter Prenowitz is especially noteworthy for its sensible, judicious tone), and also some papers on specific topics, like A. E. Taylor's on L'Hôpital's rule and E. J. McShane's on Moore-Smith limits, which have made direct contributions to improved textbooks and classroom presentations.

Mathematics may be universal in a nonpersonal sense, but whether it can appeal to all people and be understood by all people is another question. Nevertheless, most of us think that we have to try. Fortunately, some of us have been reasonably successful—our hard-working Secretary, Henry Alder, reported not long ago on a course for nonscience majors. J. Robert Oppenheimer is pessimistic about what can be accomplished in physics—he fears that the concepts are so difficult that life-long study of physics is necessary for real understanding. Very likely he is right, in terms of the kind of understanding which is his ideal, but I'm willing to settle for a much more modest goal—I just want the man in the street to know that balancing my checkbook isn't part of my professional life. So I applaud Henry Alder and the others who are trying to bring mathematics to nonscience undergraduates. *From the point of view of our society there is no more important teaching that we do.*

5. Elementary vs. Advanced. I come now to my last dichotomy—elementary vs. advanced. It's appropriate to consider it last because it can give us a good feeling—we have taken remarkable steps toward a resolution since World War II. Collegiate mathematics stands in the middle, reaching out in one direction to graduate mathematics, the educational goal of some of our majors and the source of our faculty members, and reaching out in the other direction to pre-college mathematics, the professional goal of some of our majors and the source of our students. For many years we reached out much more eagerly in the direction of graduate mathematics than in the direction of pre-college mathematics. The advanced mathematics provided rewards of all sorts, from fun to recognition. The elementary mathematics was boring, grubby, frustrating, dominated by nincompoops, and riddled with politics. Besides, we didn't know anything about it. But we've learned! The willingness of Marshall Stone to under-

take work in mathematical education because of his realization of its importance should be a lesson to us—and it has been. Think of our distinguished Association colleagues who have accepted chairs in mathematics *and education*. Think of our many Association colleagues who have worked on projects from the College Board Advanced Placement Program down to the first grade. Think of the MAA High School Contest, with over 250,000 participants this past year. Think of the Association Program of Secondary School Lectures, which reached over 600 schools this past year; after almost 10 years of Association sponsorship, the high school program in mathematics (like those in the sciences) will be operated by state-level organizations, but our MAA Committee is continuing its concern for useful service. Think of the concern for teacher training, as exemplified by the thoughtful and detailed suggestions of a CUPM panel which began under John Kemeny's leadership and has prospered under the direction of E. E. Moise and G. S. Young, Jr.; these suggestions have been taken up by a CEM project initiated by Bernard Jacobson and now headed by C. B. Allendoerfer; we can expect that useful materials will soon become available.

The number of our members who are involved in this kind of work, their commitment, their willingness to accept criticism from experienced school teachers—all point to a growth toward unity over a spectrum of levels of mathematics which is the most hopeful sign for the future that I can imagine.

6. Other Activities and Problems. What have I left out? Numerous things:

(a) Size. We have over 16,000 members now. By only slight juggling of data we can say that our growth is explosive, i.e., exponential. If we maintain the same rate of growth in the future (and we all know that it would be unworthy of an American organization to settle for a *reduced* rate), then at our sesquicentennial, 100 years hence, the MAA will have 200 million members. In connection with this extrapolation, I am reminded of a story emphasizing rough approximation. An attractive young woman, attired in a striking strapless gown, with a canary perched on her shoulder, entered a bar, drank three martinis, looked over the group of handsome men on nearby bar-stools, and announced, "I'll go out with any man who can guess the weight of this canary." The handsomest man in the place quickly took up the challenge; he stepped forward, made his appraisal, and said, "Forty pounds." The young woman looked at him admiringly, smiled sweetly, and replied, "That's close enough."

As impressive as the size of the MAA is the size of individual departments. Where, 20 years ago, the News and Notices used to report that a certain institution had appointed Dr. X as instructor, we now have universities appointing platoons and regiments of mathematicians, mostly at officer rank—no privates. When we have 200 million members, I suspect that half of them will be in California and the other half in New York. Assuming that we remain as peripatetic as we are now (through leaves, sabbaticals, grants, contracts, and projects), mathematicians on the East and West Coasts will switch positions year by year.

The two MAA Journals—the MONTHLY and the MATHEMATICS MAGAZINE—are growing in size, too. One of the attractive features of these magazines has been their small size—one can hold the journals comfortably and browse through their various departments, almost like the *Saturday Review*. But now so many books are being published that the magazines threaten to get fat just to give adequate notice of new publications. The backlog of articles is comforting to the editors and distressing to the authors. How will we cope with this problem? That's a worry for our Committee on Publications.

(b) Various awards and prizes, including the Award for Distinguished Service, the Chauvenet prize, the L. R. Ford Awards, and the Putnam prize competition (with 1500 undergraduates participating this year).

(c) Various hard-working committees, such as the committee on advisement and personnel, and the finance committee.

(d) Various publications, like the Carus monographs [I mentioned the Slaught papers earlier].

(e) Hedrick Lectures.

In many ways the MAA has grown into a worldly organization. (Can you imagine—we have bellhops to carry our bags to our rooms!) We nonchalantly accept millions of dollars from the NSF to support our major projects. But we're not really in the big leagues, thank goodness—we don't build linear accelerators. Al Feldzamen makes movies for our CEM at a fraction of the cost of those of other scientific organizations. Harry Gehman makes every nickel count and maintains an avuncular relationship to 16,000 nephews and nieces—a sort of Dutch avuncular relationship. Amazingly, we have preserved some of the *personal* qualities of the MAA which characterized its early days. As I said at the start of this talk, I mentioned a few names by way of a *sample* of MAA activity: we enjoy the participation of a tremendous number of our members in our affairs—on the Board of Governors, on Committees, in our Sections, and so forth. This is an impressive source of strength, and I hope that we can continue the tradition. For, mathematics, after all, is made by mathematicians.

CUPM, THE HISTORY OF AN IDEA

W. L. DUREN, JR., Chairman, CUPM, University of Virginia

I. Fifty Years of Undergraduate Mathematics Teaching.

1. *The idea.* It is appropriate for us in this fifty-year anniversary celebration of the Mathematical Association of America, the national organization of American collegiate mathematics, to review the state of undergraduate mathematical education in the past fifty years, look as best we can towards the future, and consider the work of the Association in it. We shall not be concerned only with the history of a certain standing committee, called CUPM, the Committee on the Undergraduate Program in Mathematics, but more generally with the idea of organizing nationally for the improvement of undergraduate mathematics as it occurs in the classroom and in the college.

2. *Before 1915.* Therefore let us begin by sketching very briefly the significant events and forces in American college mathematics in the fifty-year history of the Association. When the MAA was formed in 1915 there was another movement taking shape which was to have far more influence on college mathematics than MAA would have. This was the extension of compulsory general education in the United States from 8 years to 12 years, that is, to age 18 or through high school. Prior to World War I the American high school had been largely academic and college preparatory. Though public and tuition-free, it had a somewhat restricted enrollment. Mathematics was accepted as a standard subject. The student was expected to complete one and a half Carnegie units of high school algebra and one unit of plane geometry as a minimum college entrance requirement, set by tradition. This same mathematics package was also widely adopted as a high school graduation requirement. The mathematics teacher in the high school usually had completed the equivalent of a minimal undergraduate major in mathematics and many held the master's degree from one of the new American graduate schools formed after about 1890.

These new American graduate schools were beginning to produce an oversupply of graduates with the Ph.D. and their graduates had to take positions in undergraduate teaching for which their graduate education involving research capability went beyond anything they needed or could use in their teaching, and tended to make them discontent with their lot. The leading mathematicians in the American Mathematical Society were bent upon the establishment of a true research community in the universities. Undergraduate mathematics was a burden to them, even if it was a source of financial support as a job outlet for their graduates. However, it was to their credit that these mathematicians, in their drive towards research and graduate work, paused long enough to provide for undergraduate mathematics by helping to establish the Association. Indeed all American mathematicians can justifiably take pride in their continued concern for the teaching of our subject in schools and colleges [23].

3. *Twenty-five year depression* (1915–1940). The extension of compulsory general education through high school age soon overwhelmed the high schools. School educators rejected college preparation as the meaning of high school in favor of a long series of "needs" and "life adjustment," student-centered, philosophies which relegated the difficult subject of mathematics to a low priority indeed. Vocational education proliferated. The level of mathematics required for graduation was greatly reduced and the qualifications of mathematics teachers were ignored. In the colleges this hurt mathematics more than any other subject because it is far more dependent upon years of previous school preparation than the others. High school graduates, going to college in greater numbers over low admission requirements which reflected the colleges' need of their tuition money, soon reduced the subjects of college algebra and analytic geometry to remedial high school, and even grade school, mathematics under various euphemistic designations. The job of the well-trained mathematician teaching in an undergraduate college became still more unattractive. Several commissions of national scope, attempting to remedy the situation, failed [24]. This state of affairs continued until after World War II. Indeed, despite a reversal in the more visible sectors of the educational system, it continues today as the dominant environment in very large sectors which are less favored.

It was my privilege to come into the Association about ten years after its founding and in that stage of life when a brash young man says in effect: "Now that I am finally here, will the world kindly step forward and justify its existence." In my limited world I expected MAA to justify its existence. Was it a professional organization, or union, looking after the economic and social well-being of its members? No. Was it an authority maintaining professional or educational standards? No. Was it devoted to the teaching of mathematics? No, not directly. No, I finally decided that MAA existed to give comfort and status to college mathematicians. It was organized to hold meetings, elect officers, select hour speakers, and publish a journal, just like AMS, only at not so high a level. That was not bad. College mathematicians certainly needed comfort and status. This role of the MAA continues today, but no longer as its only role.

4. *Revival of public support* (1941–1957). After World War II American industry perceived its need for more mathematical education for its employees and, before the impact of either the computer or Sputnik, began to advertise this and offer jobs to mathematicians at all levels. So did government. The National Science Foundation entered the picture, expressing the national policy to cultivate science for the public welfare by an early emphasis on graduate study and research.

In 1953, before Sputnik and before the computer had run wild, E. J. McShane, as President of the Association, sensed the opportunity for educational reform which the new public support would give and appointed a special committee on the undergraduate program, where "program" meant the entire system: the curriculum, the teacher, and the student. This *ad hoc* committee made

a quick survey, reported back to the Board of Governors at the Kingston meeting in September 1953 that there was a "widespread dissatisfaction" with the college mathematics program and recommended a national "program of 'doing' to overcome the inertia of the enormously ponderous structure which carries onward the present program with all of its deficiencies [13]." Then the *ad hoc* committee asked to be discharged. The MAA Board approved the report and directed that the committee be reconstituted as an official committee of the Association to get on with the "doing."

We will return later to narrate the story of CUPM in its effort to "get on with the doing." Here let us note the significance of this action of the President and Board of Governors of MAA. By forming CUPM as a standing committee they involved the Association in undergraduate teaching in a role which it had never played before. This policy change was reinforced later by the formation of the committees on institutes, visiting lecturers, and more significantly the Committee on Educational Media. CUPM was established early enough to set up some patterns for national curriculum work in mathematics, notably the use of summer writing groups [2] to produce source books for new texts, early enough so that it could help to establish the School Mathematics Study Group for elementary and secondary mathematics, and in turn that was early enough so that SMSG could ride the crest of the big computer and space science wave and take advantage of it to make "the new math" a reality in public education. The formation of CUPM was early enough for it to furnish resources for the NSF Summer Institutes program in mathematics. Spreading to the sciences, this idea of organized national curriculum work in science education has become a very big thing in the United States and the leadership of the mathematicians in these matters is generally acknowledged. The idea is spreading abroad, as other nations [17] begin to move in similar ways. It has definitely taken hold. However, we are getting ahead of our story. We return to the general history of U.S. college mathematics.

5. *The space age begins* (1957–1965). The new demand for mathematics and the new Federal support quickly transformed life (and salaries) for university mathematicians. The effect accelerated as the computer field developed and went into orbit with Sputnik. It was pleasant for college teachers to read about the new importance of mathematics too, but overall, matters only became worse again for college mathematics teaching. By cruel irony, now that better students were here, especially the much desired majors in unprecedented numbers, and now that undergraduate mathematics could really challenge a teacher with a full graduate education, such teachers were not available to the great majority of colleges. The new demand had taken them away at the same time that it presented the colleges with five times as many advanced students as before [20]. This is the state of collegiate mathematics as of this date in 1965. With the biggest opportunity and the biggest task it has ever had, the U. S. college teaching staff is probably at the lowest average level of qualification in the 50 years of

MAA. By contrast, in the favored institutions, where most of the members of MAA curriculum committees are, the conditions of undergraduate mathematics are markedly improved, especially the students and the honors programs for the good ones designed by interested and capable faculty members. The disparity between the haves and have-nots in college mathematics has greatly increased in the last 10 years.

6. *The next 50 years* (1965–2015). Let us now try to look into the future, something which is always dangerous to do and even more dangerous not to do.

The easiest prediction to make at the present time is that the graduates of "the new math" in the schools will be so much better prepared, so much more advanced, and so much more sophisticated that we must prepare to teach first year students subjects which we formerly taught in graduate school, only in a more modern way. The only difficulty is in predicting exactly what fraction of the students entering college in the future will qualify for anything from one semester's advanced placement in calculus to the high level just described. Certainly the absolute numbers of students entering with advanced capability will increase, and surely they will gravitate to more favored institutions, as they do now. There they will not need CUPM help.

However, we can infallibly and inexorably predict that the most significant factor in American college mathematics in the next 50 years of MAA history will be the massive expansion of college enrollment, initiated by national, state, and local policy to extend general education from 12 years to 16 years, that is through college, and made as near compulsory as possible. The colleges will be overwhelmed by numbers and mediocrity just as the high schools were in the past 50 years as a result of the expansion of general education from 8 years to 12. This fact will far outweigh the influence of the advanced placement students in the majority of the colleges. Unhappily the college mathematics teaching staff of 1965 may be nowhere near as well equipped for the expansion as the high school staff of 1915 was. I am sure that American college teachers of mathematics will carry out their part of this grand educational undertaking with pride and to the best of their ability. We may also be sure that national organization to improve college teaching in mathematics, the CUPM idea, will be called upon to do everything possible, especially to enable teachers to teach more students, to teach subjects which they do not know, and enable both teachers and students to learn more by themselves.

7. *The objectives of a national curriculum committee.* It is clear enough what a national curriculum commission should do when, as in some European countries, it has authority to establish a curriculum and impose rigid standards. In the absence of any desire for or prospect of such power it was not clear in 1953 what the American CUPM should do, and it still is not clear. Several possible objectives have emerged and undoubtedly more will come out of experience. In 1953 the college program was not as good as the existing staff was

capable of teaching, or the students of taking, so the first objective we saw was to rally mathematicians to do better teaching, to halt the pessimistic retreat to remedial mathematics, to modernize and upgrade the curriculum, and to enlist the aid of the best mathematicians in this. This called for radical and bold forward steps, for a certain amount of showmanship. This objective will always be present. Yet now in 12 years we appear to have reached a stage where the curriculum has advanced faster than the teacher and the objective must be shifted to give aid to the teacher who needs help. It is no longer helpful to recommend that he teach more modern material, if he cannot do it.

I know that I am now departing from the role of a historian to express personal opinions but I should like here to make a plea as forceful and urgent as I can to university mathematicians, who work in CUPM, CEM, and institutes for college teachers. Find out what their job really is, what these college teachers are capable of doing, and give them something which will help them. Don't assume that it is like your job in your university. It isn't. Have the courage to keep the mathematics you offer them simple and appropriate to their tasks. It will not always be mathematics that you are proud of, not as general, modern, radical, original, innovative as you would like to represent your contribution. But if you want to share mathematical culture as you know it in your university with the teachers and their students in large and small colleges, you must start where they are and give them something they can use.

II. The History of CUPM.

8. *The original ad hoc committee.* We have related above how E. J. McShane as President of MAA in January 1953 appointed a Committee on the Undergraduate Program to consider what could be done about the state of undergraduate mathematics in the United States. The committee consisted of G. B. Price (Kansas), A. L. Putnam (Chicago), A. W. Tucker (Princeton), R. C. Yates (U. S. Military Academy), and W. L. Duren (Tulane), Chairman. The first internal memorandum called for policy decisions: To avoid criticism of public policies on education, concentrate on the technically capable students of the first college year, maintain liaison with engineers and physicists ("our best customers"), cultivate new relationships with the social scientists, consider a radical, abrupt change or nothing, be wary of overdoing abstract mathematics, reenlist the interest in college teaching of the best young and old mathematicians, and work to unify departments of mathematics and oppose splintering them. The ever-present problems of supported textbook writing in the public domain were considered in the same first memorandum.

The final report of the group was made to the Board of Governors in September 1953 [2] finding the "widespread dissatisfaction" and recommending: 1) That a "working committee" of five be established to "direct the work, prepare syllabi and commission the preparation of experimental teaching materials to implement a widespread trial of new mathematics courses in colleges;

2) That a subsidy of some $75,000 be sought . . . ; 3) That the working committee be allowed to make decisions . . . upon a basis of their mathematical knowledge and judgement, rather than ones which require ratification by any other body than the Board of Governors of MAA; 4) That the working committee be charged with studying especially the needs of the social sciences, the new needs of engineering and physical sciences, of modern statistics, and biological sciences; 5) That in the interest of liberal education a single theoretical core for a freshman course be sought instead of a battery of specialized courses for special programs; 6) That the new program be established on its own merits by experimentation without authority, accreditation or other form of compulsion; 7) That commercial relationships incidental to the preparation of text materials [be so managed] that the Association will not be in the textbook business."

The report was approved by the Board of Governors which directed that the recommended continuing committee be formed. The continuing committee appointed was the same as the *ad hoc* committee except that C. V. Newsom replaced R. C. Yates to effect a liaison with a joint committee of MAA and NCTM on teacher training.

9. *The work of the old CUP.* The CUP immediately began planning for a summer writing session which was to be held at Lawrence, Kansas, under the direction of G. B. Price, supported by the University of Kansas and a small grant from the Social Science Research Council via the Committee on the Mathematical Training of Social Scientists. The 1954 Kansas Summer Writing Group produced a volume of experimental text materials called "Universal Mathematics, Functions and Limits" [27], and some preliminary writing on a second volume called "Elementary Mathematics of Sets" later completed by an enlarged writing group at Tulane University and the University of Virginia [12].

These materials were tried out in classroom use at Tulane, Kansas, and University of Alabama among other places. These departments wrote critiques of their experience with it [14] [15].

A grant from the Ford Foundation supported the printing and distribution of these materials and later CUP enterprises. Even so, the early work of CUP was done largely on a volunteer basis without fees and with meager stipends for summer writing. This was one of its major mistakes, not to have a big grant.

The first major report of CUP in 1955 described these and other activities of CUP and related curriculum groups [2]. The report called for a single first year analysis course with a division thereafter into a classical calculus course and a new course in mathematical analysis for the social sciences. The latter was a new course for which the text material did not exist. The Dartmouth Writing Group of 1957–58 under the direction of J. G. Kemeny undertook to prepare a source book for this course, under the aegis of CUP. They were published in two volumes under the title, *Modern Mathematical Methods and Models* [19].

Other books encouraged by small helping grants from CUP but mostly

moral support in this period included Artin's *Notes for a Princeton Honors Course in Calculus* [1], Polya's *Mathematical Discovery*, vol. I. [26], and two or three *Carus Monographs*. In addition CUP supported preliminary writing or exploratory studies but not the final published version for several other books.

The idea that CUP would conduct open discussions in the mathematical community of important current issues in collegiate mathematics proved to be a fruitful one, especially in MAA meetings but also in conferences and in institutes [21]. Some typical questions were: The place of logic in undergraduate mathematics courses—now pretty well talked out—statistics [28], early calculus, undergraduate honors work or "undergraduate research." In this same pattern the later CUPM sponsored, without commitment of its own, the New Haven conference on the Doctor of Arts Degree in Mathematics.

Although there were some additions to the original committee including E. J. McShane, J. G. Kemeny, and Brockway McMillan, there had been no provision such as we have now for regular rotation. The committee thought that no small group should remain so long in such a pivotal position in mathematical education. Moreover, the limitations of its scope and available energy were not adequate to the rapidly developing national curriculum work, even after establishing a Central Office at the University of Virginia with R. L. Davis as full-time Executive Secretary. Accordingly the old CUP resolved to liquidate itself to clear the way for reorganization of CUPM with new blood and larger organization.

I might comment here upon the forms of organization of national commissions for improving education in a particular subject. The more common form, because of red tape and organization politics in national professional organizations, is to set up an independent commission under its own board usually housed in a privately endowed university. The difficulty with this is that it tends to become a self-perpetuating clique, not representative, and with a small number of individuals too long in control. The MAA idea has the advantage of a permanent national professional organization having a charter as the unique organization concerned with college education in its field, which can keep its CUPM continuously changing by limited term appointments, and can offer not only prestige but also publishing facilities, the communication facilities of its meetings, and liaison services not otherwise obtainable. Thus under the MAA-CUPM plan the national curriculum committee should in theory have assured prestige, viability, better national representation, better communication facilities for long-term operation than the independent commission can achieve.

The original CUP summarized its own work in two reports [3] [4], with some suggestions for new directions in CUP work. Almost as an afterthought these reports included a sketchy outline of a recommended college curriculum in mathematics. The old CUP had avoided making recommendations as being too prescriptive, but came to believe that its successor CUPM should publish recommendations, and it did, as we shall see.

10. *Reorganization of CUPM.* Before proceeding to reorganize CUPM the Association held the 1958 Washington Conference to review the overall program of the Association and formulate a plan of action [16]. This conference re-emphasized the change in character of the MAA to incorporate organized national curriculum work by recommending that the Association recognize five semiautonomous "departments" to carry on its old program of publication and its new programs on the undergraduate program, institutes and visiting lecturers, competitions, manpower and professional guidance.

With CUPM thus endorsed as a distinct arm of the Association, MAA in November 1958 conducted a conference, specifically on CUPM [22] which outlined a structure and a program of work for CUPM, including the preparation of a statement of minimal standards for mathematics teachers "in high schools, junior colleges and colleges," and a statement on preparation for graduate work in mathematics. It emphasized the need of textbooks and urged CUPM to develop a program of subsidized textbook writing. Also it recommended that CUPM delegate specific fields of work to "subcommittees" whose members need not be members of CUPM. These were later called "panels." I might comment that the result of enlarging CUPM itself, forming the panels, and other substructures ultimately brought the number of mathematicians holding appointments in CUPM to about 80, compared with the original 5.

The conference did not neglect to advise CUPM to get a grant from the National Science Foundation.

Early in 1959 incoming President Allendoerfer, upon the recommendation of the outgoing President, G. B. Price, appointed the new committee to consist of G. B. Price, Chairman, E. G. Begle, R. C. Buck, W. T. Guy, R. D. James, J. L. Kelley, J. G. Kemeny, E. E. Moise, J. C. Moore, Frederick Mosteller, H. O. Pollak, Patrick Suppes, Henry Van Engen, R. J. Walker, and A. D. Wallace.

The year 1959 and half of 1960 was devoted to organization and efforts to secure funds, which ended in June 1960 with a grant from the National Science Foundation adequate to support the Committee for full scale work for two years.

11. *CUPM operation under a large grant.* In April 1960 R. C. Buck was appointed chairman of CUPM. It became his responsibility to make good the proposed program of expanded activity. Under his leadership CUPM established a new Central Office at Rochester, Michigan, with Robert J. Wisner as Executive Director. It extended its work by establishing four panels: a Panel on Teacher Training with J. G. Kemeny as Chairman, a Panel on Mathematics for Physical Sciences and Engineering with Robert J. Walker as Chairman, a Panel on Mathematics for Biological, Management and Social Sciences with Patrick Suppes as Chairman, and a Panel on Pregraduate Training of Future Mathematicians with J. C. Moore as Chairman. Each panel had several members

of CUPM on it, other non-member mathematicians, and other scientists from the customer fields who were not professional mathematicians.

From this point this history will not record all of the names of the CUPM family, since they are given in the published annual reports of CUPM [5] and assembled in the appendix to this report.

The newly organized CUPM adopted a basic policy in which it felt that it was diverging from the original group. It involves a critical issue in the idea of organizing nationally for the improvement of mathematical education. As expressed by Buck, it began: "Any approach to college curricula revision must take account of valid differences of opinion about both content and pedagogy; thus there is no attempt to insist upon one specific program." The original CUP, SMSG, and CEM tried to carry out this principle by making no recommendations but, for economy of their own efforts, or for unity in presenting what they had to say, or for reasons of belief that in any one school the basic mathematics courses should be unified as much as possible, they tried to exhibit only one sample of source material for each course. All of them have had difficulty in being understood in this.

The new CUPM chose to carry out this permissive policy of allowable variation in a different way. It made curriculum recommendations but, not only was there diversity by virtue of the independence of the four panels which made them, but, as Buck continued: "In all documents released by CUPM, there have been attempts to indicate alternatives, and indeed to encourage experimentation as an aid to national activity." Accordingly, each of the Panels produced at least one curriculum recommendation for a four-year curriculum for students with special interest in its field and most of these offered alternative structures [6] [7] [8] [9].

Kemeny's Teacher Training Panel, working very hard, came up with its recommendations in a matter of months, then initiated a series of conferences, state by state, to review them with administrators, supervisors, and teachers. Unquestionably these CUPM recommendations have been very influential, especially in the training of elementary teachers, hitherto a difficult group to reach.

The success of this conference plan was due in no small measure to the great energy and imagination of R. J. Wisner as Executive Director. Besides organizing the Central Office, Wisner invented the Consultants Bureau and traveled tirelessly to make the Central Office concept a reality as a means of carrying on the work of CUPM in a magnitude not possible with only the voluntary part-time service of committeemen. Other Executive and Associate Directors of CUPM who have ably carried on the Central Office work while on one or two years leave from their universities are: Bernard Jacobson, A. B. Willcox, B. E. Rhoades, and R. H. McDowell (current Executive Director). For the CUPM idea of organizing nationally for the improvement of mathematical education to succeed, it has turned out that an effective Central Office is an absolute necessity.

When we come to the work of the other panels, in fields where the educational objectives are less specific than in teacher training, it becomes more difficult to evaluate the influence of CUPM recommendations. In reviewing the history of the idea of national curriculum organization in mathematics it would be desirable to do so. The nature of the influence is expected to be different from panel to panel.

The Physical Sciences and Engineering Panel, under the chairmanship of Robert J. Walker, has been remarkable for the patterns of consultation and collaboration that it developed with the Engineers, including at an early stage a conference with some 50 leading engineering educators, continuing through its progressive but realistic curriculum recommendations, its significant recommendations on work in computing [7], its source book of engineering problems [25] produced in collaboration with members of the Commission on Engineering Education, and its continuing work on curricula for space science and mathematical engineering. Its service attitude was expressed by C. W. Jones in his inaugural lecture as Professor of Applied Mathematics at Imperial College [18], comparing CUPM's report with that of a similar European committee: "The difference between these two reports is that whereas the American Committee consists of mathematicians who, having gone to some trouble to find out what is needed, are able to state in detail how it should be provided, the OECD report is the work of engineers and scientists . . . who have a lot to say about the drawbacks of the present state of affairs in Europe"

By contrast, the Panel on Biological, Management and Social Sciences, chaired first by Suppes, then Kemeny, and now chaired by Samuel Goldberg, is working in an underdeveloped country. Its recommendations are a kind of chart for the future, saying what is needed. The future work saying how that should be provided will of necessity demand a partitioning of this too-large collection of fields and will require the preparation of source materials, particularly in the least developed segment, biomathematics.

The work of the important Panel on Pregraduate Training has not yet appeared to be viewed as a whole. Its first document on *Pregraduate Preparation of Research Mathematicians* [8] was aimed too far into the future to be immediately useful to any but young mathematicians in the formative stages of their teaching. The panel's forthcoming recommendations on *Preparation for Graduate Study in Mathematics* is a more contemporary document describing how the goals of the first report can be approached in an existing department with available texts.

Much of the work of the Advisory Group on Communications, chaired by A. W. Tucker, is on publications policy of internal interest in CUPM but affecting the development of the idea of national curriculum work. However, working originally as an *ad hoc* Library Committee under the chairmanship of Arnold Ross, it produced a recommended Basic Library List [10] for a small college library. This may turn out to be quite timely and important in the forthcoming

era of Federal support of new institutions to meet the college enrollment expansion in the U. S.

The published reports of the panels by no means represent the total effort of CUPM. From the beginning the members of CUPM contributed to the programs of the Mathematical Association and its Sections and to the deliberations of many other scientific bodies and Federal commissions on problems of mathematical and scientific education. Creighton Buck, Baley Price, John Kemeny, Henry Pollak, E. J. McShane, A. W. Tucker and others have been very active in this speaking service, which has turned out to be one of the most important activities to stem from CUPM. In addition CUPM designed a number of seminars, conferences, and film projects which were carried out by other organizations with separate financial support.

In March 1963 it was decided to move the Central Office to Berkeley, California. In June 1963 W. L. Duren, Jr. assumed the chairmanship of CUPM for a three-year term. R. C. Buck remained on the Committee. There was no change in the policy to take account of the diversity of opinions and objectives by offering alternative solutions in CUPM reports.

A major effort was then directed to construct the forthcoming *General Curriculum in Mathematics for Colleges* (CMC) which is an economical synthesis of the panel recommendations for colleges whose programs are too limited to mount such a diversity of courses as the panels all together recommend [11]. This report introduces a new pattern for such statements. Instead of a curriculum, the CMC report offers a system of one-semester course modular units from which a large number of curricula can be constructed in a single department.

In another new pattern, the CMC report is being offered, not as a CUPM recommendation, but as a report to the Association with request for evaluation and criticism by the Sections. If the Sections take hold of this assignment it could be the means of extending within the Sections that transformation and enlargement of purpose which the idea of organization for curriculum improvement has already produced in the national Association.

The field of applied mathematics as an undergraduate concentration on its own, has been explored by an *ad hoc* committee of CUPM, chaired by C. R. DePrima. Its report calls for still new patterns of interdisciplinary and interorganization collaboration, extending into graduate work, at least with the Society for Industrial and Applied Mathematics and the Association for Computing Machinery. Other organizations may also be involved.

12. *The problem of the college teacher.* This history has dwelt in some detail with the use of panels and reports for national organization to get at a variety of difficulties in collegiate mathematical education. The panel method is not universally applicable. In fact, in spite of the many ingenious adaptations so far devised in CUPM, the panel and recommendation procedure may be useless in getting directly into the classroom. When the doors of a classroom are shut, it is relatively insulated from outside influences which would seek to improve

what goes on there. To reach into the classroom a national organization must influence either the subject matter being studied (the course of study, the text), or the teaching medium (the teacher, film, programming of self-teaching), or the student himself. Panel recommendations do not enter the classroom. Panels cannot educate teachers, or produce films, or write textbooks, or prepare students, or select them. The critical factor in the improvement of college mathematics has apparently now become the teacher.

Instead of being overtrained for his job, with a surplus of Ph.Ds., such as we had from 1915 to 1940, the teaching staff in strictly undergraduate teaching is now in 1965 so undereducated and overloaded that CUPM recommendations may come to nothing. The college teacher needs help. CUPM did not perceive this clearly enough to adapt its patterns of activity realistically to the post-Sputnik era or to the less favored undergraduate institutions which have fallen so far behind the universities in richness of mathematical environment.

These institutions can do little to help themselves. The leading universities can no longer produce first rate Ph.D. graduates in sufficient number to help much. So it is an opportunity for great service if a national organization for the improvement of mathematical education can bring relief to the bottleneck in the educational medium, either by helping to produce more qualified teachers, or by helping the less qualified teacher to teach better, or by helping the qualified ones to teach more students.

The problem of producing a qualified college teaching staff in mathematics is to be the main concern of CUPM in the next few years. This is a manpower problem in undergraduate colleges, a graduate school problem in education, and so far everybody's and nobody's problem in the Federal government. At present CUPM regards it as a *quality* problem. For unless the qualified teachers, or some reasonable substitute, can be found the many, many young Americans who go to the colleges whose physical capacity is increased by Federal and State dollars will not get a good college education there. Our concern is for the mathematical component of that education in a society in which mathematical skills are more important than they ever were before.

CUPM has some basic preparatory work to use: the reports of its visiting Consultants, a big survey of college environments completed in 1962 for CUPM by the National Opinion Research Center at Chicago, Henry Pollak's studies of what happens to undergraduate mathematics majors when they graduate, some manpower reports on Ph.D. production in mathematics. But whatever CUPM can contribute will depend on finding radically new patterns for an organized national educational improvement group to attack this problem. That is where we are today.

STODDARD, JOHN WAGNER, ELBERT WALKER, FRED WRIGHT, JAMES H. ZANT.

THE HISTORY OF MATHEMATICAL EDUCATION

PHILLIP S. JONES, The University of Michigan

1. The Association and Mathematical Education. The inclusion of a survey of mathematical education as a part of the semi-centennial celebration of the Mathematical Association of America is appropriate for many reasons. For example, the by-laws of the Association state that one of its objectives is "to assist in promoting the interests of mathematics in America, especially in the collegiate field . . . by conducting investigations for the purpose of improving the teaching of mathematics. . . . "

In pursuit of its goals the Association has published the Carus Monographs of which the fifth, *The History of Mathematics in America before 1900*, by David Eugene Smith and Jekuthiel Ginsburg implicitly contains much of significance for the history of mathematical education in the country, especially at the college level. However, the past concern of the Association for mathematical education at the secondary level should neither be ignored nor allowed to lapse. It was particularly significant that the Association was mentioned on page one of the first volume of *The Mathematics Teacher* to be issued under the aegis of the National Council of Teachers of Mathematics. In 1921 the newly founded Council took over this journal from the Association of Teachers of Mathematics in the Middle States and Maryland. In the first issue of that year C. M. Austin, first president of the National Council, explained, in words which have a familiar ring, the needs and reasons for the founding of this new organization as follows: "During this same period (the previous ten years) high school mathematics courses have been assailed on every hand. So-called educational reformers have tinkered with the courses and they, not knowing the subject and its values, in many cases have thrown out mathematics altogether or made it entirely elective. Individual teachers and local organizations have made a fine defense to be sure, but there could be no concerted action. Finally, the Mathematical Association of America came to the rescue and appointed a committee to study the situation and to make recommendations. Already two valuable reports have been issued and others are in preparation. The pity of it is that this work, wholly in the realm of the secondary schools, should have to be done by an organization of college teachers. True, they have generously called in high school teachers to help, but the fact is that it remained for the college people to initiate the work. They could do it because they possessed a live, vigorous organization [1]. (The final report of the committee of the Association to which Austin referred was the famous "1923 report.")

It is, I believe, altogether appropriate that this Association which is still live and vigorous should continue its interest in mathematical education, not only by recognizing it in the program of this, its semi-centennial, but also in the continuing concern showed by the work of its Committee on the Undergraduate Program which has a panel on teacher training.

I was, therefore, greatly pleased when the Committee asked me to speak on

this topic which combines two of my major interests, the history of mathematics and mathematical education. The Committee neither defined these terms nor laid upon me any restrictions as to the time, period, or level of mathematical education which I should consider. I have chosen to consider education to refer to consciously and deliberately planned programs for instruction, and to attempt the task of a broad survey of the major, philosophical-psychological problems of mathematical education from its beginning until today. Such a task, of course, automatically suggests a chronological approach. But I hope that while following a chronological theme I can avoid the impression that I consider the history of either mathematics or mathematical education to be at all well embodied in a sequence of names and dates. I hope, then, that I can point out and trace with you a number of continuing and pervasive themes which I see in the teaching of mathematics through the ages. Many of the problems related to these themes are still with us, and I hope that the function of this talk may be more than a mere interesting and nostalgic review of the past. I hope that a survey of the changing objectives and philosophies of both mathematics and mathematical education can bring into sharper focus the needs and controversies of our time.

2. The Earliest Mathematical Education—Motivation. Although Seidenberg has recently elaborated a conjecture that counting originated in the rituals of prehistoric community life around 10,000 years B.C., which rituals then would no doubt have been taught to successive generations [2], our first knowledge of formal education comes from the Babylonian clay tablets and Egyptian papyri of the early historic period. The Ahmes papyrus of 1650 B. C. was copied from papyri composed as much as two hundred years earlier and gives evidence of having some of the qualities of a copybook or textbook. Not only have excavations in the Near East revealed rooms that appear to have been school classrooms, but also Babylonian cuneiform mathematical texts have, again, schoolbook properties. Scribes, clerks, and priests had to be trained to keep records associated with the calendar, land, taxation, and commerce. Amongst the problems in these ancient texts, however, one often discerns a recreational or theoretical situation such as the recently deciphered Babylonian tablet Plimpton 322 which contains a table of Pythagorean triples. So, from our vantage point in time, we can read both practical motives for formal instruction and evidence of the indulgence of intellectual curiosity in the records of the very earliest days.

However, we turn to Greece, and in particular to Athens of the 6th and 7th centuries B. C., for our first knowledge of formal schooling. In the time of Solon, the state paid tuition for the children of men killed in battle. There was a publically appointed supervisor of education, and parents were required to see that their sons were educated. There were two types of education for two classes of citizens: The liberal arts for the free citizens (here, in fact, is the origin of our word "liberal education"—an education for the free), and education in the so-called practical arts for the lower classes or slaves.

There are a number of interesting anecdotes about early Greek education that are also related to the teaching of Greek mathematics. For instance, there are two versions of the account of the first person to teach mathematics for money. One dating back to 520 B. C., says that a Pythagorean had lost his property and when this misfortune befell him he was allowed by the Brotherhood to make money by teaching geometry. Another story is that Hippocrates, of 460 B. C., who had been a merchant, was captured by pirates. Learning geometry while he was delayed in Athens by a lawsuit in which he attempted to recover his loss, he later taught it to support himself during the remainder of this time. Aristotle gives a slightly different version of this, saying that Hippocrates had been defrauded of his money because, although he was a good geometer, he was stupid and incompetent in the business of ordinary life [3]. This is the earliest citation of evidence in the perennially recurring debate as to the so-called disciplinary value of a mathematical education and its role in teaching people to think well in nonmathematical situations. In more recent times, psychologists have associated this question with the question of "transfer of training."

Pythagoras himself is the hero of the story to the effect that upon his return from Egypt he was eager to transplant to Greece what he had learned and what he had added to Egyptian mathematics. In other words, he was an eager teacher with no students. So he initially paid students the equivalent of six cents a proposition for each theorem learned. He continued this until the student was so interested and enmeshed in the intrigues of mathematics that he was willing to continue even if he had to pay rather than be paid [4]. Here, then, is a fore-taste of another current dispute; namely, does one need to foresee rather immediate profit in order to be well motivated, or can we trust to the intrinsic interest of the subject itself as motivation for the learning of our mathematics students. We have all been questioned by the student who says, "What is the good of all this?" Euclid is supposed to have answered such a question by turning to a slave and saying, "Give the student sixpence since he must need gain by what he learns" [5].

There is another problem that is classical in its antiquity and modern in its occurrence. This is the problem of the student who, impatient of proof and of the slow process of building understandings, wants the formula, the handbook, the quickly achieved result. The story is varyingly told of Alexander the Great speaking to Menaechmus or of Ptolemy speaking to Euclid. It is to the effect that the king wished to learn geometry in a hurry. The geometer's reply was, "For roads over the country there are royal roads and roads for common citizens, but in geometry there is one road for all" [6].

3. The Earliest Mathematical Education—Methods. In any event, all of the three famous Greek philosophers made contributions to the history of mathematical education. Listen to Socrates for a moment or two. This is from Jowlett's translation of Plato's *Dialogues* as quoted by J. W. A. Young who

himself deserves mention in a history of mathematical education presented to the Mathematical Association of America. After writing a dissertation in group theory in 1892, he taught at the University of Chicago where he helped to organize the Chicago section of the American Mathematical Society and became a Professor of the Pedagogy of Mathematics. His book, *The Teaching of Mathematics in the Elementary and Secondary School*, first published in 1906, went through many editions. Young chose to illustrate questioning procedures by this quotation in which Socrates is teaching a demonstration lesson. His class is an illiterate slave and his observer is Meno:

Soc. Tell me, boy, do you know that a figure like this is a square?
Boy. I do.
Soc. And do you know that a square figure has these four lines equal?
Boy. Certainly.
Soc. And these lines which I have drawn through the middle of the square are also equal?
Boy. Yes.
Soc. A square may be of any size?
Boy. Certainly.
Soc. And if one side of the square be of two feet and the other side be of two feet, how much will the whole be? Let me explain: If in one direction the space was of two feet and in the other direction of one foot, the whole would be of two feet taken once?
Boy. Yes.
Soc. But since this side is also of two feet, there are twice two feet?
Boy. There are.
Soc. Then the square is of twice two feet?
Boy. Yes.
Soc. And how many are twice two feet? Count and tell me.
Boy. Four, Socrates.
Soc. And might there not be another square twice as large as this, and having, like this, the lines equal?
Boy. Yes.
Soc. And of how many feet will that be?
Boy. Of eight feet.
Soc. And now try and tell me the length of the line which forms the side of that double square: this is two feet—what will that be?
Boy. Clearly, Socrates, that will be double.
Soc. Do you observe, Meno, that I am not teaching the boy anything but only asking him questions; and now he fancies that he knows how long a line is necessary in order to produce a figure of eight square feet; does he not?

I'll go no further with this, but note that the "Socratic method" of teaching in which students were forced to accept a conclusion, often one which differed from their original intuition, by an ingenious sequence of questions, is not the

same as modern heuristic procedures in which a student is led, sometimes by himself, to *discover* a new relationship or principle for himself. However, there are significant common elements in the methodologies of Socrates and of heuristic teaching.

Though, like Socrates, Plato was no mathematician himself, the famous painting by Raphael of Plato's Academy, a fresco to be found in the Vatican, illustrates a number of mathematical debts to Plato. I have time only to enumerate them rather hurriedly. The first of these is the concept of the academy. The picture suggests that the academy students were not young and immature, but were more nearly faculty members and graduate students. It was an early "institute for advanced study." In it, we see our first examples of group research projects and of specialization into particular subject fields of mathematics.

A second Platonic concept which has been important in the history of mathematics was elaborated in his *Republic* in which he prescribed the training for the various classes which made up the citizens of his "ideal" republic. Mathematics was a major subject in the training of the philosopher-king class in the period from age 20 to 30. The major function of this mathematics was to serve as training for the mind, for mental discipline, a goal claimed for mathematical instruction over many following centuries, and even today.

Mathematics to Plato consisted of arithmetic, geometry, astronomy, and music. These four subjects ultimately became the famous quadrivium of the Middle Ages to which were joined the three subjects termed the trivium—grammar, rhetoric, and logic, to make the curriculum which dominated education for many centuries.

Having thus seen the origins of a liberal education and of a stress on pure or abstract mathematics as the mental discipline which prepares persons to be philosopher-kings and to solve problems in all areas, it is not too surprising that we should find at this time the first major critic of mathematical education in the person of Isocrates. He criticized the concepts of over-specialization and of mathematics as a mental discipline in the following words:

> "I recommend those who are embarking on the study of geometry and astronomy to devote all their energy and intelligence to them. For I declare that, even if these disciplines cannot make better men of them, they have at least the advantage of keeping young people out of mischief; and I am convinced that no more useful or more suitable activity than these could be found for them. But at a later age, after the examinations which qualify one for the rights of an adult, I maintain that these activities are less appropriate. I would, in fact, say that some of those who have carried the study of these disciplines to the point of teaching them in their turn do not know how to put to proper use the sciences they possess and prove in all circumstances of life to be less judicious than their pupils and even—though I hardly dare suggest it—than their own servants" [7].

Aristotle also believed that the liberal education of its free citizens was essential to the building of a cohesive community and a sound state. However,

he felt that small children should gain moral and physical education through play until about the age of 14 when they were were ready for or capable of intellectual pursuits. Here, then, we find an early recognition of the problem of what is called "readiness" in educational jargon which merely asserts that the children who are too young or too ill-prepared cannot understand or profit from the study of abstractions.

4. Mathematical Education in the Middle Ages. The first treatise on educational methods can be attributed to the Roman Quintillian of 35 to 100 A.D. in a book entitled, *Institutes of Oratory*. Briefly, he argued that teachers should take into account the individual differences amongst their students, that students should be given some choice as to the topics studied, in order that their studies might more nearly coincide with the student's particular talent, that student interest was a very important factor in facilitating learning and that interest was aroused by competition and awards, not by punishment (the MAA sponsors contests!). He advocated the study of a foreign language as a device for learning one's own language and stressed mathematics strongly for its teaching of methods of proof. This, you'll note, is a slightly different objective for mathematics instruction than the disciplinary value which I have mentioned previously. Quintillian also stressed memorization as his major teaching technique without seeing anything contradictory between this teaching method and the goal of teaching methods of proof! Quintillian was rediscovered in the Renaissance and some of the blame for the stress on pure memorative learning in the universities of the Middle Ages can be placed upon him.

The monastery schools of the Dark Ages gave way to cathedral schools. As the number of students in these schools increased, it became necessary to appoint a church official to oversee them, and since the school was often in the chancel it was natural to call such a person the *chancellor*. As students organized for mutual protection against a dictatorial chancellor, their groups were called universities. Next faculties were forced to unite to protect themselves against the students, and the earliest forerunner of our modern degrees was the license to teach which also made one a member of the university of professors. The very first formal instruction in pedagogy, however, seems to have been given by the Jesuits of the 16th and 17th century to those members of their order who were going on to teach. In these centuries a double type of education began to develop. One was for middle class students who were often taught by private teachers in the vernacular and with a heavy stress on applications and the vocational uses of mathematics, especially as related to commerce, surveying, and navigation. The other type of education, for upper class students, aimed to create "Christian gentlemen," teaching them little mathematics and with a heavy stress on humanistic studies. This latter was especially true in England and Italy with more emphasis on science and mathematics in France.

However, with the Renaissance we find persons such as Roger Bacon criticizing scholastic education which stressed the reading of Latin and depended

upon memorization. Bacon suggested that more observation and study of science and mathematics should replace the narrow study of Aristotle which he felt led to a concealment of real ignorance by a pretense of knowledge.

Even the Reformation plays some role in an indirect way in the development of our subject. A heavy emphasis on so-called "original sin" very naturally led to a heavy emphasis on corporal punishment as something that was good for both mind and body. This idea of a general treatment, which was "good for mind and body" encouraged the notion of certain types of study being good "mental discipline," and thereby supported both Latin and mathematics for this purpose.

Mathematics has fared better than Latin throughout because it has been varyingly endorsed for its practical utility, for its value as mental discipline, and for its incidental teaching of methods of proof. Because of these claims for mental discipline and training in logic, it has also been stressed as an element of a liberal education. However, different aspects of mathematics were also included in the practical education of the middle class and even opposing philosophies were cited to support mathematical instruction. The philosophical materialism of Bacon and Locke which stressed learning through senses supported mathematics for its practical utility. The rational idealism of Descartes and Leibniz, which stressed that we learn through the reason, also supported an emphasis on the teaching of mathematics.

A slow change in mathematical education is revealed by a glance at some texts of the 17th and 18th centuries. The little book *Mathematicae Totius* by Pater Peter Galtrucius Aurelianensis published at Cambridge in 1683 had sections devoted to arithmetic, geometry, astronomy, chronology (the calendar) "gnomonicae" (the sun-dial), geography, optics, and music. Note that this includes the quadrivium and four additional practical topics. All this was embraced in 305 small pages! However, not to give a wrong impression, we must note that Newton, whose *Principia* appeared in 1687, had studied and taught at Cambridge and that his teacher, Isaac Barrow, had still earlier included preliminary notions leading up to the calculus in his lectures on optics, before resigning his position in favor of his promising young pupil. The ancient works of Apollonius were well known there as were the more modern works of Descartes and Fermat. However, these were not the basic fare of the secondary schools or the undergraduate curriculum.

That the elementary mathematical content of the curriculum on the continent was similar to that just displayed for England is revealed by looking at the table of contents of a *Compendium of Elementary Mathematics Composed for the Use of Young Students* by Christian Wolf of the University of Halle published in 1742. His two volumes included the eight topics of Galtrucius and then added trigonometry, mechanics, hydrostatics, "aerometria," hydraulics, perspective, "pyrotechnia," military architecture, civil architecture, and algebra in 900 small pages! Wolf also represents a growing interest in pedagogical problems which developed, especially in the German universities, at this time.

Wolf, for example, supported a lecture method as against the mere reading and exposition of a standard text which was to be memorized. He also supported the teaching of German versus Latin, allowed some electives in the curriculum, and stressed freedom for the faculty in teaching and for research.

5. The Nineteenth Century—Texts and Journals. The nineteenth century, however, was the period of real development of concern for pedagogy, educational aims and methods. The first book which I have been able to find which dealt explicitly with the teaching of mathematics was published in Paris in "An XIV" (1805). It was *Essais sur l'Enseignement en Général et sur celui des Mathématiques en Particulier* by S. F. Lacroix. In 1810 Gergonne began publication of *Annales de Mathématique Pure et Appliquée* and in the prospectus for this journal, in its first pages, he stated that "these *Annales* will be principally consecrated to pure mathematics and to all the searches which have for their object the perfecting and simplifying of teaching." However, he adds that it will also contain notes on the art of conjecturing, on political economy, military art, chronology, mineralogy, civil architecture, fortification, and the mechanic arts, together with problems and theorems to be demonstrated. These latter were to be included *"to stimulate young geometers."*

As one peruses the pages of this famous journal, he would hardly identify it as an educational journal, but would nevertheless be struck by the frequency with which mediocre and good mathematicians were publishing both short notes and longer articles of a pedagogical nature, especially, of course, dealing with expository and logical problems. For example, in the first issue Gergonne himself published an article on "the identity between the products which resulted from the same factors differently multiplied amongst themselves." This amounts to an attempt to prove commutativity and associativity for the integers without, however, using these words or recognizing these properties as axioms for an abstract system. There is also a discussion of an argument by D'Alembert and others that when an equation has two roots, one positive and one negative, the positive root actually solves the problem in a direct sense and the negative root is only a solution if the statement of the problem is modified in such a manner as to "render additive" that which was subtractive and vice versa.

There is also a proof that all similar triangles are right triangles which involves the use of the cosine law and division by a factor which would have been zero under the conditions of the problem. To this Gergonne has added an editorial note discussing and elaborating the problem of division by zero, the situations in which it arises, and stating that text book writers are most culpable not only if they make such an error but also if they fail to make a point of the difficulty explicitly.

The strength of the French influence upon mathematical education in general and upon American mathematical education in particular is further attested to by a number of additional items. Although the first journal with a

major emphasis upon the pedagogy of mathematics appears to be the *Zeitschrift für mathematischen und naturwissenschaftlichen Unterricht* founded by J. C. V. Hoffman of the Gymnasium at Freiberg and published in Leipzig beginning in 1870, France was not far behind. *L'Enseignement Mathématique* was founded in 1899 by C. A. Laisant and H. Fehr. This was the first journal devoted *solely* to the teaching of mathematics and in few years became the official journal of the International Commission on the Teaching of Mathematics which was appointed at the Fourth International Congress of Mathematicians at Rome in 1908. Laisant was also the author of one of the early books on the teaching of mathematics, *La Mathématique, Philosophie-Enseignement* (1898), but I found a book on methodology published in 1896 by Felix Dauge, *Cours de Méthodologie Mathématique*, to be most interesting. Its introduction stated that it was actually a second edition, with a different name, of a book first published in 1883 and used in a *"l'école normale"* which had since been discontinued and replaced by the inclusion of a course in methodology in the program of the doctorate in science and mathematics. Time does not permit a detailed analysis of any of these books, but since I was led to Dauge by a citation in the book by J. W. A. Young, I think it may be regarded as more influential in this country than the others. Dauge began by stressing the importance of the intimate connections among the different branches of mathematics, especially between algebra and geometry. He moved on to stress the importance of being concerned for the objectives of mathematical instruction which he puts under two categories, for applications to the needs of society and for personal careers, and secondly, for a *"moyen d'exercice d'esprit."* Dauge went on to say that actually there are only a few general precepts that can be given with reference to the teaching of any subject, that the major process of helping people to develop into good teachers is to furnish them with examples of good teaching in their classes. However, he did propose the following general rules: (1) Don't present only rigorous reasoning to youth, (2) resist sacrificing rigor to brevity in order to include more topics in the course, (3) teach fundamental principles with care but don't insist on too much abstraction nor digress too far into discussions of truth, being, and existence which will only confuse, not clarify, the mathematical concepts for students. Dauge stated that (4) at the beginning it is not necessary to prove all propositions, that it is possible to postulate those requiring more obscure reasoning or difficult proofs, that making students learn such proofs by heart does not actually make the proposition more clear. However, he stressed that (5) memory is important, that students should learn by heart some basic theorems, not only for the sake of the theorems, but to accustom the students to mathematical language and to the need to express themselves with precision and elegance. He warned against (6) extending memory, however, to the memorization of *proofs* and suggests that teachers should ask questions frequently in order to be sure that the student sees how the parts of proofs fit together. He advises that (7) when a student finds himself stopped on a proof, the professor should restrain himself from immediately pointing out the se-

quence of ideas; let the student find it for himself, an error corrected may be more profitable than several theorems proved. Other words of advice deal with very mundane affairs such as drawing clear diagrams, but also included gems of wisdom that could still be taken to heart, such as (8) do not lecture too long, the students won't pay attention and will be confused by too many terms. (9) Frame some questions to be sure that the students understand. He goes on to urge that although he had warned against consideration of metaphysical questions with the students, the professor should be informed of and concerned for such. Further, the professor should be an inspiration to the students, should not assign work that's above them, should present applications of the theory that is being developed, should sustain their attention by keeping an eye on them during his explanations, and, without departing from a proper and correct demeanor, should give proof of his good will towards the students, encouraging them with words, even for those who worked and did not succeed and punishing only in grave cases where he is certain it is needed! Above all, the instructor should maintain a spirited and zealous attitude himself.

For those who are close to current new materials in the elementary and secondary school, it is interesting to note that Dauge recommended the study of different systems of numeration in order that students might better understand the numeration system to base 10. However, he had been anticipated in this recommendation by DeMorgan in 1831 and was seconded in it by Laisant. A good share of Dauge's book, as was true of those of Lacroix, Laisant, and DeMorgan, was devoted to detailed consideration of certain typical aspects of subject matter; a favorite topic is the treatment of negative numbers, a topic of which DeMorgan wrote with great firmness. DeMorgan insisted that it was absurd to consider that any number could be less than zero. It is a little difficult, I think, for us to realize that considerable controversy over the nature of negative numbers was carried on through the greater share of the nineteenth century not only with respect to pedagogical problems, but also with respect to philosophical problems as to their very existence.

The book in which Augustus DeMorgan argued against negative numbers was *On the Study and Difficulties of Mathematics* published by the Society for the Diffusion of Useful Knowledge in 1831. This antedates all other methodological books except Lacroix. However, apart from this, the English do not seem to have been as concerned for the pedagogy of mathematics as were French and German mathematicians and educators.

DeMorgan stressed the value of mathematics as mental discipline, and an interesting feature of his essays, though not a surprising one, is his stress on the importance of teaching a unit on logic earlier in the course for secondary school students. He also made a strong plea for abolishing the rote memorization of rules and of proofs. He concluded this plea with the prediction that non-rote memoriter teaching may "excite some to become inquirers who would otherwise have been workers of rules and followers of dogma." He, too, advises teachers against entering into purely metaphysical discussions of the founda-

tions of algebra, but insists that they themselves should be alert to these and devotes some time to the absurdities of such expressions as the negative a, square root of negative a, and zero divided by zero. He ends his introduction with the statement, "The number of mathematics students, increased as it has been of late years, would be much augmented if those who hold the highest rank in science would condescend to give more effective assistance in clearing the elements of difficulties which they present."

DeMorgan does present a certain ambivalence not unknown today when in successive paragraphs he stresses that *understanding* of algebra is a most important objective which is not, however, achieved by reading but by doing, and then goes on to state, "It is a remarkable fact that the first elements of mathematics, a science which demonstrates its results with more certainty than any others, contain difficulties that have been the subject of discussions for centuries." These difficulties, he says, are not such as would suggest themselves to the beginner. The young student sees or fancies he sees the truth of every result which can be stated in a few words, or arrived at by a few simple operations. This arises, he says, from the fact that the young student from his earliest infancy learns no fact from his own observation, deduces no truth by the exercise of his own reason, and thus a habit of examination is not formed, and he is fully prepared to believe in the truth of any rule that is set before him. I hardly need point out that in 1831 DeMorgan was stressing the importance of understanding, of student derivation or "discovery" and thought as opposed to memorization.

6. Mathematical Education in the United States. Having noted some of the highlights of mathematical education in Germany, France, and England, the countries having the greatest influence on early American mathematics, it is time we considered developments in the western hemisphere and the United States. The relative recency of mathematical progress in this country may be brought out by citing a few little-known facts. The first book with mathematical content printed in the Americas was printed in Mexico City in 1556. It was Juan Diez Freyle, *Summario compendioso—de plata y ore*, which had for its major concern the treatment of the value of and conversions between different coinages of different purities of gold and silver ore. How consistent this is with the period of Spanish-American conquest and exploration! Written by a missionary, a member of a religious order, but dealing with the value of gold ore!

It is rather interesting, however, that this first book with mathematical content, aimed at this very practical problem of arithmetic, did also contain some algebra, although there was no apparent very close connection with the rest of the book or its purpose.

I will not elaborate on the other early works, but in the Western Hemisphere prior to 1700 there were 7 Mexican and 4 Peruvian books. These books, though they contained mathematics in their titles and content, dealt with military matters, with navigation, surveying, with the calendar and the determination of fast (feast) days and religious celebrations.

The first book with mathematical content printed in North America was John Hill's *The Young Secretary's Assistant*, which appeared in Boston in 1703. As its title implies, it dealt with how to write a business letter, how to keep books, etc. The secretary to the man who was sending out ships to trade, for instance between the Indies and Europe, had to know a little bit of arithmetic, of weights, measures and coinages and how to translate them into different currencies.

The first mathematics book written by a person in this country was Isaac Greenwood's *Arithmetic, Vulgar and Decimal*, printed in 1729.

The first book with any substantial geometric content was Hawney's *Complete Measurer*, printed in 1801. It dealt largely with simple surveying, weights, measures, cordwood, barrels of wine, etc.

The points are that mathematics was very late in arriving in North America, it was imported, and it stressed practical uses.

Now turning to the early schools, and their programs. The predecessor of our secondary schools was the Latin Grammar School. The Boston Latin Grammar School was established in 1635. It was a private school for a middle class clientele, preparing for the professions, ministry and law, medicine and college.

A little later we have the beginning of the academies. Benjamin Franklin founded one in 1751, but they did not really develop until sometime later, flourishing from 1787 to 1870. They were a sort of a common man's version of the Latin Grammar school. That is, they still were private, but they put a little more stress on preparation for commercial enterprises, business, etc.

About the mathematics curriculum of these grammar schools and academies I would quickly note three things: their purposes, methods of presentation, and content. There were two purposes: *practicality*, the uses of arithmetic and geometry in mensuration, calculating money in different currencies, etc., and "*mental discipline*," the idea was that it's good for your mental muscles to wrestle with Latin and arithmetic.

Their methods of presentation involved the presentation of many rules, straight-forward statements, often in italics, to be memorized, a worked example or so for each, and then problems to be done. This may be illustrated by a quotation from Quackenbos' *Elementary Arithmetic*, copyright in 1821, but used by my father in 1892. Page 78 begins the discussion of fractions as follows: "Halves and halves, thirds and thirds, etc. can be added just as we add pears and pears, dollars and dollars." That was paragraph 130 and there was just a bit more discussion in it of adding fractions with common denominators.

Paragraph 131 on the same small page read, "Halves, thirds, etc. cannot be thus directly added any more than we can add pears and dollars." This was followed by an example of how to add halves and thirds. Following the example came a rule. Following the rule, were "exercises for the slate." And that was it! On two small pages he covered adding fractions with and without common denominators, gave examples and a set of problems.

Although this procedure of stating rules, doing examples and giving exer-

cises was typical, there were, of course, persons trying to do other things. Warren Colburn wrote *Intellectual Arithmetic Upon the Inductive Method of Instruction* in 1821. I took down from my shelf his *Introduction to Algebra Upon the Inductive Method of Instruction*, which in the copy I have is dated 1830. Its preface, in part, read:

> "The first object of the author of the following treatise has been to make the transition from arithmetic too algebra as gradual as possible. The book therefore commences with practical questions in simple equations such as the learner might readily solve without the aid of algebra . . . "
>
> "The most simple combinations are given first, then those which are more difficult. The learner is expected to derive most of his knowledge by solving the examples himself; . . . "
>
> "In fact, explanations rather embarrass than aid the learner because he is apt to trust too much to the man, and neglect to employ his own power; and because the explanation is not made in the way that would naturally suggest itself to him if he were left to examine the subject by himself. . . . This method besides giving the learner confidence, . . . is much more interesting because he seems to be constantly making new discoveries . . . "
>
> "In the ninth article the learner is taught to generalize particular cases and to form rules. . . . The learner should solve every question. When the learner is directed to turn back and to do in a new way, something he has done before, let him not fail to do it, for it will be necessary for his future progress. . . . "

The content of the grammar school curriculum and the nature of beginning college work is further delineated by taking a glance at college entrance requirements. Harvard required arithmetic for admission in 1807 and algebra in 1820. Harvard was followed by Yale in 1847, and by Princeton in 1848. In geometry Yale led all the rest. It required geometry in 1865. Princeton, Michigan, and Cornell had geometry as an entrance requirement in 1868, Harvard added geometry in 1870, but when Harvard did do it they required logarithms as well.

An extract from the code of laws governing the University of Michigan in 1837 shows implicitly both its mathematics curriculum and three important influences upon early mathematics education in this country, that of (1) the French, (2) the United States Military Academy, (3) Charles Davies. The texts in mathematics listed for that year were:

Davies' *Arithmetic*
Davies' *Bourdon's Algebra*
Davies' *Legendre's Geometry*
Davies' *Surveying*
Davies' *Descriptive Geometry*
Bridges' *Conic Sections*
Gregory's *Mathematics for Practical Men*

Davies seems nearly to have made a clean sweep of textbook adoptions at the University of Michigan in 1837—(at this time I believe there were seven students!), and indeed his books were extremely popular and went through many editions. In later editions the names of Bourdon and Legendre were dropped and many people forgot that these were translations from the French, originally for use at the United States Military Academy which also brought over several

French mathematicians as teachers. Charles Davies was chairman of the department there for a number of years. As his textbooks became popular he added to them the first book on the teaching of mathematics published in this country, *The Logic and Utility of Mathematics with the Best Methods of Instruction Explained and Illustrated,* published in New York in 1857. It is interesting that, along with DeMorgan, he stressed the importance of explicit instruction in logic. The introduction to this book read, in part:

> "The following is not a series of speculations. It is but an analysis of that system of mathematical instruction which has been steadily pursued at the Military Academy over a quarter of a century, and which has given to that institution its celebrity as a school of mathematical science."
>
> "It is of the essence of that system that a principle be taught before it is applied to practice, . . . the union of the French and English systems of mathematics. . . . "

7. Foreign Influences on Mathematical Education in the United States. However, I should not overemphasize the French influence upon American mathematical education. In methodology Colburn was influenced by a Swiss educator, Pestalozzi, although the French also played a part in the spread of inductive methods. As recently as 1920 the title page of an arithmetic book of which John Dewey was listed as an author bore the following quotation from Laisant, who was a Belgian:

> "The problem is always the same: to interest the pupil, to induce research, to give him the notion continually, the illusion if you please, that he is discovering for himself, that which is being taught him."

Further, although all American mathematicians know something of Felix Klein, many may not fully appreciate his rather direct effect upon American mathematics. I refer to the effect upon graduate study and research of his presence in this country for the Congress of 1893 and the colloquium at Evanston which followed, and also the publication in this country of his pedagogical volumes, *Elementary Mathematics from an Advanced Standpoint* in a translation by one of the Association's founders, Earle Raymond Hedrick. Finally, in this later period we need to consider the effects in this country of the reform movement in Britain. In particular, E. H. Moore, who spoke out strongly for reform in mathematical education in his American Mathematical Society retiring presidential address in 1902, was greatly influenced by John Perry. For the background of Perry's views I quote from a recent pamphlet from the British Ministry of Education, *Teaching Mathematics in the Secondary Schools,* which states, "Mathematics hardly existed in schools until the time of Queen Victoria, whose reign began in 1837."

In 1861 The Royal Commission on Nine Public Schools said, "The chief honors and prizes in our public schools go for the Classics which are to the great number of the boys, intrinsically more attractive than Mathematics . . . but mathematics, at least, has established a title of respect as an instrument of mental discipline." Another quotation from this same group refers to a situation which has been much more significant in England than in this country, but it

may become increasingly significant in this country. This is the relationship between the secondary schools and the college entrance examinations, or as they are called in this report, "the external examinations." The quotation is, "The introduction of mathematics as an integral part of the school curriculum coincided with the establishment of external examinations. This circumstance tended to set a pattern of mathematics education before much thought had been given to the matter." The curriculum in England at that time included algebra, geometry, surveying, navigation, mensuration and trigonometry.

Following this, toward the end of the 19th century, student failures in mathematics and Latin increased and colleges complained of the poor preparation of their students.

These quotations and facts point out the following "morals": (1) College criticisms have motivated establishing and changing external examinations which in turn have very significant effects on the school curriculum. (2) The changing nature of the school population has also been a factor in the design of school programs. (3) Practical and intellectual objectives have always had a place in our school programs, but have varied in their relative importance.

John Perry spoke in 1901 to the British Association for the Advancement of Science in England, and out of his speech came a committee that reported a year later. Its report did make significant changes in the examinations and syllabus for geometry in England in the direction of allowing more flexibility in answers rather than reproduction of Euclid. I'm not going to go into that, but among Perry's own emphases were: the use of the laboratory method of teaching, stress on the correlation between mathematics and science, acceptance of some theorems without proof, and discussion of practical uses.

I cannot resist the temptation to read to you a quotation from this discussion in 1901. You will be interested that among persons who contributed to this discussion, either written comments or through their own presence, were Mrs. Boole, Miss Scott from Bryn Mawr, Horace Lamb, David Eugene Smith, Lord Kelvin, and Oliver Heaviside. Here is the quotation from Heaviside:

> "Boys are not philosophers and logicians. . . . Now the prevalent idea of mathematical works is that you must understand the reason first before you practice. This is fuss and fiddlesticks. . . . I know mathematical processes that I have used with success for a very long time of which neither I nor anyone else understands the scholastic logic. . . . There is something wanting, no matter how logical people may pretend. . . . Geometry should be entirely observational and experimental at first. . . . "

I hardly need note that this attitude has its modern advocates.

8. More Recent Developments in the United States. J. W. A. Young called it a remarkable coincidence that a marked impetus toward reform was given in two countries, in two successive years, in addresses before major scientific bodies, Perry in 1901, and E. H. Moore in 1902. Moore called for more "fusion" or "correlation" between mathematics and other subjects, especially science, and for more concern for concrete and developmental work in teaching in the secondary schools.

In addition to these events and the "1923 report" [8] noted earlier there were other landmarks in the progress of mathematical education in the United States in the twentieth century. Some of these were: 1894—the Committee on College Entrance Requirements; 1911–1918, the International Commission on the Teaching of Mathematics. The almost tumultuous progress of the past decade was anticipated by the activities of the Commission on Post-War Plans of the National Council of Teachers of Mathematics which operated from 1944–1947. Recent vigorous activity was then touched off in 1952, prior to Sputnik, by the publication of a report *General Education in School and College* by a committee from three eastern colleges and nearby preparatory schools, and the founding of the University of Illinois Committee on School Mathematics. Although the current N.S.F. institutes were anticipated by summer programs for secondary school teachers at Duke University, 1953 marked the beginning of National Science Foundation support with the Summer Conference on Collegiate Mathematics held at the University of Colorado.

However, I have chosen in this talk to slight these developments of the twentieth century and the last decade, because they are familiar to many, and the literature on them is adequate and reasonably available [9]. I have preferred to use my time to present a longer range point of view. But, since this is the semi-centennial celebration of the Mathematical Association of America, and since some of its charter members present here today were active in the second of two projects it sponsored which were of great significance for mathematical education, I believe a bit more should be said of these two reports.

In 1923 the National Committee on Mathematical Requirements of the Mathematical Association of America, which was appointed by E. R. Hedrick in 1916, brought in its famous report after seven years of work. It classified the objectives of mathematical instruction as practical, disciplinary and cultural, and stressed the role of the function concept in the teaching of mathematics. Most texts for years thereafter cited this report in their prefaces and honored the then current interpretation of the "function concept" by stressing the interrelationships between tables, graphs, formulas, and equations. Its stress on the function concept and general mathematics reflected the influences of Felix Klein and E. H. Moore respectively. The representatives of the Association on this Committee were: J. W. Young, A. R. Crathorne, C. N. Moore, E. H. Moore, D. E. Smith, H. W. Tyler. The other seven members of the committee represented secondary school teachers and organizations.

Two groups reported in 1940. One had been appointed by the Progressive Education Association, and the other was the Joint Committee of the Mathematical Association of America and the National Council of Teachers of Mathematics appointed to study the place of mathematics in secondary education.

The first group expounded a long range philosophy. They stressed the importance of teaching problem solving and the nature of mathematical structure and wrote about data, approximation, function, operation, proof, and symbolism.

This report suffered some in its influence for being associated with the Progressive Education Association, I believe. There were many very good and rather modern ideas in the report.

The Joint Committee had the same number of representatives from the Association as from the National Council. The Association representatives were: K. P. Williams, A. A. Bennett, H. E. Buchanan, F. L. Griffin, C. A. Hutchinson, H. F. MacNiesh and U. G. Mitchell.

The Joint Committee stressed individual differences. It recommended a two or more "track" curriculum. This was again a product of the time, the condition of the schools, and the condition of mathematics in the schools. They also wrote about transfer of training. The notion of transfer of training was for a time substantially discredited by psychologists. It is now beginning to be regarded again as an important educational element but with several theories, some new, to describe and explain it and the conditions under which it takes place.

In conclusion, I have omitted much: (1) the names of many writers whose accounts I have read, (2) expositions of the reports of some famous committees which I listed and others which I did not list, (3) an elaboration of the role of the Mathematical Association of America in mathematical education.

I hope that my recurring reference to recurring themes was not too boring and, more important, not misunderstood. I do *not* mean to imply that there is nothing new in mathematical education (although it is a pity how often truths have to be rediscovered before they can be extended and applied). I *do* mean that looking at how fundamental ideas and perceptions have changed may shed light on the future and suggest what are the real invariants in good mathematical education.

For example Euclid's geometry and modern Euclidean geometry both are based on axioms and definitions, *but* the modern view of the nature and source of these and the connections between them and the physical world is significantly different from Euclid's. I think Newton may have had some concept of the relationship between the physical world and a mathematical model, *but* I don't believe that his view was our view. I believe that students may be brought to understand axiomatics and mathematical models better if they are shown something of their growth and the changing nature of our perceptions of them.

Similarly, today mathematical education is faced with many important problems which are not essentially new, but which, likewise, are not merely the same old ones out of which they developed. Some of these are:

(1) What are the *objectives* of mathematical instruction? We need to recognize that they are not the same for all and that our school population includes *all.*

(2) What is the *role of applications* and *physical models* in both clarifying and motivating instruction?

(3) What is the *level of rigor* which is sound and desirable at different stages of the student's development?

(4) How do we *teach the excitement and beauty* of mathematics, as well as its theorems?

(5) Can we teach students to *discover* or to be more creative?

(6) What are *the relative roles of intuition, induction and deduction* and how do we communicate them?

I hope a historical survey of these continuing themes may direct and stimulate your thinking and suggest that there will always be a continuing problem of cooperating to adapt our curricula and teaching procedures to the changing philosophies and definitions of mathematics itself, as well as to the changing needs of our culture—both intellectual and practical, and to our uncertain but growing knowledge of the psychology of learning, applying, and extending knowledge.

CHALLENGING CONJECTURES

R. H. BING, University of Wisconsin

1. Importance of research to teaching. Mathematics is an alive and growing subject. It is best taught by teachers who are mathematically alive and mathematically growing.

The editorial in the June 18, 1965 issue of *Science* was entitled "What Are Professors For?" It says that the professor's primary activities should be teaching and research. Concerning the teaching portion of his duties the editorial has this to say, "If transfer of information were enough, society could dispense with most professors and education could be almost completely mechanized. The professor's most important role is to provide various forms of guidance for the students. As a result of his university experience, a student should be motivated to pursue continuing scholarship throughout his life."

Motivated to pursue continuing scholarship! If the teacher himself does not pursue continuing scholarship, how effective is he in encouraging his students to do so?

If the teacher pretends to be interested in getting solutions to difficult problems, pretends to be interested in proving challenging theorems, pretends to be seeking knowledge, pretends to have an inquiring mind—how many students are dumb enough to be fooled by the fakery if the teacher is merely pretending but in fact is resting on his background?

The effective teacher is the one who moves ahead. He should not be like the little boy who asked his mother, "Why do I always go around in circles?" and gets the reply "Shut up or I'll nail your other foot to the floor." The teacher should move ahead on two feet—both in teaching and in acquiring mathematical proficiency.

There has been much publicity given recently to the emphasis on research to the extent that teaching is neglected. The layman is disturbed by this. A recent article in the *Reader's Digest* was entitled "Is There a Teacher on the Faculty?" University and college people are less frightened because they know that most researchers do teach and are all the more effective as teachers because of their research experience. We occasionally hear of fellowship bums and those who shun teaching to get contracts. My experience suggests that there is relatively little of this abuse. If it were widespread it would be most unfortunate since those working at the frontier can be and frequently are our most effective teachers. Mathematicians as a whole are an energetic, intelligent, dedicated lot who try for original results themselves but who also see teaching as a way of promoting mathematics.

Let us look at the other side of the coin. It is most unfortunate for the teaching profession when the professor goes to sleep.

The slogan "Publish or Perish" might be interpreted to suggest that the teacher who does not make progress in contributing to knowledge by discovering new mathematical truths or finding new uses of mathematics loses his effective-

ness as a mathematics teacher. Recent institutes for college teachers have turned up examples of teachers who have not kept up and have practically perished mathematically.

One of the important innovations of the last decade has been the massive fellowship and grant programs instituted to stimulate more research and better teaching. Governmental agencies such as the National Science Foundation, Office of Naval Research, Air Force Office of Scientific Research, U. S. Army Research Office, evidencing the nation's concern that the United States obtain and maintain a position of scientific leadership in the world, have developed fellowship and grant programs. Public-spirited private foundations such as the Sloan Foundation, the Ford Foundation, the Research Corporation, the Carnegie Corporation, the Rockefeller Foundation, the Guggenheim Foundation, I.B.M., Bell Telephone, U. S. Steel, and others have made valuable contributions.

Many of these programs were aimed at promoting more and better research but a side effect has been that we are getting better teaching. Of course, even those programs aimed at better teaching will eventually result in more and better research. Thanks in a large measure to these fellowship and grant programs and to the leadership and hard work of many of you, I believe that we are providing students in the United States today with the best mathematical training that any group has ever had in our history.

There is room for improvement and we should continue to move ahead. In particular I hope we find better means of keeping the younger faculty of our smaller colleges active. Experience has shown that it is far easier to keep working people alive than it is to resurrect the dead.

Although doing research and finding new applications of mathematics are perhaps the most interesting ways of working at mathematics, other means of maintaining mathematical vigor include keeping acquainted with new developments in mathematics by reading mathematical articles, attending seminars, participating in the development of new curricula and teaching techniques, solving mathematical puzzles and problems, and coaching mathematics teams. The two publications *Mathematics Magazine* and *The American Mathematical Monthly* put out by the Mathematical Association of America can be of help in pursuing some of these activities.

In the better schools, teaching and research move forward hand in hand. That mathematics is an alive and growing subject makes it interesting from the standpoint of both teaching and research. Research acts as a leaven—as a catalytic agent that improves the whole loaf.

Let us look at some challenging conjectures that have stimulated much mathematical thought. We shall take a brief look at each of the following:

Continuum hypothesis.
Normal Moore Space conjecture.
Fixed point conjecture for cellular plane sets.
Poincaré conjecture.
Annulus conjecture.

2. Continuum hypothesis. Perhaps the oldest of these conjectures and the one to which most thought has been given is the continuum hypothesis—which is that C is the first uncountable cardinal.

I would like to discover whether one could prove on the basis of a reasonable set of assumptions that for each uncountable subset X of the Euclidean line E^1 there is a 1-1 correspondence between the points of X and the points of E^1, or whether there is some uncountable subset of E^1 for which there is no such correspondence.

There have been some very interesting theorems by Paul Cohen and others showing that these questions cannot be answered in certain restricted logical systems. This reminds us a bit of the situation in which Euclid and his associates were unable to prove certain theorems without the Parallel Postulate. However, these logical systems which have been shown to be inadequate to handle the continuum hypothesis have countable models and axiomatic systems based on these logical systems do not purport to describe adequately the working model of the real number system as I and many other mathematicians envision it. When I ask if these things can be proved on the basis of a reasonable set of assumptions, I do not know what these might be but would hope to include only things that would be viewed by many as "self evident truths" and not use assumptions as far fetched as the continuum hypothesis itself.

For example, I would be quite willing to have as one of my reasonable assumptions the assertion that any uncountable subset of E^1 is intrinsically uncountable—it is uncountable, not merely because one does not have a handy effective way of setting up a 1-1 correspondence between it and the integers, but rather, it has so many points that even with additional consistent assumptions, there is no such 1-1 correspondence. Not everyone would agree to this assumption, but enough do to meet my criterion of reasonableness.

Also, I would regard the "integers" as a well defined set on which most mathematicians agree even without axiomatization, rather than things satisfying certain noncategorical systems. Similarly, I regard the "reals" and E^1 as fixed, invariant, agreed upon sets. These viewpoints do not lend themselves well to systems with countable models where any uncountable set is at best conditionally uncountable, rather than intrinsically uncountable. It would be interesting to know if one steps outside these abstract "reals" with countable models and into the real reals, whether or not the continuum hypothesis is true.

3. Normal Moore space conjectures. The normal Moore space conjecture perhaps stands with one foot in Foundations and the other in Topology. It suggests that a certain set of conditions imposed on a topological space is enough to insure that the space is metrizable.

The notation of a distance is important in geometry, analysis, and topology—but its meaning in analysis and topology is slightly more abstract than its meaning in geometry. We note that to each pair of points x, y of a Euclidean space there is associated a number $D(x, y)$ called the distance between x and y, satisfying the following conditions:

1. $D(x, y) \geqq 0$, the equality holding if and only if $x = y$.
2. $D(x, y) = D(y, x)$ (symmetric condition).
3. $D(x, y) + D(y, z) \geqq D(x, z)$ (triangle inequality).
4. D preserves limit points. The last condition means that p is a point of the closure of a set X if and only if $D(p, X) = 0$.

These conditions alone do not furnish us with all the properties of a Euclidean distance, any more than a set of axioms for the reals based on a countable model of set theory gives a complete picture of the reals as mentioned in the discussion of the continuum hypothesis. However, the properties are powerful enough to be useful in proving many theorems and in getting some counterexamples.

A topological space with a distance function has a sequence of open coverings such that the meshes of the open coverings approach zero. Such sequences of open coverings are very useful in studying topological spaces since they provide us with means of proving theorems, building arcs, approximating the space with polyhedra, and computing certain algebraic properties of the space.

In his book, *Foundations of Point Set Theory*, R. L. Moore takes as axiomatic the condition that a space has a decreasing sequence $G_1, G_2, \cdots$ of open coverings. He does not assume a distance function so cannot discuss the meshes of the coverings, but uses a substitute. He does this by supposing that if N is a neighborhood of a point p, there is a covering G_i of the sequence of coverings such that each open set in G_i which contains p lies in N. A regular Hausdorff space with such a decreasing sequence of open coverings is called a *Moore space.*

A Moore space has many of the properties of a metric space and many theorems about metric spaces can be proved equally well in such a space. There are examples known of Moore spaces which do not have a distance function since they are not normal—that is, they contain two mutually exclusive closed sets which do not lie in mutually exclusive open sets. Such an example is given by the following flow space.

Suppose water is flowing across a square at a varying rate—say varying

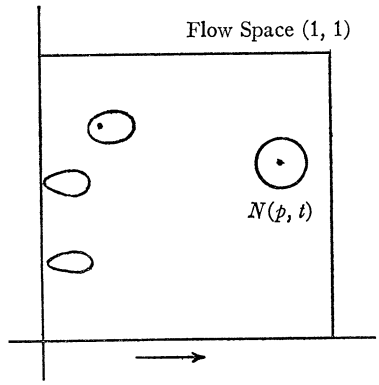

FIG. 1. (rate $= 1 - x$)

linearly from one foot per second on the left to zero on the right. Points of the flow space are points of the square and for each point p of the square and each $t>0$, $N(p, t)$ is the set of all points of the square to which one could swim from p in time less than t if one swims at a rate of one foot per second. The $N(p, t)$ neighborhoods on the right of the square are nearly round while those on the left are oblong as shown in Figure 1.

No two points of the left side of the square belong to the same $N(p, t)$. It may be shown that the square whose basis of neighborhoods are the $N(p, t)$'s is a Moore space. It is not normal because if one takes as A and B, the rational and irrational points on the left side of the square, these are mutually exclusive closed sets which do not lie in mutually exclusive open sets.

Many research hours have been spent in trying to decide if each normal Moore space is metrizable. Partial solutions have been given. Just as the continuum hypothesis has been translated into equivalent problems, the normal Moore space conjecture has been translated. In the August 1965 issue of the *Proc. Amer. Math. Soc.*, I show relations between the conjecture and the existence of certain functions from abstract sets into the positive integers. Because of such considerations, the normal Moore space conjecture lies partially in Foundations and partially in Topology.

4. Fixed point conjecture for cellular plane sets. A straight line segment has the fixed point property in the sense that if f is a map of I^1 into I^1, then some point of I^1 goes onto itself under f. To see why this is true, one can consider I^1 as horizontal and let R be the set of points of I^1 that move to the right under f and L be those which move to the left. If there is no fixed point, the left point of I^1 is in R and the right point in L. It may be shown that each of L and R is open in I^1. Since I^1 is connected, it is not the sum of two non-null mutually exclusive open sets. Hence there is a point of I^1 in neither R nor L. This point is left fixed under f.

It may also be shown that a square has the fixed point property. If one were to pick up a piece of paper, wad it up, and drop it back on the spot where it lay, there would be some point directly above where it once was.

Cells of all dimensions are known to have the fixed point property.

A set is cell-like if it is the intersection of a decreasing sequence of topological cells. There are many properties that are inherited in the sense that a set has the property if it is the intersection of a decreasing sequence of sets with the property. Being closed and being compact are such properties. People once wondered if the fixed point property was such an inherited property. They now know that it is not.

However, it is still unknown whether or not a set X in the plane has the fixed point property if it is the interesection of a decreasing sequence of topological disks. I have received papers to referee in which erroneous proofs were given. I saw a preprint of another paper giving an erroneous counterexample. Once I attended a lecture in which the speaker was giving a proof and as a result of a question from the audience during his talk, he stopped his talk because the

question uncovered a flaw. It is a tantalizing question because it seems that an answer should be available.

In 1948 Borsuk discovered an example of a set which did not have the fixed point property even though it was the intersection of a decreasing sequence of topological cubes. Here is another example.

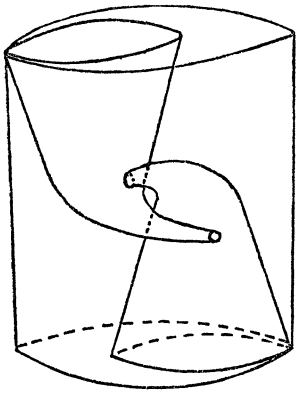

FIG. 2

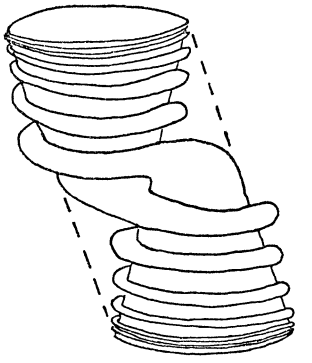

FIG. 3

Start with a solid cylinder as shown in Figure 2. Bore a hole from the top, a hole from the bottom, and whittle away at the sides. Finally, have left a set like that shown in Figure 3. The horizontal cross sections of the ends are circles and other horizontal cross sections are the unions of tangent circles. The set of points of tangency spirals about the bottom circles and about the top circle. It is what one would obtain by taking two cones, one right side up and the other upside down and sewing them together so that the vertex of one spirals around the base of the other as shown in Figure 4. To get a map that leaves no point fixed,

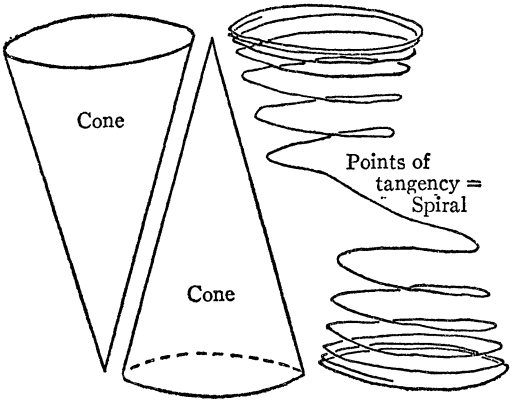

FIG. 4

one merely needs to insist that the top circle goes onto itself under a rotation, the bottom circle goes onto itself under a rotation, and each other horizontal cross section goes onto a slightly higher cross section.

5. The Poincaré conjecture. In high school geometry we work with a set of axioms that characterize the plane. In this spirit it is of interest to consider sets of conditions such that Euclidean 3-space satisfies these conditions and any topological space which satisfies the conditions is topologically equivalent to Euclidean 3-space. The Poincaré conjecture gives a set of conditions that appear to some to be enough to insure that any topological space satisfying them would be topologically like closed 3-space—that is Euclidean 3-space with a point added at infinity to make it a 3-sphere.

The Poincaré conjecture perhaps arose as a result of a mistake. In 1900 Poincaré announced that any two n-manifolds were topologically alike if they had the same homological properties. He perhaps indicated a proof, but it was in error since he showed in a 1904 paper that there is a 3-manifold with the same homological properties as a 3-sphere but which is topologically different.

Homotopy properties are stronger than homological properties but in 1919 Alexander showed that there are lens spaces with the same homotopy properties that are combinatorially different. As a result of some more recent work of Moise we now know that these lens spaces are topologically different.

There have been many false solutions to the Poincaré conjecture—most of them never reached print. One by Whitehead appeared in 1934, but he made a retraction in 1935. I gave a partial solution in 1958 when I showed that a stronger condition than that stipulated in the Poincaré conjecture was enough to insure that the space actually was topologically a 3-sphere. For a while it looked like I might withdraw my paper since it was rumored in 1957 that both Moise and Papakyriakopoulos had complete solutions. Naturally, I did not wish to publish a partial solution if others got the whole thing. Both of their proofs sprung leaks.

In 1957 Poenaru wrote a long paper trying to give a solution but an error was discovered in his proof by the referee of a journal and it did not reach print. Koseki published a long proof in 1958 but the proof is not clear at one crucial spot.

Last summer, it appeared that each of Haken and Poenaru might have solutions. Although each tried novel methods and got interesting results, neither actually got a solution to the Poincaré conjecture.

The precise statement of the Poincaré conjecture is that a compact connected 3-manifold is topologically a 3-sphere if it is simply connected. We shall not discuss it further, but those interested in its history and various partial solutions of it might find of interest the chapter entitled "Some aspects of the topology of 3-manifolds related to the Poincaré conjecture" in volume II of *Lectures on Modern Mathematics* (Wiley, New York, 1964). Any set homeomorphic to an annulus is called an annulus.

6. The Annulus Conjecture. The closure of the part of the plane between two concentric circles is called an annulus. Generalizing this notion we say that the closure of the part of E^n between two concentric $(n-1)$-spheres is an n-dimensional annulus.

Suppose S is a smooth $(n-1)$-sphere in E^n and h is a homeomorphism of E^n onto itself such that $h(S)$ lies in the bounded component of E^n-S. Although $h(S)$ may not be smoothly embedded, it has a Cartesian product neighborhood since h is a space homeomorphism. Is the closure of the part of E^n between S and $h(S)$ an annulus? The answer is yes if $n=1$, 2, or 3. These are precisely the dimensions in which we can triangulate manifolds. If we knew how to prove the annulus conjecture for $n\geqq 4$, this would be useful in studying higher dimensional manifolds.

The annulus conjecture has been shown to be equivalent to other hard conjectures. False solutions to it have been proposed and submitted for publication, but so far as I know, no solutions (false or otherwise) have appeared in print.

7. Mathematics moves forward. The conjectures we have discussed are difficult and it is only infrequently that problems as difficult as these are solved. In fact, perhaps as many will be settled by counterexamples as by proofs. I have a feeling that most topology theorems that are true are true because of some simple underlying geometric principle. If there is such a principle we may write a clumsy complicated proof at first but once the underlying principle is understood, the proof clears up. If there is no such easy underlying geometric principle, the chances are that the conjecture is false.

Although the above conjectures may be hard to solve, I believe it is fruitful to ponder them. Good results are often found when one is looking for something else. With more space I could point out many interesting results that were obtained in unsuccessful attempts to answer the preceding conjectures.

Today, new results are being proved at an increasing rate but these proven theorems reveal many interesting things yet to try. As evidence of the amount of research being done I mention that in 1964 over 1200 abstracts were presented at various meetings of the American Mathematical Society.

Of course, only a fractional part of the mathematical research being done in the world is done in the United States. *Mathematical Reviews* which summarizes papers from all over the world reviewed 7000 papers during the first six months of 1965. Estimating the average length of a research paper to be 10 pages (some are much longer and some shorter) this comes to 140,000 pages of mathematics a year—more pages than many students read in an entire college career. I would not suggest that you read much of it. It contains few expository articles or textbooks. Most of the review articles are concerned with careful proofs, new methods of doing things, new applications of mathematics, reasons why certain things are true.

One nice thing about working at mathematics is that you do not need to

know everything about everything. You should have a solid background, and if you are to work successfully at the frontier you need to know almost everything about something.

For those students who follow mathematics as a career, I hope we can get more of them to remain mathematically active. To train them properly we need teachers with mathematical vigor who will remain learners.

I have heard that when learning ceases, rigor mortis sets in. Whether or not this is true, I feel that our schools today are turning out too many finished people—people whose learning is essentially finished when they graduate.

In the United States today there is a need for scholarly people: those who will remain students, scholars, learners, thinkers after college—teachers who can devise and teach a different and better course than they were ever taught.

The progress of our country depends in a large measure on active people. Our most effective teachers are the sort of people who subscribe to professional journals, participate in mathematical activities, read, think, ponder, plan, forge ahead. They work at mathematics whether it be at solving problems in the *Monthly* or doing profound mathematical research.

This is a good day to be a mathematician and teacher. Things are moving. There is excitement and controversy. Changes are being made. The rewards are better than ever before.

But on the other hand, more is expected of us. The high school teacher is supposed to teach not only the facts of mathematics but also an understanding of why these facts are true. It is hoped that the college teacher will impart not merely facts and understanding but also a glimpse of the charm and challenge of mathematics.

I wish you success in leading your better students to see the beauty of mathematics, to give them a taste of the type of mathematics that grips a mathematician's interest, tugs at his imagination, and makes him willing and eager to work long and hard to get a result that challenges him.

We realize that most students will not be research mathematicians, most will not reach the frontier—but they appreciate mathematics more if they know that the frontier is there, know that it is not inaccessible, get an occasional glimpse of it, and realize that it is being pushed back—sometimes steadily but often spasmodically.

Mathematics is not merely a subject of the past, but it is an alive and growing subject. It is not just a subject for the exceptional genius but it is a subject with a challenge for all of us.

TRENDS IN ANALYSIS

E. J. McSHANE, University of Virginia

1. Introduction. Before I begin on the subject matter of this talk, I wish to explain the sense in which it will live up to its title. First, I shall not try to discuss recent important advances in analysis. The "Mathematical Reviews" is being published at a rate that threatens the shelf-room of everything else in my mathematical library, and nearly half of it consists of reviews of papers on analysis. If I tried to describe the thousandth part of these in one hour, I could not hope to do so intelligibly. Nor would this be appropriate for a meeting of the Mathematical Association of America, which is concerned with the teaching of mathematics rather than with the latest mathematical research. Of the recent mathematical discoveries, any one student can be taught only a small part. But whatever we teach, we teach from some point of view and with some mental attitude, and what the student learns from us about mathematical thought-patterns will long outlast the individual mathematical facts that he picks up. I intend to speak about the changes in the prevailing points of view in analysis that have taken place since this Association was founded.

The most conspicuous trend in analysis, as well as in most other parts of mathematics, during the twentieth century, may be said to have started twenty-two centuries ago, with Euclid. It was he who made a coherent logical structure of the mathematics of his time, analyzing the assumptions needed to establish the theorems of geometry. But in the development of mathematics in the eighteenth and nineteenth centuries such an analysis of structure was largely ignored. There was then much more interest in acquiring new facts, in discovering interesting properties of special functions and inventing new methods of solving rather specific problems. But today the tendency is to consider large classes of mathematical objects that exhibit some common properties and to investigate to find the common structural elements that produce the common properties. Often we find that among the mathematical objects sharing the common properties there is some old acquaintance from familiar geometry or algebra. Then we usually choose a terminology suggested by that familiar example. This helps to remove the boundaries between the different fields of mathematics, and thus to unify the subject. More than this, by emphasizing the similarities between less familiar objects and those whose properties are well known to us, it helps us in reasoning about the new objects. As an example of what I mean, among the most conspicuous properties of vectors in finite-dimensional spaces are the linear properties; the vectors can be added, subtracted and multiplied by numbers in a way familiar to all of us, but many other collections of objects can be added and subtracted and multiplied by numbers just as those vectors can. When we wish to study the additional properties of such collections that are closely related to the linearity properties, we call the collection a "linear space," and the analogy with elementary geometry is a guide to our reasoning.

I do not at all intend to suggest that all good mathematical papers, or even the majority of them, are devoted to this sort of analysis of structure. Perhaps a majority of today's published papers in analysis could be read by Cauchy, if he could return from the grave and if the literary style of contemporary writing did not drive him back into it. It is well that this is so. It was about thirty years ago that Hermann Weyl warned that we had been living for a long time on abstracting and generalizing the special examples that our grandfathers had found, and that the continued life of mathematics required finding new interesting examples. There is not much profit in finding a common generalization of several mathematical objects whose chief common property is dullness. But when several somewhat similar special cases have been developed, or when one strikingly new instance appears, we may count on it that several of us will soon be busy trying to find just what it is that is essential in the situation.

One strong incentive toward the development of the concept of linear spaces was the great interest in integral equations about the turn of the century. It was evident that the classes of functions being studied had the linearity properties of vectors in finite-dimensional spaces, and that their transformations by means of integral kernels strongly resembled the transformations of vectors by means of matrices. Ehrhard Schmidt, for example, published his researches in a geometric terminology practically the same as that most favored today. At about the same time Fréchet, F. Riesz and Hausdorff were developing point-set topology and introducing the concepts of metric and norm and completeness and many others that we now expect any beginning graduate student to have at his finger-tips.

2. Lebesgue Integrals. In 1904 a new element of huge importance made its appearance. This was the Lebesgue integral. If by R_2 we denote the set of functions f on $[0, 1]$ such that f and $|f|^2$ are Riemann integrable, and define

$$\|f\| = \left[\int_0^1 |f(x)|^2 dx\right]^{1/2},$$

this becomes a normed linear space (provided we identify functions f, g for which $\|f-g\|=0$). But it is not complete; Cauchy sequences in R_2 exist which have no limit in R_2. Nor is the situation improved if we allow "improper" Riemann integrals, permitting, say, finitely many infinite discontinuities of the integrand. With the Lebesgue integral it is different; the corresponding space L_2 is a complete normed linear space. This alone, without the other advantages of the Lebesgue integral, would have made it valuable.

The completeness of the space L_2 is a mathematical fact, and is proved by logical processes. But the reason for the great success of the geometrization of function spaces is that mathematicians use logic only in the final stages of their research. Before a mathematician tries to prove something, he must conjecture that something; before he succeeds in proving it he must have decided on some pattern of proof, ordinarily pieced together from familiar devices. Less formally,

he needs good hunches before he knows what he wants to prove, and he needs good tricks to make a proof. The big help offered by thinking of function-aggregates as linear spaces is that it immediately offers analogies out of geometry, and provides mental pictures that help to suggest both the theorems and their proofs. To give a familiar example of what I mean, let us consider Fourier series of functions in L_2. In L_2 (I now allow complex-valued integrands) we can introduce an inner product

$$\langle f, g\rangle = \int_0^1 f(t)\overline{g(t)}dt$$

which strongly resembles the inner product of vectors in Euclidean spaces. The functions

$$e_n = (e^{2\pi nit}: 0 \leqq t \leqq 1) \qquad (n = 0, \pm 1, \pm 2, \cdots)$$

have norm 1:

$$\|e_n\| = \langle e_n, e_n\rangle^{1/2} = 1,$$

and any two of them have inner product 0, so they are analogous to orthogonal unit vectors in Euclidean spaces. The Fourier coefficients

$$a_n = \int_0^1 f(t)e^{-2\pi nit}dt = \langle f, e_n\rangle$$

are the components of f along these axis-vectors. Whether we use the Riemann integral or the Lebesgue, it is rather easy to prove that if f and $|f|^2$ are integrable, a generalization of the theorem of Pythagoras holds:

$$\left[\sum_{n=-\infty}^{\infty} |a_n|^2\right]^{1/2} = \|f\|.$$

Analogy with finite dimensional spaces would suggest that if $\sum|a_n|^2$ is finite, then $\sum a_n e_n$ should represent a function with finite norm whose Fourier coefficients are the a_n. But since this is an infinite series there is a limit process involved, namely taking partial sums

$$\sum_{n=-N}^{N} a_n e_n$$

and letting N tend to ∞. These partial sums form a Cauchy sequence in L_2, and because L_2 is complete they have a limit f in L_2, and this is readily shown to be the function we were seeking. The completeness of L_2 was crucial in the analogy between L_2 and the Euclidean spaces. No such close analogy with R_2 exists; in fact, in the study of Fourier series in the nineteenth century no such geometric picturization would have been at all likely to occur.

3. Abstract Linear Spaces. The popularity of Banach's famous book helped to make practically a commonplace of the ideas of abstract linear spaces and linear operations on them, with their concrete realizations in terms of aggregates of functions and operations defined chiefly in terms of summation or integration. It would be difficult to overestimate the impact of these ideas on contemporary analysis. When studying an unfamiliar class of functions it is now natural to establish its possession of at least some of the properties that have proved important in previous research. This done, it is to some extent classified, and one is thereby practically commanded to show that it has other properties that its congeners are known to possess.

It has been suspected that this sort of highly abstract mathematics is ill suited for use in applications. Whether a mathematical theory is or is not applied depends less on its content than on the mathematicians concerned. Now it may be true that there is a positive correlation between an interest in abstraction and a disregard for applications; this would be hard to prove or disprove. However, the correlation is certainly not 1.00. Consider for example the situation in quantum theory forty years ago. New experimental facts could be fitted into the Bohr theory only by wild contortions. Then Schrödinger and Heisenberg almost simultaneously developed new theories that were much more satisfactory, but unfortunately appeared very different from each other. Schrödinger used partial differential equations, Heisenberg used matrices (infinite matrices, but handled as though finite). A reconciliation or a choice had to be made for the sake of advancing. In 1929 John von Neumann settled the question by introducing abstract Hilbert spaces. These are complex linear spaces on which there is defined an inner product $\langle x, y\rangle$ with certain simple properties; the norm is $\|x\| = \langle x, x\rangle^{1/2}$, and the space is complete in this norm. A linear operator L defined on a dense subset D of the space is self-adjoint if for each y in the space, $\langle Lx, y\rangle$ is bounded for all unit vectors x in D if and only if y is in D, and then $\langle Lx, y\rangle = \langle x, Ly\rangle$. For such operators he developed a spectral theory. Now both the sequences used by Heisenberg and the functions used by Schrödinger were elements of Hilbert spaces, and Heisenberg's transformations by matrices and Schrödinger's transformations by differential operators were corresponding self-adjoint linear operators. So the two theories were two concrete realizations of one abstract theory. This did not merely resolve the apparent conflict. It also gave a sound foundation for further advances in quantum theory. On the other hand, it also opened a field for pure mathematical research that has continued to prove fertile ever since.

Although this application of abstract Hilbert space theory in quantum mechanics is of great importance, for the purposes of this talk it has a serious defect. Either a listener will know quantum theory, in which case I should merely have used a few words to remind him of what he knows; or else he does not know quantum theory, in which case I am asking him to take quite a bit on faith. So it is worth while to look at another example, in which the abstract

structural study and the concrete uses are both easily visible, and in which the basic ideas can be explained in a few minutes. This is the Mikusiński operational calculus.

4. Operational calculus. In the 1890's Oliver Heaviside was busily solving differential equations by replacing the operation of differentiation by the letter D and then optimistically acting as though D behaved in all respects like a real number. His objects were to solve the equations and to infuriate the mathematicians, and he did both. Much later, it was found that most of the differential equations solvable by Heaviside's methods could also be solved by use of the Laplace transform. However, this presupposed a knowledge of the theory of the Laplace transform, and restricted the operational calculus to those functions possessing transforms.

Important in the Laplace transform theory is the convolution. For brevity we shall understand that all functions mentioned are defined and real-valued on $(-\infty, \infty)$ and vanish on $(-\infty, 0)$, and are Lebesgue integrable over every interval $[a, b]$. The convolution $f*g$ of two such functions is that function whose value at x is

$$\int_{-\infty}^{\infty} f(x-t)g(t)\,dt.$$

This operation is commutative and associative. In 1924 Titchmarsh proved an easily stated but deep theorem about convolutions. If $f*g$ is almost everywhere 0, then either f is almost everywhere 0 or else g is.

Now let us remember how we can construct the rational numbers from the integers, by defining them to be equivalence-classes of ordered pairs of integers. We can duplicate this faithfully using convolution in place of multiplication. We define two ordered pairs (a, b), (f, g) of functions to be equivalent if $a*g=b*f$. This relation is reflexive and symmetric; by Titchmarsh's theorem, it is also transitive. It therefore classifies all ordered pairs of functions into equivalence classes, which we call operators. If we define multiplication and addition as though the pairs were fractions, we obtain the usual laws. In particular, to each function f corresponds an operator $f\dagger$ consisting of the pairs $(a*f, a)$ for all non-zero a; and we verify at once

$$(f*g)\dagger = f\dagger \cdot g\dagger,\ (f+g)\dagger = f\dagger + g\dagger,\ (cf)\dagger = cf\dagger$$

(c real). But there are operators other than these. For the class of pairs (a, a) is the identity for multiplication, and there is no function δ for which $f\dagger \cdot \delta\dagger = f\dagger$ for all f. Engineers and physicists have for years been making profitable use of this non-existent function; it is commonly called the "Dirac δ-function," and it is described neatly and nonsensically as the function which vanishes everywhere except at $x=0$, and is there so very infinite that its integral is 1. Ignoring the fact that this is impossible, we find that $f(x-t)\delta(t) = f(x)\delta(t)$ for all t, since it is

obviously true if $t=0$, and both have the factor $\delta(t)=0$ otherwise. Hence

$$[f*\delta](x) = \int_{-\infty}^{\infty} f(x-t)\delta(t)\,dt$$

$$= \int_{-\infty}^{\infty} f(x)\delta(t)\,dt$$

$$= f(x).$$

Hence $f\dagger\cdot\delta\dagger=f\dagger$, and $\delta\dagger$ is the identity in operator space. Now there is no function δ on $(-\infty, \infty)$ with the properties wished for; but in operator space there is an operator, the identity, which will truly and rigorously possess the properties that we would find in the operator corresponding to the wished-for "δ-function." Thus the success of the engineers in using the δ-function is explained. If we map all our functions into operator space and carry out our computations in that space, ending up with operators that are images of functions, it is quite possible that in the intermediate steps we may have used operators which are not images of functions. If we now re-write our work as though it were in function space, in place of these operators we have to insert symbols such as δ, δ', etc., that are not really names of functions. Nevertheless, the final result is sound because we have merely written a notational caricature of a logically sound operational calculation.

If h is the Heaviside function, that is $h(x)$ is 0 or 1 according as $x<0$ or $x\geqq 0$, and if for a function f of the type under consideration we define

$$F(x) = \int_0^x f(t)\,dt,$$

then $h*f=F$. Hence $h\dagger\cdot f\dagger=F\dagger$; the operation of indefinite integration among functions corresponds to multiplication by $h\dagger$ among operators. But every operator (a, b) with a and b not almost everywhere 0 has a reciprocal (b, a). In particular, $h\dagger$ has a reciprocal; let us call it s. (It is *not* the $\dagger$-image of a function.) Now we know that this operator s behaves among operators the way Heaviside presumed that D behaved wherever he wanted it to, and the long-used operational treatment of linear differential equations with constant coefficients is on a firm basis.

The theory we have just sketched exhibits several of the properties of abstract structural analysis at its best. It eliminates analytic machinery that had been inescapable in former treatments; it does not merely postpone the tedious part, leaving it to be done each time that we wish to apply the general theory to some specific situation. It does not attain a spurious generality by omitting the "nonessential" or "uninteresting" parts of the more special theories (these are by definition the parts that the generalization fails to cover); in fact, it covers much more territory than the Laplace transform did, and no one knows what

Heaviside may have thought he covered. It does not lose contact with the uses for which the original theory was devised; in fact, Mikusiński's book is full of applications to such things as electric circuits.

It is evident that a common generalization of several mathematical statements cannot contain every detail of each instance—if it did, we could not distinguish it from the instances. A good generalization has a satisfying extensiveness while retaining the good flavor of the interesting instances—and this is a highly subjective criterion. Clearly present-day taste runs much more to a liking for wide coverage and much less to a liking for individual charm than did that of earlier times. Sometimes it has been realized that the process of generalization discarded properties that were too valuable to ignore, and then a different generalization was developed to recover what had been bypassed. Thus in treating aggregates of functions as linear spaces we ignored the fact that functions can be combined otherwise than by linear combination, for instance by multiplication or convolution. So along with Banach spaces we now study Banach algebras. Again, in extending Fourier theory to abstract harmonic analysis one ignored the possibility of extending Fourier series and transforms from the real axis to the complex plane. But now the Fourier series in the complex domain are back as subjects of active study. However, at the present rate of proliferation of mathematics the only alternative to inundation is a process of coalescence, by which the mass of accumulated information is molded into coherent general schemes. Probably in the process we lose many details that ought to have been kept, whatever that means. But as gain we have a structure whose beauty often repays the loss of the decorative individual peculiarities—and survival is a gain too.

5. Theory of Distributions. The theory of distributions, or generalized functions, which is pervading more and more of analysis, is one which, even if it had been invented, could hardly have attained wide acceptance except in a mathematical community already imbued with the concepts of linear topological spaces. We have already seen how the "Dirac δ-function" and its derivatives can be made intelligible and safely usable by first mapping functions into the space of Mikusiński operators and then noticing that other well-defined operators behave the way that the correspondents of δ, δ', etc. should. The method of Sobolev and of Schwartz involves a different imaging of the ordinary functions. To make it easy, we consider real functions f of one real variable that are Lebesgue integrable over every interval. Let $\mathfrak{D}$ denote the class of all infinitely differentiable functions that vanish outside some interval. For each function ϕ in $\mathfrak{D}$ there is a number

$$f\dagger(\phi) = \int_{-\infty}^{\infty} f(t)\phi(t)\,dt,$$

so $f\dagger$ is a function on $\mathfrak{D}$. It is clearly linear. If we define a very stringent limit concept in $\mathfrak{D}$ by saying that $\phi_n \to \phi$ if and only if there is an interval outside of

which all the ϕ_n vanish, and $\phi_n(x) \to \phi(x)$ and $d^m\phi_n(x)/dx^m \to d^m\phi(x)/dx^m$ for all x and all positive integers m, then $f\dagger$ is continuous; if $\phi_n \to \phi$, then $f\dagger(\phi_n) \to f\dagger(\phi)$. Moreover, two functions f_1, f_2 that differ on a set of positive measure will have $f_1(\phi) \neq f_2(\phi)$ for some ϕ, so that f is uniquely determined by $f\dagger$, up to sets of measure 0. But there are far more continuous linear functions on $\mathfrak{D}$ than those of the type $f\dagger$ just discussed. These, all together, are the "distributions," or "generalized functions." For instance, if there were such a function as the δ-function, we would have

$$\delta\dagger(\phi) = \int_{-\infty}^{\infty} \delta(t)\phi(t)\, dt = \phi(0)$$

for all ϕ in $\mathfrak{D}$. Now $(\phi(0) : \phi \in \mathfrak{D})$ is a perfectly good linear continuous functional on $\mathfrak{D}$; it is a distribution, and can perfectly well be called the δ-distribution. The preceding equation is, properly speaking, nonsense, since it involves the "δ-function" $\delta(t)$. Nevertheless, either in recognition of the convenience to physicists of pretending that such a function exists, or else in the spirit of "if you can't lick 'em, jine 'em," mathematicians are now quite willing to speak of δ-functions and to write them in integrands whenever convenient. After all, neither in mathematics nor out of it is there any harm in using intrinsically nonsensical expressions, provided that the listener knows what is nonsensical about them and can be trusted to replace them by what we really mean to say.

If f is absolutely continuous, the distribution corresponding to f' has value at ϕ

$$f'\dagger(\phi) = \int f'(t)\phi(t)\, dt = \int f(t)[-\phi'(t)]\, dt = f\dagger(-\phi').$$

Accordingly, for any distribution F we define the distributional derivative DF by $DF(\phi) = F(-\phi')$. Now all distributions are differentiable, hence infinitely differentiable. However, we must remember that in general $Df\dagger$ is not the distribution corresponding to f'. For example, for the Heaviside function h we have $h'(t) = 0$ except at $t = 0$, hence $(h')\dagger = 0$; but

$$h\dagger(\phi) = \int_{-\infty}^{\infty} h(t)\phi(t)\, dt = \int_{0}^{\infty} \phi(t)\, dt$$

so

$$Dh\dagger(\phi) = \int_{0}^{\infty} [-\phi'(t)]\, dt = \phi(0),$$

and thus $Dh\dagger$ is the δ-distribution. More generally, if f is of bounded variation on every interval, the value of the distributional derivative $Df\dagger$ at the test-function ϕ is

$$\int_{-\infty}^{\infty} \phi(t)\, df(t),$$

which is not in general the same as the integral of $\phi f'$.

The usefulness of distributions was their birthright, since their invention was motivated by the insistence of physicists and engineers that δ-functions were too useful to abandon merely because they were meaningless. Now more and more mathematicians are becoming comfortable in their presence, and are using δ-functions and other distributions in their everyday thinking and in their published papers, and they are finding these objects as convenient as did the engineers. There is a whole theory of Fourier series and Fourier transforms of distributions, more or less paralleling the classical theory, going far beyond it in some directions, but necessarily paying the price of not giving all the wealth of known detail that abounds in the older theory. (A theory in which everything is differentiable can hardly draw subtle distinctions based on continuity and differentiability properties.)

6. Differential Equations. Another field in which distribution theory plays a large and increasing rôle is differential equations. It would probably be wrong to say that one of the trends in analysis is toward the study of differential equations. I do not know of any time since the beginnings of analysis at which differential equations were not among the objects of major attention of analysts. If there is a trend to note in this connection, it might be a trend to assimilate all relevant advances in mathematics and use them to increase our knowledge of differential equations. This has of course been done with distributions. Even if these gave no new results, they would be helpful in clarifying our ways of thinking about differential equations, making the essential and crucial ideas stand out more clearly from the analytical machinery. When we say, for example, that the Green's function $g(x, t)$ of a differential operator L (in one variable) is the solution of $Lg = \delta(x-t)$, we have not only given a compact definition, we have almost given directions what to do with it.

Once again, let me say that this incorporation of new constructions is by no means the only activity in differential equations. One of the most novel results of recent years is contained in a short paper by Hans Lewy. If $F(x_1, x_2, y_1)$ is any reasonably well behaved function of three variables and c_1, c_2, c_3 are complex numbers not all 0, it is known that there exists a complex valued function $u(x_1, x_2, y_1)$ that satisfies

$$c_1 \partial u/\partial x_1 + c_2 \partial u/\partial x_2 + c_3 \partial u/\partial y_1 = F(x_1, x_2, y_1).$$

It was reasonable to conjecture that if the c_j were replaced by well-behaved functions of x_1, x_2 and y_1, the solution should still exist. Lewy proved the unexpected theorem that with $c_1 = 1$, $c_2 = i$, $c_3 = 2x_2 - 2ix_1$ there is an infinitely differentiable function F for which the equation has no solution with Hölder-con-

tinuous derivatives, not even on any neighborhood of any point. This has led to considerable further study. Hörmander has found conditions on the coefficient functions that determine whether or not the equation is of the solvable kind or not (and also got rid of the Hölder continuity); and we now know a good bit more than before about solvability of partial differential equations. But it remains true that this growth has its roots in one highly instructive and concrete example.

Before going on to the next topic, I want to talk for a moment like a physicist. Suppose that $f(x, t)$ $(-\infty < x < \infty,\ 0 \leqq t < \infty)$ represents the temperature at place x and time t in an infinitely long uniform rod. By the elementary physics of heat conduction, if f is a sufficiently well-behaved function it should satisfy the differential equation

$$\frac{\partial f}{\partial t} = k\frac{\partial^2 f}{\partial x^2}, \tag{1}$$

where k is a constant whose value depends on the structure of the rod. Subject to the condition that the initial temperature distribution $f(x, 0)$ is a twice-differentiable function $g(x)$ that does not increase faster than exponentially, we can solve this easily and find

$$f(x, t) = \frac{1}{2k\sqrt{2\pi t}} \int_{-\infty}^{\infty} \exp\left[-(\xi - x)^2/4k^2t\right] g(\xi)\, d\xi. \tag{2}$$

But what the physicist really wants is not to solve the differential equation, for this is just a mathematical device to help in analyzing the physical situation. What he is looking for is the temperature distribution $f(x, t)$ that results t seconds after an initial distribution $g(x)$. The right side of the preceding equation defines a transformation of g into $f(x, t)$; we can call this T_t, and condense the equation to $f(x, t) = [T_t g](x)$.

From the physics of the problem it is clear that if we start with distribution g and wait t seconds, and then start again with the resulting distribution $T_t g$ and wait s more seconds, the resulting distribution $T_s[T_t g]$ is the same as the result $T_{s+t}g$ of starting with distribution g and waiting $s+t$ seconds. At this point it is tempting to use an argument of a type of which physicists are occasionally guilty: because our solution is the mathematical model of a physical process in which we evidently have $T_s T_t = T_{s+t}$, our expression for T_t (deduced from the differential equations) must have this property. As cautious mathematicians, all we can say is that either the transformation defined by our integral formula satisfies $T_s T_t = T_{s+t}$ for all non-negative s and t, or else our mathematical model fails to match the physics. The equation $T_s T_t = T_{s+t}$ must be verified from the mathematics, not from a physical analogy. Fortunately the verification is not difficult; we readily show that if g is continuous and does not increase faster than exponentially, the same is true of $T_t g$, and $T_s T_t g = T_{s+t} g$ for $s, t \geqq 0$. That is, the

$T_t (t \geqq 0)$ constitute a *one-parameter semi-group* of linear transformations on a function-space.

If we would permit ourselves the luxury of the most unexamined use of formal procedures, from the identity

$$h^{-1}(T_{t+h} - T_t) = [(T_h - T_0)/h]T_t$$

we would deduce $T_t' = T_0' T_t$, and by iteration $T_t^{(n)} = [T_0']^n T_t$. Recalling that T_0 is the identity, the value of $T_t^{(n)}$ at $t=0$ is $(T_0')^n$, and if we expand in a Maclaurin series

$$T_t = \sum_0^\infty [(T_0')^n/n!]t^n = \exp(tT_0').$$

Thus T_0' determines T_t for all t; it is the "infinitesimal generator" of the semi-group. This is pure formalism. Nevertheless, given the semi-group defined by (2), we find that if g has a continuous second derivative that increases at most exponentially with $|x|$, then

$$\frac{d}{dt} T_t g \Big|_{t=0} = kg''. \tag{3}$$

[The calculation uses the fact that the second partial derivatives of

$$\exp[-(\xi - x)^2/4k^2t]$$

with respect to x and with respect to ξ are equal, and involves two integrations by parts.] So the infinitesimal generator of our particular example of semi-group is the operation $k\partial^2/\partial x^2$, and (3) is the same as (1) at $t=0$. This indicates that there is an intimate mutual relationship between one-parameter semi-groups and differential equations of the form

$$\frac{\partial f}{\partial t} = Af,$$

where A is a differential operator, namely the infinitesimal generator of the semi-group. There has been a good deal of significant research on the properties of semi-groups and their infinitesimal generators. More relevant to the purpose of this talk is the observation that the concept of semi-group has become very widespread. The defining property of a semi-group is so simple, and the kind of heuristic argument by which we were led to it can be applied to so many situations both in pure mathematics and in applications, that it is not surprising that examples are abundant. Now, when one meets such an example, he is ready to observe the fact, and thereby to increase his grasp of the mathematical object.

7. Probability Theory. When I was an undergraduate, the standard freshman course in mathematics included a small amount of probability theory, confined

to the simplest problems concerning random variables that could take on only finitely many values. But I believe that most mathematicians then regarded probability theory as at best dubiously respectable. Quite unrelated to this, the concept of Lebesgue measure had been widened to apply in spaces other than finite-dimensional; this extension was one of the evidences of the power of the ideas used, but seemed of rather esoteric interest only. In 1906, Einstein published his famous study of the Brownian motion. If a fluid contains a large number of similar microscopic particles, it can be regarded as a mixture of two fluids, the second consisting of huge "molecules," i.e. the particles. If the statistical mechanical theory of diffusion is correct, these particles should have random motions such that, if $x(t)$ is the x-coordinate of a particle at time t, the displacement $x(t_2)-x(t_1)$ during a time interval $[t_1, t_2]$ should be independent of the history of the particle before time t_1, and should be a normally distributed random variable with variance proportional to t_2-t_1; that is, the probability of being in a set A at time t_2 is

$$\frac{1}{k\sqrt{2\pi(t_2 - t_1)}} \int_A \exp\left[-(y - x(t_1))^2/2k^2(t_2 - t_1)\right] dy, \tag{4}$$

where the proportionality constant k involves the diffusion coefficient of the fluid. Einstein thus found striking evidence for the validity of statistical mechanics. Moreover, given times $0<t_1<t_2< \cdots <t_n$ and intervals $[a_1, b_1]$, $\cdots$, $[a_n, b_n]$, it is easy to calculate the probability that a particle starting at $x(0)=0$ will have $x(t_j)$ in $[a_j, b_j]$ for $j=1, \cdots, n$. That is, we have assigned a numerical probability to the event that a Brownian-motion path belongs to the set of paths satisfying

$$a_j \leqq x(t_j) \leqq b_j \qquad (j = 1, \cdots, n). \tag{5}$$

In 1923 Norbert Wiener combined these assorted ideas into a powerful unit. The set of all real-valued functions on $[0, \infty)$ is a linear space. The sets (5) and their finite unions form a small but important family of subsets of this space, and on them we have a finitely-additive measure defined, namely their probability measure. Wiener showed that this measure can be extended to be defined and countably additive on a σ-algebra of subsets of the function space. Moreover, this can be done in such a way that the set of all discontinuous functions (although of a higher order of infinity than the set of continuous functions) has measure zero. This immediately made all the powerful machinery of the Lebesgue integration theory available for studying probability theory in this function space. Moreover, it served as a point of entry into the theory of random functions.

To give a quick glance at the relationship of this theory with other parts of analysis, we shall ignore all the inescapable and sometimes difficult questions of measurability, integrability, etc., and consider a set of probability measures $p(t, x, A)$, where $t \geqq 0$, x is in Euclidean n-space, and A is a Borel set in n-space.

We suppose that for fixed t and x, $p(t, x, A)$ is a probability measure defined for Borel sets; it is to be interpreted as the probability that a particle starting at place x at an arbitrary time t_0 shall be located in set A at time t_0+t. This is supposed to be independent both of the time t_0 and of what happened to the particle at times before t_0. Then, speaking somewhat sloppily, the probability that the particle, starting at time t_0 at place x, will at time t_0+t be in a tiny cube dy containing a point y, and at time t_0+t+s will be in A, is the product of the probability $p(t, x, dy)$ that it gets into dy at time t_0+t and the probability $p(s, y, A)$ that s seconds later it gets from there to A. If it is in A at time t_0+t+s, it had to be at some place y at time t_0+t, so by integrating with respect to y we find

$$p(t+s, x, A) = \int p(t, x, dy)p(s, y, A). \tag{6}$$

This is the Chapman-Kolmogorov equation. Now for all functions g in some class of functions on n-space (including surely all bounded Baire functions) the integral

$$\int g(y)p(t, x, dy) \tag{7}$$

is defined for each x in the space, and is therefore a function on the space, which we call $T_t g$. It is evident that T_t is a linear operation, and by the use of the Chapman-Kolmogorov equation we can easily show that $T_s T_t = T_{s+t}$, so the T_t form a one-parameter semi-group of transformations on a function space. But we have already seen that the semi-group is closely related to the equation

$$\frac{\partial}{\partial t} f(x, t) = Af(x, t),$$

where A is the infinitesimal generator of the semi-group and is often expressible as a differential operator involving the partial derivatives of f with respect to $x_1, \cdots, x_n$. To give a specific example, let the transition probabilities be those assumed by Einstein in his study of the Brownian motion (see (4)). If we substitute this in the definition (7) of $T_t g$, we obtain exactly the right member of equation (2). So the transformation semi-group T_t ($t \geqq 0$) of the Brownian motion is the same as the semi-group associated with the heat equation (1), which in the present setting should be renamed the diffusion equation. Since the Brownian motion is merely one of many Markov processes, equation (1) is merely one of many differential equations related to stochastic processes. If a mathematician is interested in any one of the three theories (differential equations, semi-groups, stochastic processes), the more he knows of the other two the better off he is.

To show the connection of stochastic processes with other types of differential equations, let us consider the Dirichlet problem; given a bounded open set B (say in the plane) and a reasonably well-behaved function g on its boundary ∂B, we wish to find a function harmonic on B, continuous on $B \cup \partial B$, and agreeing

with g on ∂B. Let x be in B and let A be a Borel subset of ∂B. (The letters x, y, z will stand for vectors in the plane, $x=(x_1, x_2)$, etc.) If a particle begins Brownian motion at x, with probability 1 it will follow a continuous path that at some time leaves B. We denote by $p(x, A)$ the probability that the first point on its path that is out of B (which surely is in ∂B) will be a point of A. This is a probability measure on the Borel subsets of ∂B, and by integration we can define a function

$$f(x) = \int_{\partial B} g(y)p(x, dy). \tag{8}$$

It is not hard to give an indication of proof that as $x \to y$ ($x \in \partial B$, $y \in B$) we have $f(x) \to g(y)$, at least where ∂B is not too complicated. To indicate that f is harmonic we by-pass all proofs of measurability, although they are both essential and difficult, and argue thus. Let S be a circle centered at x and contained, with its interior, in B. We denote by $z(\vartheta)$ the point of S such that the vector from x to $z(\vartheta)$ makes angle ϑ with the positive x_1-axis. With probability 1 the moving particle leaves the interior of S; and by the rotational symmetry of the quantities involved, the probability that the first point at which it meets S will be in an arc A_0 subtending an angle $\triangle\vartheta$ is proportional to $\triangle\vartheta$. Since this must be 1 if A_0 is S, the probability is $\triangle\vartheta/2\pi$. Now if A is a Borel subset of ∂B and A_0 is a very short arc containing a point $z(\vartheta)$, it is clearly a reasonable conjecture that the probability that the particle will first hit S in A_0 and then go on to hit A before hitting any other point of ∂B is very nearly $[\triangle\vartheta/2\pi]\cdot p(z(\vartheta), A)$. But to hit A it must go through some point of S, so if we integrate this expression over all of S we get the probability that it will first hit ∂B in a point of A:

$$p(x, A) = \frac{1}{2\pi}\int_S p(z(\vartheta), A)\, d\vartheta.$$

Substituting this in (8) yields

$$\begin{aligned} f(x) &= \frac{1}{2\pi}\int_S \int_{\partial B} g(y)p(z(\vartheta), dy)\, d\vartheta \\ &= \frac{1}{2\pi}\int_S f(z(\vartheta))\, d\vartheta. \end{aligned}$$

That is, the value of f at x is the mean of its values over the circle S with center x, and this characterizes f as a harmonic function.

Anyone speaking on the subject of stochastic processes here in Ithaca would be sadly remiss if he did not mention that outstandingly important contributions to this theory have been made by mathematicians associated either now or previously with Cornell University.

It is clear that activity in probability theory is waxing. This may quite possibly have an important side-effect. The geometrization of analysis influenced the direction of research by directing mathematicians' minds towards theorems

in analysis that are analogues of geometric statements that spring readily to mind, because of our life-long familiarity with geometry. Probability theory provides an additional source of images and analogies. One can hardly expect that the heuristic substitution of a "chance happening" model for an analytic statement will ever be quite as self-suggesting as the substitution of a "geometric figure" model, since we are unlikely ever to feel quite as informally at ease with chance events as with geometric diagrams. Nevertheless, to those who acquire some degree of relaxedness with probability, it may be an important auxiliary in conjecturing theorems and proofs.

8. Prophecy. I will finish off by allowing myself the luxury of two prophetical remarks, with full confidence that if my predictions are wrong no one will remember them anyhow. First, my old love, the calculus of variations, although rather thoroughly neglected for some years, is beginning to show signs of starting a new kind of development. Several recent research papers have been devoted to studying the minima of functionals involving random elements or integrals over function spaces. These are at present isolated results, not part of a coherent theory. But in view of the present interest in analyzing the abstract structures of mathematical theories, it would be quite natural to have these concrete examples embedded in a new and interesting kind of calculus of variations.

Second, the rapid growth of computing may well have a long-range effect on the direction of mathematical thinking. I do not mean that hordes of mathematicians will become computers or rush to put problems on the machines. However, in the process of developing those completely novel uses of computers that surely lie in our future, new methods of analyzing complicated situations will be called for, and when developed will be new parts of mathematics. When they become familiar, they will provide a new collection of familiar situations from which new abstract structures will be developed. But it is just as hopeless to predict the nature of these new structures by an extrapolation from today's numerical techniques as it would have been to predict the contents of Banach's "Théorie des opérations linéaires" by an extrapolation from plane geometry.

THE CLASSICAL GROUPS AS A SOURCE OF ALGEBRAIC PROBLEMS

C. W. CURTIS, University of Oregon

Introduction. Rather than attempting a general survey of what has been accomplished in algebra, I shall try to describe the influence on the development of algebra of one of the great sources of algebraic problems and ideas—the classical linear groups. I intend to show that these groups have provided an experimental, empirical basis for large parts of algebra. They are a family of examples which serve as raw material from which problems, conjectures, abstract ideas and general theorems have emerged, and which have provided direction and continuity to the research based on them. Surveys of recent developments and problems of current interest have been given by Brauer [5], [6], Carter [11], Dieudonné [24], M. Hall [26], Kaplansky [35], and MacLane [36].

It is impossible in this lecture to give an account of all the major results which involve the classical groups. In making a selection, I have simply included the material that has been most helpful to me.

1. Definitions and background. The story begins with Galois, who proved that a polynomial equation was solvable by radicals if and only if a certain finite group of automorphisms of a field was solvable. Thus he raised the problem of investigating groups in terms of their structure, and observed, as an example, that the set of all 2 by 2 invertible matrices with coefficients in a finite field of more than 3 elements, was a finite group that was not solvable.

Let us first give an up-to-date version of Galois' example. Let K be an arbitrary field, and V a finite dimensional vector space over K. The set of all linear transformations T of V which possess multiplicative inverses (and which we shall call invertible transformations) forms a group with respect to multiplication, called the general linear group $GL(V)$ of V. Hermann Weyl invented the term *the classical groups* to stand for $GL(V)$ and certain subgroups of $GL(V)$, which include the following ones.

(a) $SL(V)$, the unimodular group, consisting of all invertible transformations of determinant one.

(b) $O(V, f)$, the orthogonal group of a non-degenerate symmetric bilinear form f on V, consisting of all invertible transformations T that leave f invariant:

$$f(Tx, Ty) = f(x, y),\ x, y \in V.$$

For example, if V is n-dimensional euclidean space and $f(x, y)$ the usual inner product, $O(V, f)$ is the familiar group of linear transformations T that preserve lengths: $\|Tx\| = \|x\|$, where $\|x\| = f(x, x)^{1/2}$.

(c) $Sp(V, F)$, the symplectic group, consisting of all invertible transformations leaving invariant a non-degenerate skew-symmetric ($F(x, y) = -F(y, x)$) bilinear form F on V.

In order to understand why the list of classical groups does not continue, we have to return to Galois' observation about the structure of the classical groups.

Suppose we have, more generally, a family of algebraic systems $\{G_\alpha\}$ for which the fundamental theorem of homomorphisms is valid, such as groups, rings, algebras, etc. Whenever we have a homomorphism

$$\phi: G \xrightarrow[\text{onto}]{} H$$

with kernel L, G is called an extension of H with kernel L. G is called *simple* if whenever G is an extension of H with kernel L, then either G is isomorphic to H, or G is isomorphic to L. Given a family $\{G_\alpha\}$ of simple systems, the *extension problem* asks for the construction of all systems G for which there is a sequence of homomorphisms

$$\phi_1: G \xrightarrow[\text{onto}]{} G_{\alpha_1} \in \{G_\alpha\}$$

with kernel G_1,

$$\phi_2: G_1 \xrightarrow[\text{onto}]{} G_{\alpha_2} \in \{G_\alpha\}$$

with kernel G_2, etc., and such that for some k, the kernel G_k belongs to the family $\{G_\alpha\}$. The systems G determined in this way are built up from the simple systems $\{G_\alpha\}$ by solving the extension problem.

Solvable groups are the result of applying this process to the family $\{G_\alpha\}$ of cyclic groups of prime order. Galois' observation that the classical groups are not solvable shows that the classical groups are built up from non-abelian simple groups by solutions of the extension problem.

The problem of which simple groups are derived from the classical groups was investigated first by Jordan and Dickson ([34], [21]) with Dickson's book in 1901 containing fairly complete results for the classical groups defined over finite fields. Dickson's proofs, while satisfactory at the time, involved exhausting calculations with matrices which are a tribute to his persistence, but often left obscure the essential ideas. The subject was taken up again by Dieudonné and Artin ([22], [23], [3]) who identified the simple groups derived from the classical groups over arbitrary fields by elegant methods using the geometric properties of linear transformations and subspaces of the underlying vector space.

The result of their investigations, which extended and clarified Dickson's work, can be summarized as follows. First of all consider all homomorphisms f_α of a group G onto abelian groups A_α with kernels G_α. It turns out that there is a unique minimal such kernel G' called the *commutator group* of G, which is generated by all commutators $(x, y) = xyx^{-1}y^{-1}, x, y, \in G$. Thus an arbitrary group is an extension of an abelian group with kernel equal to the commutator group. The first step in investigating the structure of classical groups was to find the commutator groups. In the case of $GL(V)$ the multiplication theorem for determinants gives a homomorphism of $GL(V)$ onto the abelian multiplicative group

of the field. With one exception (when V is the two dimensional space over the field of two elements), the commutator group turns out simply to be the kernel of the determinant homomorphism, $SL(V)$. The symplectic group is its own commutator group. The commutator group of the orthogonal group is more complicated. When isotropic vectors $v \neq 0$ such that $f(v, v) = 0$ are present, the commutator group of the orthogonal group is the kernel of a homomorphism called the spinor norm, whose construction depends on a certain associative algebra called the Clifford algebra of the form f, (see [23], [3]).

The main structure theorem on the classical groups, proved in special cases by Dickson, and in full generality by Dieudonné, is that, with a manageable number of exceptions, the commutator group G' of a classical group G is an extension of a non-abelian simple group with kernel Center(G'). In other words G'/Center(G') is a simple group, in most cases.

Dickson accumulated many other facts about the classical groups that proved to be useful for experimental purposes: he found the orders of the finite simple groups he had obtained, and partial information on their conjugacy classes and subgroups. All these results provided evidence that there should be general methods for studying these groups, without considering them one family at a time, as is the case in the approach both of Dickson and Dieudonné-Artin.

2. First attempts at a classification; Lie algebras. With the examples of simple groups furnished by the classical groups, and the alternating and Mathieu groups in the finite case, the problem arises to classify the non-abelian simple groups in some reasonable way, and in particular, to ask whether there are others. This problem, for arbitrary groups, still seems well beyond our reach, but is basic because the simple groups are the building blocks of arbitrary groups.

The first successful classification of simple algebraic systems which are relevant to our problem was contained in E. Cartan's thesis [9] in 1894, in which the simple Lie algebras over the field of complex numbers were classified. Since then Lie algebras have developed a life of their own (see [38], [32], [35]). The link between Cartan's work and group theory, however, can only be understood by plunging into the deep waters of Lie group theory, invented by Cartan's predecessor, Sophus Lie. For an up-to-date account of Lie group theory see Chevalley [13], Helgason [27], or Hochschild [29]. Thus the first successful classification of some kind of simple groups required heavy use of nonalgebraic methods, and shows that it may be shortsighted to expect a problem stated in algebraic terms to have a purely algebraic solution.

Without giving details, a complex Lie group G is a group which is at the same time a complex analytic manifold, such that the group operations are given locally by analytic functions. The classical matrix groups, with the operation of matrix multiplication, are the prototypes of Lie groups. From the manifold structure, a Lie group G has a tangent space $\mathfrak{g}$ at the identity, which is a finite dimensional vector space over the complex numbers. It is possible to define on $\mathfrak{g}$

a bilinear multiplication $[X, Y]$, satisfying the axioms of a Lie algebra:

$$[XX] = 0, \qquad X \in \mathfrak{g}$$
$$[[XY]Z] + [[YZ]X] + [[ZX]Y] = 0, \; X, Y, Z \in \mathfrak{g}.$$

It can then be shown, by an interesting combination of algebraic and analytical reasoning, that the group multiplication in a certain neighborhood of the identity is completely determined by the multiplication in the Lie algebra. Simple Lie groups have simple Lie algebras (where the concept of a simple Lie algebra is defined by the general remarks on the extension problem in section 1). Then the purely algebraic problem of classifying the simple Lie algebras implies a local classification of simple Lie groups.

The classical groups over the field of complex numbers are Lie groups, and to the simple groups derived from the classical groups correspond simple Lie algebras. Cartan's great achievement was to prove, completing a program already begun by Killing, that besides the simple Lie algebras corresponding to the classical groups, there are only 5 additional simple ones, called the exceptional Lie algebras, of dimensions 14, 52, 78, 133, and 248. There is a simple Lie group belonging to each of the exceptional simple Lie algebras, and the actual construction of the exceptional algebras and groups, has been one of the most striking applications of the theory of alternative and Jordan algebras. (See e.g. [30], [31], [32], [16], [47].)

The importance of Cartan's classification is that questions about properties of simple Lie algebras and Lie groups can be answered by checking against each type of algebra (or group) in the classification. Many interesting general problems and conjectures have been made in this experimental way, and later general solutions, independent of the classification, have been found for those that survived the case-by-case examination.

One difficulty in studying Lie groups via Lie algebras is that different Lie groups can have the same Lie algebra, and although homomorphisms of Lie groups always generate homomorphisms of the Lie algebra, the reverse statement is not necessarily true. But the most fundamental criticism from the point of view of algebra is that the classical groups are defined for arbitrary fields, while the Lie group machinery works smoothly only for groups which are real or complex analytic manifolds.

3. Representation theory. The next milestone after E. Cartan's work was Hermann Weyl's series of papers in 1925–1926 [50] on the representation theory of simple Lie algebras and Lie groups.

There were two problems, partly suggested by physical applications, that motivated the work on the representations.

One arises from the observation that a classical group G on a vector space V admits a homomorphism into the general linear group of the space of tensors

$$V^{(m)} = V \otimes \cdots \otimes V, \; (m \text{ factors})$$

given by

$$A \to A \underbrace{\otimes \cdots \otimes}_{m} A = A^{(m)}.$$

The problem was to decompose the tensor space $V^{(m)}$ into minimal invariant subspaces relative to the set of transformations $A^{(m)}$, $A \in GL(V)$.

A second problem, also suggested by physics, was to split up the space of continuous functions on the 2-sphere into minimal invariant subspaces relative to the action of the rotation group in 3-dimensional space.

These problems are both special cases of the following general problem. A group G is said to have a representation on a vector space M over a field K if there is a homomorphism $T: G \to GL(M)$. A subspace N is called a G-subspace if $T(g)N \subset N$ for all $g \in G$. The representation on M is called *irreducible* if the only G-subspaces are the trivial subspace $\{0\}$ and the whole space M, and *completely reducible* if M is a direct sum of irreducible G-subspaces.

At the time of Weyl's papers, there was already an extensive theory of representations of finite groups, due mainly to Frobenius, Schur and Burnside. In particular it was known that every representation of a finite group in a field of characteristic zero was completely reducible. (See [20], p. 41. The bibliography of [20] contains references to the original papers on representations of finite groups.)

Weyl, completing work begun by Cartan, classified explicitly the irreducible representations of the simple Lie algebras over the complex field, and proved also the theorem of complete reducibility for representations of simple Lie algebras, by using integration over a compact group associated with the Lie algebra. The Lie group—Lie algebra correspondence then solves the corresponding problems for representations of Lie groups. The failure of homomorphisms of the Lie algebra to generate homomorphisms of the group is strikingly illustrated by the spin representation of the rotation group. In this case, a representation of the orthogonal Lie algebra gives rise to a representation of a two-sheeted covering group of the rotation group, which cannot be viewed as a representation of the rotation group itself ([7], [13], Chapter 2, Section XI).

Weyl's work led first to a purely algebraic proof of complete reducibility of representations of simple Lie algebras by van der Waerden and the physicist Casimir [12]. Then J. H. C. Whitehead gave a new and profoundly original proof of the theorem on complete reducibility ([52], [53]) that can be viewed as the beginning of the cohomology theory of Lie algebras, and contains the motivation for at least a chapter of homological algebra ([38], [10]).

In 1939, Weyl returned to the subject, and in his book on the classical groups [51], he gave a new determination of the irreducible tensor representations of the classical groups over fields of characteristic zero, using the Wedderburn structure theory of associative algebras in an ingenious manner due to Schur, Brauer and himself. This method avoided the Lie algebras and their accompanying

analysis, and gave one of the first solutions since Dickson's book of a deep problem involving the classical groups by purely algebraic methods.

Weyl's paper ([50] p. 358–359) also contained an explicit formula for the characters of the irreducible representations of the simple Lie groups, which has inspired other combinatorial investigations on the representations of Lie groups and Lie algebras by Freudenthal, Kostant, Steinberg and others (see [32], Chapter VIII, for a complete account). This work includes a generalization of the Clebsch-Gordan formula for splitting up the tensor product of two irreducible representations of the unimodular group on a two dimensional space, into irreducible components (see [49], pp. 127–131).

4. Algebraic groups. The key to the discovery of a uniform approach to the classical groups was contained in Weyl's 1925–26 papers, where he proved (see [50] pp. 338–342) that a simple Lie algebra over the complex numbers was determined up to isomorphism by a certain finite group of permutations of one-dimensional subspaces of the Lie algebra. Weyl proved that these groups were all isomorphic to finite groups generated by reflections in euclidean space E^n.

In 1934–35, Coxeter proved ([17], [18]) that a finite group was isomorphic to a group generated by reflections in E^n if and only if as an abstract group, it had generators $S_1, \cdots, S_n$ which satisfied the defining relations

$$S_i^2 = 1,\ 1 \leqq i \leqq n, \text{ and } (S_iS_j)^{n_{ij}} = 1,\ i \neq j.$$

He determined all such groups, and proved that the ones corresponding to simple Lie algebras were precisely those groups generated by reflections satisfying a certain crystallographic condition on the angles between the reflecting hyperplanes.

In 1941, Stiefel proved that the Weyl-Coxeter group of a Lie algebra could be constructed within a compact Lie group belonging to the Lie algebra [41]. Specifically, the Weyl-Coxeter group of G is isomorphic to $N(T)/T$ where T is a maximal torus in G, and $N(T)$ its normalizer. Using Lie theory, it followed that the structure of G was determined, at least locally, by the finite group $N(T)/T$.

The stage was now set for attempting to classify simple groups of Lie type over arbitrary fields, now that an internal key to their structure had been found. To replace the analytical machinery of Lie groups, algebraic geometry was used, since by that time the foundations of algebraic geometry over arbitrary ground fields had been laid by Zariski and Andre Weil.

Hermann Weyl had already observed ([51], p. 147) that the classical groups could be viewed as the intersection of an algebraic variety in the space $M_n(K)$ of all n by n matrices over K with the general linear matrix group $GL(n, K)$. Such a group is called an *algebraic group*, and again the prototypes are the classical groups. For example the unimodular group is defined by the polynomial relation

$$\det(X) - 1 = \sum \pm x_{i_1 1} x_{i_2 2} \cdots x_{i_n n} - 1 = 0.$$

In 1956–58, Chevalley succeeded in classifying all simple algebraic groups over algebraically closed fields of arbitrary characteristic [15]. He proved that such a group was determined up to isomorphism by a Weyl-Coxeter group exactly as in the case of compact Lie groups, and that the Weyl-Coxeter groups which appeared satisfied the crystallographic restriction. Since the groups with these Weyl-Coxeter groups were known, it followed that the only simple algebraic groups were the classical groups and the five types of exceptional groups. The proof of Chevalley's result makes heavy use of the techniques of algebraic geometry. It depends on some basic work of A. Borel on solvable algebraic groups.

5. Finite groups of Lie type. Until 1955 no simple finite groups were discovered that were not already known to Dickson. In his famous Tôhoku Journal paper [14] of 1955, Chevalley constructed a simple group associated with every simple Lie algebra over the complex field and every field K, with some exceptions when K is the field of 2 or 3 elements. His construction yielded finite simple groups corresponding to the exceptional Lie algebras, and gave a uniform method for investigating the groups, which is based on new structural properties of the groups.

Chevalley proved first that a simple Lie algebra $\mathfrak{g}$ over the complex numbers has a basis $X_1, \cdots, X_n$ such that

$$[X_iX_j] = \sum c_{ijk}X_k,$$

where the $\{c_{ijk}\}$ are integers. This multiplication table serves to define a Lie algebra $\mathfrak{g}_K$ over an arbitrary field K, since the structure constants $\{c_{ijk}\}$ can be viewed as elements of K. The Chevalley group G associated with the Lie algebra $\mathfrak{g}$ and the field K is defined to be a certain subgroup of the automorphism group of $\mathfrak{g}_K$. Chevalley then proved by a long argument, but one that broke with tradition by treating all the groups at once, that with a few exceptions, the groups G were all simple.

For a Lie algebra $\mathfrak{g}$ associated with one of the classical groups, the Chevalley group of $\mathfrak{g}$ and K coincides with the simple group derived from the corresponding classical group [37]. In case K is the complex field, the Chevalley groups over K yield a complete set of simple Lie groups with complex parameters. If K is algebraically closed, of arbitrary characteristic, then the Chevalley groups give a complete set of examples of simple algebraic groups defined over K, by the classification theorem for algebraic groups. If K is a finite field, then the Chevalley groups include the finite simple groups investigated by Dickson, Dieudonné and Artin, and those associated with the exceptional Lie algebras give infinite families of finite simple groups not isomorphic to those in Dickson's original list.

The proof of this last fact requires formulas for the orders of the Chevalley groups defined over finite fields. Chevalley [14] derived these formulas using some topological properties of the Lie group of the same type, and recently L. Solomon [40] has given another derivation of the formulas using some topo-

logical properties of the Weyl-Coxeter group of the Lie algebra. No purely algebraic derivation of the formulas is known. A knowledge of the formulas is important because of a number theoretical study by Artin ([1], [2]) of the orders of the known simple groups which, among other things, gives a method of showing that different Chevalley groups in general cannot be isomorphic.

6. Further results on finite groups. The excitement over Chevalley's paper had hardly died down before new infinite families of finite simple groups were discovered, by Hertzig, Ree, Steinberg, Suzuki, and Tits (see [11]). Some of these were defined by analogy with the classification of simple algebraic or Lie groups, where it was known that among the groups parametrized by fields which were not algebraically closed, certain twisted versions of the Chevalley groups could occur. All are obtained from a Chevalley group by the following sort of construction. Certain Chevalley groups G, defined for certain fields K, admit automorphisms of period 2 or 3 such that the set of elements in G left fixed under the automorphism contains a new simple group. Of course we do not know whether we have seen the last of these constructions, especially in view of a new simple group defined by Janko [33], of order $11(11+1)(11^3-1)$, which is a subgroup of a Chevalley group defined over the field of 11 elements, but is not obtained by the preceding general method.

Nevertheless the situation has crystallized enough for us at least to hope for uniform description of all the known finite simple non-abelian groups. For this we are indebted above all to J. Tits, whose work is still in the process of publication. From a close inspection of the construction of the Chevalley groups, Tits developed the following very simple but still rather mysterious set of axioms which are satisfied by all the known finite simple groups except possibly the Janko group, and are suggested by the structural properties of the groups derived in Chevalley's Tôhoku Journal paper. (See [44], [45], [46].)

A group G (not necessarily finite) is said to have a BN-pair if G is generated by subgroups B and N such that

$$B \cap N \text{ is a normal subgroup of } N; \text{ let } H = B \cap N.$$

$$N/H = \langle w_1, \cdots, w_n \rangle, \; w_i^2 = 1,$$

and for all cosets $w \in N/H$, and generators w_i of N/H,

$$w_i B w \subset BwB \cup Bw_iwB$$

and for each i

$$w_i B w_i \neq B.$$

The group $W = N/H$ is called the Weyl group of G, for the reason that the group N/H of an arbitrary finite group with a BN-pair is isomorphic to a group generated by reflections in euclidean space. Abstract groups with BN-pairs can be expressed as a union of (B, B) double cosets, $G = \bigcup_{n \in N} BnB$, with the double

cosets in 1–1 correspondence with the elements of the Weyl group, a decomposition discovered first for the classical groups by Bruhat [8]. All the Chevalley groups, as well as the twisted types, have BN-pairs. Among other things Tits has found an elegant proof of simplicity for certain types of groups with BN-pairs [46], that provides in almost all cases a much shorter and easier proof of simplicity of the Chevalley groups and the twisted types than the one given in Chevalley's paper.

It has also been possible, using the methods of Chevalley and Tits in combination with Lie algebra methods similar to those in Weyl's 1925–26 papers, to classify all the irreducible representations of the finite Chevalley groups and the twisted types, in an algebraically closed field of the same characteristic as the field by which the groups are parametrized, completing the work begun by Weyl for the classical groups over fields of characteristic zero ([42], [19]).

The complex representations and characters of the finite Chevalley groups have not yet been classified, partly because of our lack of knowledge about the conjugacy classes.

In this connection, the Jordan normal form theorem tells us that two elements X and Y of $GL(V)$ are conjugate, i.e., $X = ZYZ^{-1}$, if and only if they have the same Jordan normal form. The Bruhat decomposition $G = \cup BnB$ fails to give a normal form up to conjugacy for elements of a general Chevalley group. R. Steinberg [43] has recently given a normal form for certain conjugacy classes of elements in "simply connected" versions of all the Chevalley groups over algebraically closed fields, that includes the Jordan normal form as a special case. This powerful result has already had applications to the classification of algebraic groups over non-algebraically closed fields and may suggest a method of determining the conjugacy classes in finite Chevalley groups.

Behind all the fascinating special results and problems suggested by these developments, lies the austere and immensely difficult problem of classifying the finite simple groups. The classical groups on 2- and 3-dimensional spaces were determined in terms of the structure of their subgroups by Zassenhaus, Suzuki, and Brauer and his students. See Section 92 of [20] for a survey of this work up to 1962. Then came the great achievement for which the Cole prize in algebra was awarded at the Denver meeting of the American Mathematical Society last winter—Walter Feit and John Thompson's proof, published in 1963, of Burnside's conjecture that a non-abelian simple group must have even order [25]. Since then the pace in finite groups has picked up, with Thompson's proof that the only finite simple groups, all of whose proper subgroups are solvable, are the known ones, and related works of Suzuki and Gorenstein and Walter. This work brings together all that is known about finite groups because the inductive method of proof used in these questions presents one with a group whose structure is to be determined, given fairly complete information on the structure of its subgroups which may be solvable groups, p-groups, etc.

If we continue to believe, as of course we must, in the possibility of communicating mathematical proofs as well as statements of results, then we are faced with the difficult and important task of simplifying some of these Hercu-

lean arguments, which often run to two and three hundred pages, to the point where they can meaningfully be presented in lectures and text books.

A bright ray of light in this direction is Tits' classification of finite groups with BN-pairs. It was known for some time that in a BN-pair G whose Weyl group was the symmetric group S_3, a coset geometry could be defined that satisfied the axioms for a projective plane. D. G. Higman and McLaughlin [28] proved that if the group G was finite, the plane was Desarguesian, and that G was an extension of the simple classical group $PSL(3, K)$ for some finite field K. Tits has proved that there is a geometry associated with every finite group with a BN-pair, and has succeeded in classifying the possible geometries in most cases [45]. The difficulty in applying his work to arbitrary finite groups is that it seems to be very difficult to tell whether a group has a BN-pair or not.

7. Conclusion. There are many other important directions I have not been able to take up. One basic experimental fact we have observed is the strong dependence of the methods used for studying the simple groups and their representations on the field over which the groups are defined. To make precise and formalize this kind of dependence is one of the tasks of homological algebra. In this direction we have, for example, applications of Galois cohomology [39] to the study of algebraic groups defined over nonalgebraically closed fields, and important new constructions in the category of modules over a ring—the algebraic K-theory of Bass [4]—which are at least partly suggested by the study of linear groups over the ring.

I have been able, nevertheless, to tell enough of the story to show that the classical groups have successfully resisted the best efforts of three generations of mathematicians to subdue them, and continue to suggest interesting problems for further research. The methods that have been used represent strong improvements and refinements over those available to Jordan and Dickson and have found their way into our elementary teaching. Their continual interaction with other branches of mathematics, and physics, would have heartened Hermann Weyl, who expressed in the preface of his book [51] his concern over the dangers of a too thorough specialization of mathematical research. The permanent feature of all this work has been the source of the problems—the groups themselves.

I hope that what I have said makes it clear that in our capacity as teachers we should introduce our students to the empirical sources, the physical facts of our science, as well as to the general ideas and methods we use in our work.

Other sources of algebraic ideas that have had a similar influence are the theory of algebraic numbers, representations of finite groups, and algebraic geometry; but these I leave to another time and other speakers.

THE FUTURE ROLE OF THE FEDERAL GOVERNMENT IN MATHEMATICS

SAUNDERS MacLANE, University of Chicago

1. Preamble. Mr. Chairman, members of the Mathematical Association of America, and guests. At this meeting our Association comes to full maturity and wisdom, and this at a time when that wisdom is much needed to understand the rapid changes buffeting the mathematical world. First, a very minor example of these changes. A dozen years ago most of you wouldn't be here, and our chairman would be standing at the lectern reading my speech and trying not to let on where he disagreed with it. Today the government liberally supports travel to meetings—bringing you here to listen to my disembodied voice. Many examples, all more important than this one, show how the government support of mathematics has enormous effects on our science. However, there is no general agreement as to whether these effects are good, bad, or just indifferently expensive. Today I will try to describe some of the future effects, good or bad, as I see them. I expect that each of you will disagree with some of my conclusions and that some of you may disagree with all of them.

2. Present Situation. First, consider the present situation. Mathematics in the United States today is lively. Fundamental advances are being made. Famous hard problems have been solved. There is wide activity in many different mathematical specialties; applied mathematics is more vigorously developed than before. It is especially pleasant to contemplate this lively state of mathematics in our country, because this has not always been the case.

In the United States there is large scale government support of mathematics. This support on this scale is so new that many of our judgments are not adjusted to the situation. Let me give a personal example. A dozen years ago I was a department chairman, deciding about applications for government support; with my colleagues I tried to plan this support so that *nothing* vital would be lost if all government support suddenly disappeared—at that time such counsels of caution were common. Now they would be wholly unrealistic. Today there is no prospect that the government will *withdraw* its support (just because, if it did, many scientific activities would simply collapse). The problem is rather: What happens when the government *shifts* the direction of its support? The real problem before us is not the existence of government support of mathematics, but the wise *direction* of this support.

Here is a first controversial question. Is or is not the present lively state of mathematics in the United States the direct result of government support? The answer is not obvious. Indeed, I incline both to a *yes* and a *no*. "Yes," in the sense that the amount and volume of our mathematical activity would be impossible without government support. "No" in the sense that other important factors have been more vital stimuli to the quality of mathematics here. Ob-

serve that *all* the physical and *all* the biological sciences have partaken of government support. We must account somehow for the fact that mathematics is at present one of the healthiest of all these sciences. I hold that the health comes from certain internal sources of strength in mathematics. One source is the recent development of the habit of collaborative research. Twenty-five years ago a joint research paper was a rarity and, in most departments, seminars hardly existed. Today there is a lively flow of joint papers in nearly all fields of mathematics; these joint papers almost always represent an active sharing of ideas, quite different from the process present in some other sciences where the director likes to sign all papers which come from his laboratory. At the same time, every Department of Mathematics worth the name has a long weekly directory of research seminars; in each seminar a few people get together to discuss in detail what is going on in their specialty. I submit that this new habit of collaborative work has brought many American mathematicians to a much higher level of activity and development than would have been otherwise possible. I hold that the beneficial effects of these habits have been just as important as government support in developing the present lively state of mathematics.

3. The Future. This was a question of the past effects of government support. What about the future? Money directed toward mathematics may or may not be useful for the development of the science and may or may not be useful for other proper government purposes. It is very important to bear in mind that more money need not mean better science. I remind you of the Eilenberg proposal to ruin American mathematics in five years: Just give a five year leave of absence to all those research mathematicians able to direct Ph.D. theses. In the spirit of collaboration I offer the MacLane method of thwarting all proper government purposes: Offer to triple the salary of all those and only those mathematicians who work in *Categorical Algebra.* These fanciful examples I cite to emphasize the vital point: Money for mathematicians is not the main thing; it's how you spend it!

4. The mechanism of decision. What I now propose to do is to examine the mechanism of decision as to how the money is spent.

Decisions about the government support of science are fundamentally political decisions and not just scientific ones. Federal funds come from the taxing power of the government. The disbursement of these funds is, in the last analysis, made by decisions of the Congress, acting for what it judges to be the general welfare. Therefore, questions about government money for mathematics are political questions. In case you incline not to believe this, consider, please, the situation in physics. Recently a number of high energy physicists decided that a new and bigger accelerator was needed—perhaps up to 1000 billion electron volts. For this purpose, they prepared a pamphlet called "The Nature of Matter—Purposes of High Energy Physics," edited by Luke C. L. Yuan. This pamphlet, with articles by many able physicists, was not a scientific document but a propaganda document with scientific overtones. It set forth the political

reasons for spending the public monies not just on applied physics, but on physical studies aimed to discover basic facts about the structure of elementary particles. I believe this pamphlet has had the desired effect.

Now mathematics is surely not yet that expensive and consequently not yet that political, but on a smaller scale there is an exact parallel. In the long run, we must face the prospect that there will be documents entitled "The Nature of Mathematics—Purposes of High Abstraction," edited by Nicholas Bourbaki, and that these documents will be propaganda documents with scientific overtones. These documents should set forth the political reasons for spending the public monies not just on applications of mathematics, but on mathematical studies aimed to discover basic facts about the structure of abstract mathematical entities.

5. The establishment. Since decisions about federal funds for science are political decisions, it is most fortunate that this country has developed the practice of making these decisions with the help and the collaboration of scientists. The fact that so many scientists do take part in this decision process makes the process much more effective than it otherwise would be. In the course of this development there has grown up in Washington what I would like to call a "scientific establishment." Here I use the term "establishment" in the precise British sense. I might almost say that an establishment is a private club, complete with rules, memberships, and blackballs for outsiders, functioning in the public domain. In the United States this scientific establishment consists of many devoted scientists who work hard and travel far, all to no personal advantage, save that of possible influence on policies. The character of this establishment is much influenced by the wartime conditions of secrecy which conditioned its early years. By now the establishment has its own way of life, with frequent committee meetings and wordy and unanimous joint reports. The fact that these reports habitually express no minority opinions is in my view an anachronism arising from the early impression that such reports are science, where there can be agreement, and not politics, where there should be minority opinion.

It is a striking fact that mathematics is simply not a part of this scientific establishment. Let me expand this flat statement. If I define a mathematician to be one who has contributed to our science at least one idea, process, or theorem that others have used, then I know of exactly two mathematicians who are part of the establishment. Put differently, the scientific establishment shows the ratio of two mathematicians to sixty or more physicists and to fifty or sixty chemists.

This raises the question: Why is this so? This is a question full of fun, fascination, and controversy. There are many different explanations as to why mathematics does not belong to the establishment. One extreme view holds that other scientists deliberately keep the mathematicians out. A milder and more realistic version holds that the physicists and others just don't know many mathematicians and so don't happen to think of them when setting up committees. Still

another version (and I have seen real evidence for this version) is this: The scientific establishment was first forged during the Second World War under the fervor of work on important classified applied problems. When the groups to carry out this work were set up, about 1941, those who were responsible simply didn't know who the mathematicians were and even had sadly mistaken notions as to who the good mathematicians were. Still other reasons are offered. There is an extreme view that mathematicians almost always refuse to serve on committees; some part of this may be true; some mathematicians I have known very well are likely to be more critical than most scientists of the waste of time involved in committee meetings. A more modest version of this explanation holds that mathematicians have a sort of ingrown dislike for committees and administration. This may indeed have some basis in the nature of our science. In experimental science the facts found in the laboratory are controlling; in mathematics, it is the discipline found in the head. The personal nature of this discipline has meant that mathematicians have had to develop a special sort of devotion to the significance of their own work and of the importance of sticking right to it, no matter the distraction.

Another version of the explanation reads as follows: Each tightly knit group of scientists has its own group ethos. I am told that in physics an older man is often expected to give up active research work in favor of committee assignments, and he is honored when he does this. In mathematics it is clear that an older man who gives up research for such other activity really loses caste with his fellow mathematicians.

There are plenty of other purported explanations as to why mathematics is not part of the establishment. I don't intend to try to decide here between these explanations, first, because I'd rather leave the debate to my audience, and second, because I think the relevant question is: Should mathematics in the future join the establishment?

There is an unselfish reason why mathematics should be part of the establishment. Science is an interplay between theory and experiment; the American empirical temper tends to give priority to experiment. As science matures—and with massive financial support it will do so rapidly—the theoretical aspect will become more important and with it mathematics as the clearest and most general form of this aspect. For this reason, if for no other, mathematics belongs in the establishment. It might even be that the President's Science Advisory Committee, which now and again likes to pontificate about mathematics, should consider again having a mathematician as member.

There is also a selfish reason why mathematics should be part of the establishment. Unless mathematics does become part of the establishment, fundamental decisions about its support will be made by people of enormous good will who profoundly misunderstand the nature of mathematics.

Sometime *after* I wrote that apparently grandiloquent phrase about people of enormous good will who profoundly misunderstand the nature of mathema-

tics, I came across an apt illustration. On August 6th last occurred two acts of folly: Saunders MacLane tried to demolish an automobile windshield and Alvin Weinberg tried to turn the teaching of calculus back 40 years. MacLane's act showed an abysmal ignorance of the laws of physics. I hope Alvin will pardon me if I say that his article in *Science* ("But is the Teacher also a Citizen," *Science*, August 6, 1965) displayed great political sagacity, enormous good will, and abysmal ignorance of mathematics. He observed—and I would say correctly—that good teaching of calculus is of interest to other sciences. He noted that a physicist friend of his had written a text on calculus which (in Weinberg's words) "presents the traditional parts of the subject that have been bypassed by the professionals" (such as skill in handling simple integration). Now as long as it is clear that calculus is not a branch of physics we can certainly welcome physicists—or chemists or economists or logicians—who take the interest to write texts in mathematics. In this case Weinberg doesn't make clear whether his physicist friend wanted to train students to reproduce B. O. Pierce's "Tables of Integrals" or to train students to do many problems in volumes, work, moments of inertia, water pressure, and the like. Now any good calculus course must have many good problems; these particular ones are of the duller sort, of less interest to most users of calculus and even of less interest to those physicists who believe in the eight-fold way. In any case, Dr. Weinberg should have realized that his vague statements could only be interpreted as a call to return to the style of teaching best described to this audience as Granville's *Calculus* (now Granville, Smith, and Longley). Since that was the style 39 years ago when I first started studying calculus at the school where Granville, Smith, and Longley had all taught, I have some evidence for the observation that Weinberg inclines to turn the clock back 40 years.

Pardon me. Weinberg's article recommends (though it may not exemplify) careful scholarship. If I draw my conclusion carefully, I must argue that it is proposed to turn the clock back not 40 years, but just 39 years.

6. The apportionment of federal funds. This should be enough to demonstrate that the country and mathematics both suffer when mathematics is not represented in the establishment. This will matter more in the future because there will be hard decisions to make. Perhaps the toughest decision will be this one: Given substantial federal support of science as a whole, how does one divide this support between the various sciences or between the different branches of one science? Once the government is giving large scale support to science, it becomes essential to ask this question. I wish this were not so, not just because *I* don't know how to answer the question, but because, as far as I can see, *no one* now really knows how to answer this question. Neither the scientists nor the politicians have been accustomed to this sort of decision about science; in the past, this allocation decision has usually been avoided. (One might almost say: The decision is "locally avoidable" but not "avoidable in the large.") At the beginning, when the government first supported science, one could say: Support

all competent scientists. This will work for a few years. It simply doesn't work indefinitely, partly because it is not too easy to define what one means by a "competent" scientist, and partly because the distribution of government funds presently influences the subjects which the competent people take up.

Let me offer some examples to show how hard it is to apportion money between the sciences.

First example: What sciences do you include? Do you include social sciences? At present, it is my understanding that the National Science Foundation includes those social sciences which choose to bear the label "Behavioral Sciences" and which are in addition quantitative. Personally, I don't think that a label "Behavioral," even if invented by the Ford Foundation, is an answer to our problem. I also wonder if the requirement "quantitative" might not in a few years lead to some fanciful quantitative decorations of important research which ought not to be quantitative at all.

Second example: How do you divide money between "pure" and "applied" mathematics? I have no answer to propose. I simply observe that all the present noisy controversy about applications does not provide an answer either. In mathematics, it is right and proper that each of us be enthusiastic about his own work. Well placed enthusiasm for pure mathematics does not decide against applied mathematics. Well placed enthusiasm for applied mathematics does not decide against pure mathematics, even in those cases when the public enthusiasm for the application is coupled with considerable ignorance of what goes on in pure mathematics. At present, I see no statesmen with a good view of the whole picture.

My *third example* is a question to each of you personally: How many specialists should there be in your own field of mathematics? You say "more." How many more? Think a bit and you may find some of the hidden booby traps. If, say, there were ten times as many mathematicians supported in your field, there would be ten times as many papers to read and ten times the chance that your own results would be scooped.

Let us continue. Suppose that someone has finally answered the question about distribution of government funds between fields of science. But now, just within one field, the government supports many types of activities: research, education, teaching, facilities, conferences, and the like. For mathematics, most of the support funnels through the National Science Foundation, more exactly, through a wide variety of "Programs" in that Foundation. For many years I have been puzzled as to how and where someone with a real understanding of mathematics makes a wise decision on the relative levels of these activities. Gradually I have come to the regretful conclusion that *no one* makes a wise decision here. It just happens.

An example. In 1966 the International Congress of Mathematicians will be

held in Moscow. Now international congresses are big and unwieldy and have all sorts of troubles, but the fact remains that mathematics (with astronomy) is the most international of sciences and that our ablest young research mathematicians get vital stimulus and encouragement for future projects from meeting their colleagues from other countries. At previous international congresses, I have myself seen many explicit examples of such profitable contacts between young mathematicians of different countries. Let me add that in my judgement the United States today has the best mathematics in the world. I can say this because it is not my generation of American mathematicians which brought this about. Ten years ago we were not best; ten years from now we may not be best but in recent years our younger mathematicians have done wonderful things; at the last International Congress one of the two Fields medals for outstanding achievement by younger mathematicians was awarded to an American. (Added in proof: At the 1966 Congress, two of the four Fields medals were awarded to Americans.)

What conclusion? At the next Congress there should be a strong representation of the ablest young American mathematicians. How will they get there? The chief source is a possible NSF grant to the American Mathematical Society. I am informed that this grant will be $20,000. Think a minute. Twenty thousand dollars. Enough to send twenty young men, possibly twenty-five. How does this compare? How much does the NSF spend on travel expenses for people coming to *this* meeting in Ithaca? Much more, I suspect. How much does the NSF spend on summer institutes for high school teachers of mathematics? Much more. How much does it spend on summer salaries? More. How much does it spend in a four-year period to support the committee on the Undergraduate Program in Mathematics? About one hundred times as much. How much does it spend on the Committee on Educational Media? More. How much did another government agency spend this summer on a conference on categorical algebra (my subject)? More.

It is *not* my intent to question *any* of these expenditures. I admire the vigor of the program director for each of these activities and the devotion and self-sacrifice of the mathematicians who administer each.

It *is* my intention to draw a comparative judgment about these activities. Do you share my conclusion that a grant of $20,000 for travel expenses to the International Congress of Mathematics is just ridiculously small? If you share my conclusion, you are at liberty to write to John Wilson of the National Science Foundation. Feel free to differ with my own numerical estimate, which is that there should be about $100,000 for such travel expenses.

This was just an example. The intended point is this: Given one field of science, say mathematics, there are hard decisions as to the relative levels of Federal support of different sorts of activity in that science. I am personally not convinced that the National Science Foundation (or for that matter, anybody else) knows how to bring *wise* and *active* knowledge of the science itself to bear on these important decisions.

7. Centers of excellence. Here is a third type of hard decision about science. Where do you locate scientific facilities? At present, the Science Foundation has a program to develop what it chooses to call "centers of excellence." This is a program which is understandably popular: 90 percent of the universities of the country at first blush might hope to be one of the new centers. This popularity doesn't necessarily mean that the program is a good one. Some wag, noting that excellence is a rare quality and that "centers of excellence" was just a slogan, observed that the program might really turn out to be one developing "centers of mediocrity." Be that as it may, the process of deciding which of ten competing institutions in a given area is the one to become a center of government support is a pretty tough one. I have carefully examined the texts of all the congressional hearings where the Science Foundation defended this program. From this examination I was unable to find one scintilla of evidence that the Science Foundation had given any careful and considered thought to the decision process which will be required. To put my conclusion bluntly, I hold that the administration of the Science Foundation and the NSF Board have been irresponsible in starting this program without careful advanced consideration of the decision process involved.

Since I am sure this conclusion will shock many of you, let me ask you to examine quickly the situation in mathematics. Recent developments have clearly demonstrated that the major mathematical centers are no longer individual universities but congeries of first class universities. I give you Princeton, New Jersey; Cambridge, Massachusetts; Paris, France; and Moscow, USSR as examples. In other words, the development of our science appears to flourish best when mathematicians come together in larger groups. At the same time the development of our politics suggests that each of 50 states would like a center of mathematics in that state. This paradox is the source of a real problem.

Let me put the matter differently. Well into the 20th century American mathematics, though vigorous, was essentially provincial. Our great heroes were often typical provincial heroes. One such example is my own revered teacher, E. H. Moore, to whom I certainly owe a great deal. Today, as a result of long efforts, American mathematics has come of age, thanks to a massive injection of European talent, much of it from Hitler Germany. As late as 1950, a count at the then three leading universities for mathematics in this country, showed that approximately 50 percent of the full professors were not trained in this country. Today American Mathematics does stand on its own feet, and this thanks to a new generation. However, the doctrine of regional development and regional centers of excellence is often advanced hand in hand with the doctrine that provincial heroes of American mathematics should not only be admired—and they should indeed be admired—but that they should be imitated. I hold that Government support of such reversion to the provincial would be fatal.

8. Summary. To summarize, I have cited three basic questions of government policy about mathematics: How do you distribute money between branches of mathematics? How do you distribute money between different

activities in mathematics? How do you make geographical decisions? I have not hesitated to indicate here and there my own opinions. My chief opinion is this. At present we do not have either the mechanism of decision or the wisdom necessary to make such decisions properly. Also, I think I can explain why these decisions are so hard. Political decisions are made by majority vote, and scientific decisions cannot be made by majority vote. The decisions which face us are both political and scientific—what do we do?

In closing I would like to make three explicit recommendations.

First: In selecting members of the scientific establishment, eagerness to serve has in the past played far too great a role. Actual and significant scientific accomplishment—and I mean scientific accomplishment and not administrative accomplishment—should in the future play a much bigger role if we are to be able to decide well the problems before us.

Second: Minority opinions as of science policy should be vigorously encouraged. Committee reports should not try to be unanimous.

Third: There should be a recognized avenue by which working scientists can express their opinions on science policy. I suggest that such an avenue might be a journal of science policy open to contributions from any qualified scientist. At present, what we have are effective means of disseminating *to* the scientific community the opinions of the Washington establishment. What we need is a feedback.

Members of the Association: Now it is your turn to feedback.

WHAT CAN MATHEMATICIANS DO FOR THE FEDERAL GOVERNMENT?

JOHN W. TUKEY, Princeton University and Bell Telephone Laboratories

1. Introduction. All of my title but "ian" was assigned to me; I assume that we all understand the title to mean "for the Federal Government and thus for the Nation, and for the World." If I wanted to give a useful impression by making untrue statements, I could answer: "almost everything except mathematics" and "by working on uncomfortable problems." These statements are untrue because, as we shall see, there is much of what every mathematician judges to be his natural work, pleasant to do, to be done "for the Federal Government." On the other hand, these statements are useful and help to give a correct impression, because many mathematicians seem to feel that *they* themselves should do only mathematics. Undoubtedly some are right.

Each of you owes it to yourself, to your college, university or other organization, and to your country to work out the places and ways where you can do the most.

2. Kinds of "us." A decade or so ago someone made amusingly distorted maps labelled "A New Yorker's idea of the United States," "A Bostonian's idea of the United States" and so on. They reflected the attitudes back of the story of the maiden lady from Boston who made a safari by automobile to California and back, and who, when asked about the route, said: "I forget how we went, but we came back by way of Dedham."

What is the parallel caricature of a mathematician's idea of society? I suggest a simply-ordered structure of seven classes:

(1) Mathematicians in the narrow sense.

(2) Mathematicians in the broader sense, including mathematical physicists, mathematical statisticians, and mathematical logicians.

(3) Legitimate users of mathematics, including physicists, statisticians, some engineers, some chemists, etc.

(4) Other technicians and scientists.

(5) Other intellectuals.

(6) People at large.

(7) Administrators.

I am glad that this is so largely a caricature, for the good of each of us, our profession and our country. But it would be unrealistic not to recognize that it has shreds of truth.

One who speaks on my subject should make it clear where he stands among these classes. Once upon a time, I was briefly a mathematician in the narrow sense, say from 1938 to 1941. Since then I have been a mathematician in the broad sense on a part-time basis, with a large share of my time spent as a legitimate user of mathematics, mainly in the fields of statistics and data analysis. Please discount my words accordingly.

3. Education, including research. The first of the three heads under which it is natural to outline the ways that mathematicians do things "for the Federal Government" and thus for the nation and mankind, is education, including research carried out in educational institutions.

For the last 20 years, the major supporter of mathematical research, of all kinds, has been the Federal Government. By doing better and more effective research many mathematicians serve the nation and the world through the Federal Government.

The Federal share in the support of graduate training is not quite as large as it is in research, but good, efficient, and diversified graduate training is more and more important to our country and more and more supported through Federal actions.

The improvement of mathematics education in the schools, which I am happy to see becoming more and more a continuing activity entered into by all kinds of mathematicians, has been largely supported by Federal funds.

These are certainly among the things that all mathematicians feel that mathematicians should do. For all of this agreement, such areas are not free of strains, either now or in the future. Year by year, a larger fraction of our young people complete high school, enter college, complete college, enter graduate school, get master's degrees, get doctor's degrees, do post-doctoral work. For the next decade or two, at least, not only fractions, but sizes of age groups will increase. We face real problems of teaching both those who will leave the academic world and those who are so badly needed to become teachers themselves. There have always been readjustments in the details of how we train students; these readjustments will have to come more rapidly and in larger steps. In particular, we are going to have to provide greater diversity, both in types of training and in fields. The rise of the computer, to take one example, will call for more and more people with a strong master's background in most fields of mathematics combined with an increasing logico-linguistic understanding of formal modes of communication and translation.

Those who speak out against the "new mathematics" in the schools will have to be encouraged to bring together the necessary insights and skills and develop "new curricula" of their own. There is no substitute for fair and open competition; I hope to see a strong enough group willing to work hard on *new* approaches in yet another direction to deserve and receive Federal support.

Throughout the educational system, the responsibility of individual mathematicians must be to support diversity and competition wherever these have strength enough to survive and be effective. In many cases, support need only mean not standing in the way, not supporting some single monolithic position, not impressing on students that only one way is right. In others, support means setting out to cooperate or lead in new ventures. All can help.

4. Technical contributions. The second main head is the doing of mathematics outside departments of mathematics.

At one extreme stands direct government service. Once the people who worked directly for the Federal Government and appeared on our membership lists were few and exceptional. Today the number is vastly increased, and so is the diversity of the branches of government that employ them. Between membership lists, articles in journals, and conversation with friends, most of you have some idea of what kinds of people are involved and what they do. I wish I could help you understand the situation better, but my own contacts are about as spotty as your own. It would be a major effort to come to a clear understanding of where we stand today, to say nothing of where we will be tomorrow.

I ought, however, to point out, rather than describe, the major contributions of mathematical thinking, by mathematicians, behind the classification barriers of the National Security Agency. It is probably here that mathematical thinking has contributed the largest share to the activities of any Federal agency.

Throughout the Federal government, with few exceptions, the mathematician contributes as part of a mixed team. Almost all the exceptions correspond, at least roughly, to a "department of mathematics" in a substantial research establishment. In my view, this is as it should be. The best place to get research for research's sake done is still the university full of graduate students, best for the research, and best for the by-products. This has not kept Federal agencies, however, from employing many mathematicians in interesting and rewarding careers.

There are also many mathematicians involved in work under government contracts, in industry proper, in the "porch laboratories" that are really neither in nor out of the government's "house," and in universities and colleges outside of mathematics departments. Again what is done is very diverse, and hard to picture as a whole. Times are changing, perhaps slowly; the fraction of such work that is directly connected with defense is dropping steadily; the types of work being done are steadily diversifying. Take a few "porch laboratories" as examples. How different from each other are the things done at RAND, at the National Center for Atmospheric Research, at Los Alamos or at Brookhaven and Argonne. Both the kinds of problems, and the kinds of mathematics are diverse and becoming more so.

Finally, consider technical consultation on government work, which I should like to separate clearly and carefully from advisory consultation, which will be the next main topic. There is more of this, I suspect, than most of us realize. Mathematicians can do mathematics unobtrusively: for government contractors, for university projects in other fields, or directly for government agencies. As a consequence, it is very hard to get any clear idea of how much of this is done, on what sort of problems, involving what sort of topics.

I have no feeling that too much is being done, rather I would suspect not enough. It is not necessarily easy to be effective in such work; someone must build a bridge from the problems to the mathematics. Usually the mathematician must at least help with this task, which is often rather unfamiliar to him. I do not know what can be done to make such cooperation easier and more

effective. Perhaps there is a need for local or regional unofficial employment centers or mediators. Opportunities for such work are much more diversified than most of us realize. In particular, some of my friends who study the human brain from a physiological point of view are concerned about how much more mathematical help some of their Russian competitors seem to have. This is but one example.

5. Advice and administration. The third main head under which mathematicians can serve the Federal Government, the one which presumably accounts for my selection to appear here today, is advice and administration. Let us survey the field briefly, and then return to the areas where my own experience may be illuminating.

One of the major paths of Government consultation is provided by the National Academy of Sciences—National Research Council. The individual members of the Academy, elected by the general membership at large on the basis of demonstrated scientific ability, accept a responsibility to advise the Federal Government as part of their acceptance of membership. The divisions of the closely-affiliated National Research Council are made up of both representatives of scientific organizations and members at large, together with liaison representatives from appropriate government agencies. Activity of mathematicians in advising the government through the NAS-NRC, both through the Division of Mathematics and through committees more broadly responsible to the Academy-Research Council as a whole, has increased substantially in recent years. Some of our colleagues, including my friend Sam Wilks, now gone from among us, look to a very considerable expansion of NAS-NRC activity by mathematicians, especially in connection with problems not primarily mathematical. For my own part, this seems right, natural, and inevitable.

One major activity of the Academy-Research Council's Office of Scientific Personnel is the annual screening and ranking of applicants for all kinds of fellowships offered by the National Science Foundation. Here the mathematicians have always played their part, thoroughly and effectively.

Advice to granting agencies—to NSF, ARO, OAR, ONR, NIH, and so on, or, if you are so unmathematical as to prefer words to symbols, to the National Science Foundation, the Army Research Office, the Office of Aerospace Research, the Office of Naval Research, the National Institutes of Health, etc.—is given in varying amounts and patterns, both on the relative quality of individual grant proposals and on broader questions of policy. Much of this advice is discipline-by-discipline. Mathematicians have long participated effectively at a variety of levels. Not all such advice on policy concerns grants for research in mathematics, since the NSF Office of Science Information Services has a statutory Science Information Council upon which mathematicians have served.

Then there are the working agencies of the Federal Government, by which I mean agencies concerned with doing things "in-house." (Clearly an agency can be both a granting agency and a working agency.) There are many advisory

committees here, whose scope varies from quite narrow to very broad, from specific aspects of the work of a bureau to large parts of the work of a department. Here mathematicians are also to be found, perhaps not in as large numbers as there ought to be, but probably in larger numbers than many here in the audience would expect.

Finally there is the Executive Office of the President. Here too mathematicians play a part: on committees advisory to the Office of Statistical Standards, on panels and subpanels working in the Office of Science and Technology, even at times on the President's Science Advisory Committee.

Between advice and administration stands the National Science Board, with statutory responsibility for many of the activities of the National Science Foundation. The Board's role is still evolving, but however this evolution may turn, its importance for science in this country will remain great. Here "Jimmie" (E. J.) McShane upholds the laurels of mathematics with wisdom and humor and Mina Rees makes it clear that mathematics is something important to learn, something to be more learned than taught.

Administration, which is fortunately almost always a matter of individuals rather than committees, even in the Federal Government, is not barred to mathematicians. In my student days, for example, Luther P. Eisenhart and R. G. D. Richardson were deans of important graduate schools. Today mathematicians help to administer the Federal Government. Of the five or six Ph.D.'s who bothered to come to commencement in person for their Princeton diplomas in 1939, three were mathematicians. I am here today, Ralph Fox is in Japan recovering from an emergency appendicitis operation, and "Joe" (F. J.) Weyl is shouldering a large share of responsibility for the affairs of the Office of Naval Research. Today Brockway MacMillan is the Undersecretary of the Department of the Air Force. The administrative doors are no more closed to mathematicians in government than they are in industry or the universities.

6. The advisor. Of all these roles for a mathematician, being an advisor is the one with which most of you will have had the least experience. Research and teaching have long been before our eyes; examples of most kinds of technical contributions are easy to find, university and college administrators are always nearby, even if often misunderstood. The advisor is something else, and for good reason. One requirement for effectiveness is often unnoticeability.

What can we say of his duties, his motives, his actions, his rewards?

First, and perhaps foremost, he is not there as a representative. If there is a mathematician on an advisory group, he ought not to be there as a representative either of some abstract impalpable entity called "mathematics" or of an informal trade union of mathematicians. If he acts as such a representative, he will do less than justice to his opportunities, less than justice to himself, to "mathematics" and to the government. If he were put on to "represent" mathematics, those who selected him failed to do justice to their own opportunities.

There are many good reasons why he may have been chosen: sometimes

because his background will tend to ensure a certain point of view being properly considered; occasionally, perhaps, because his technical knowledge will be helpful (this has happened to me very infrequently and, even then, usually in statistics rather than in mathematics proper); even more likely, perhaps, because he has a fresh and able mind willing to take a look at a new problem. Those who pick mathematicians for such reasons, and those mathematicians who serve as if they had been picked for such reasons, do take proper advantage of their opportunities.

All of us, mathematicians or not, have individual backgrounds and interests. How much should we let these influence us? When are we being unduly biased? These questions come up, consciously or subconsciously, when any reasonable man serves as an advisor. There is no simple answer to these questions. The middle way is needed, and may not be easy to find. The man who tries to gain as much as he can for "his own" interests usually fails to get those things which he might have had, for the rest of the group will soon recognize his bias and discount his views overwhelmingly. The man who leans over backward fails to serve anyone. The proper choice, the middle way, is to think as hard as you can about the general welfare, as seen from your own background and experience, and then urge those things that seem to you best fitted to meet its overall needs. Your background will then be appropriately represented, you will be doing what you can for those who appointed you, and you can be happy with your conscience. You owe the government the best insight and understanding you can offer, not just your initial prejudices, not just what you think your friends would like you to say.

I think it is fair to say that there are two separable qualities of importance in an advisor, besides the ability to work with others in reaching a common position on both policy recommendations and action recommendations. These are acuteness and wisdom. As you serve on advisory groups you cannot help learning that these are not the same. A good advisory group needs both. Members who provide either are well worth their salt; those who provide both are doubly valuable. If you become an advisor, you will have to learn what balance of acuteness and wisdom you ought to bring to each particular group.

There is often even a place in an advisory group for a mild enough form of an *enfant terrible*, but only to the extent that such behavior comes naturally, and with some concern for others. I have heard respected advisory colleagues speak with affection of a former member, indicating that it was too bad that so-and-so is no longer here; he was always wrong, but his remarks often helped to clarify matters.

Being a good advisor, then, requires a willingness to work with others, and to argue with them when necessary, an honest attempt to assess the general good in broad and honest terms and to be acute, or wise, or both, as the needs for the particular group and your own abilities combine to indicate.

7. A consultant defined. Both an advisor in the sense just described, and a technical advisor in the usual sense, are instances of consultants. There is a

simple definition which can teach us much: *A consultant is a man who thinks with other people's brains.* He rarely has the time to become an individual expert on all the things involved in the issue at hand. He must—and often this is easier to do as part of a group—come to use the various experts' brains as essential tools in understanding the problems before him. Too often he will need to use their brains, and not just their words. Doing this is important in many different circumstances, from the most technical to the highly administrative.

The ability to do this, much of which can be learned, is not a substitute for wisdom, but is often essential in providing wisdom what it needs to feed upon.

8. Apprenticeship. As mathematicians we are familiar with growth, experience, and testing. Any institution that chooses department heads, research professors, or even long-appointment assistant professors unwisely, will suffer. Any agency that picks its advisors unwisely will suffer too. As a result there has to be some sort of an apprenticeship system for advisors, as well as for professors, a working up from less dangerous committees to more dangerous ones.

An advisor usually has to begin by advising on rather unimportant problems at first. To make matters worse, working on these problems is likely to be almost as uncomfortable as working on the larger ones.

9. Privacy and publicity. The problem of privacy is always important, and sometimes crucial. Both those who are being advised and those who advise have rights and responsibilities. At one extreme stands the President, who, with his personal advisors, is entitled to complete privacy, even as against the inquiries of the Congress. His advisors have no recourse, even when they are publicly criticized for not giving specific advice they may, or may not, have already given privately and urgently. At the other extreme stand groups publicly announced as having been asked to study some problem and to make a report with recommendations.

There is no single principle of universal application, but there is surely no excuse for the advisor in private who cannot bear to have his recommendations not accepted, and who goes directly or indirectly to the newspapers. There is a real difference between being asked to volunteer advice and agreeing to work as an advisor. The latter implies a sense of responsibility and an acceptance of team play that is often absent from the former.

So far as I have seen, those concerned with giving advice related to matters scientific and technical, whatever their own discipline, have behaved responsibly about publicity. I have emphasized their responsibility here, because I hope, and expect, that this will continue to be true in the future.

The relation of the advisor to politics may also be crucial. There is a place for both the advisor who has a public position on political issues, and the advisor who is prepared to offer the best advice he can, no matter who is in power. It is right that advice about matters scientific and technical should affect politics quite explicitly; it is important, on the other hand, that administrators should have competent advice whatever their prejudices or policies (although successive groups of advisors may find it necessary to resign).

The President's Science Advisory Committee has established a short but important tradition of responsible advice to the President, whoever he may be. As a consequence, new Presidents, though they had every right to do so, have felt no need to interrupt the orderly progression of terms of service on this Committee.

I received one letter, I presume from a member of our Association, who felt that Viet Nam made the topic of my talk wholly uninteresting, since he wanted nothing at all to do with the Federal Government. This is a view any mathematician is clearly privileged to take, but there are other forms of protest better suited to most of us. If this nation is to survive, and its people are to live decently, there will be a real need for the best advice any of us can give about scientific and technical matters, whatever the broad policies of the government, foreign or domestic, may be. Revolution may or may not be a constitutional privilege, but short of revolution some of us must support the orderly workings of our government with whatever wisdom or acuteness we can find.

10. Advice to legislatures. Much has been learned by experience about the practice of advising the executive branch of the Federal Government. Much less has been learned about advising the Congress, where there is still much to be learned. Recent developments suggest that both sides are indeed learning how this is to be done effectively. It is to be earnestly hoped that whatever we learn will find further use, not only in providing helpful advice to a greater variety of congressional committees, but also in the advising of state legislatures.

11. Some problems of the "day." It is easy to look ahead and see major problems before us, before all the people of this country, in which scientific and technical matters play an important part. In a moment I shall mention a few of the more obvious and difficult. No one of them can be decided on purely scientific or technical grounds. To be spared the responsibility of working on any of them would make anyone's life simpler and more pleasant. But many, both scientists and others, will have to do what they can to clarify the issues and offer good advice.

Is science being subverted? This question is raised too frequently these days to be avoided in the long run, though it seems to mean many different things to different people. There are those who feel that the name of science is holy, and should be separated from everything that is only a reasonable choice, rather than an established fact. There are those who are concerned that science is becoming "little more than an instrument for the continuation of politics by other means." These are questions on which no category of people is likely to find unanimity. Yet there will be a great need for a gradual consensus.

How is the Federal Government's support for science and technology to be allocated? Notice that I said "allocated," NOT "divided," NOT "shared." We come ever closer to the point where "either-or" decisions will involve widely different fields.

How will we learn to live with our environment? Here there are many subsidiary questions, each of major proportions:

What is a just balance between those who would "preserve everything" and those who would "exploit freely"?

How can we pay a fraction of the attention that we have so long paid to how we take substances from our environment to the equally important problem of how we return substances to it?

What are the real technical issues in connection with population growth? Are rates of growth or total numbers more crucial?

And so on. As mathematicians we know that in mathematics on the average, every solution uncovers several new problems. Matters are not different in the affairs of our country.

12. Mathematicians and the problems of the day. Mathematicians can help with all of these problems if they truly wish, but not by doing mathematics, not by working on things that are enjoyable to work on. Instead they will have to give up the protection of unquestioned hypotheses and contribute their best acuteness and wisdom under uncomfortable circumstances. Some will do this; I trust more than in the past. They will not begin at the top by working on the sort of problem just illustrated. Rather they will serve apprenticeships on small bothersome problems, and work their way up.

For others this will not be the better path of service. They too can do much for the Federal Government and the nation by serving in more "mathematical" ways.

There is one thing that all of us could do; I believe almost all of us can learn to do it. That is to come to believe, and to impress upon our students, that all of these varied kinds of service are good, that some are called to one and some to another, that each should seek a way in which he or she will come as close to excellence as possible.

It is not easy to give such an impression, for it is not enough to say such things. If you do not feel them, if you do not live them, your students will behave as if you never said them.

This Association was founded because mathematicians had to be concerned with teaching as well as research. Its members need now to recognize even broader responsibilities.

HARLEY FLANDERS	J. R. MAYOR	

EDITORIAL CORRESPONDENCE AND MANUSCRIPTS OF PAPERS should be addressed to the Editor, R. A. Rosenbaum, Wesleyan University, Middletown, Conn. 06457.

ADVERTISING CORRESPONDENCE should be addressed to RAOUL HAILPERN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

NOTICE OF CHANGE OF ADDRESS by members of the Association as well as correspondence regarding subscriptions to the MONTHLY should be sent to the Executive Director, H. M. GEHMAN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

NOTICE TO AUTHORS

The MONTHLY welcomes papers presenting valid mathematics, of rather general interest, at a level intelligible to persons with two years of full-time graduate study. Some novelty of content, viewpoint, or arrangement is essential. Expository articles are particularly desired. State the context and the principal aim of the paper early. Address yourself quite explicitly to the reader described above, communicating your ideas to him clearly and attractively.

The title should be brief and meaningful. Since the title will be quoted and reproduced by laymen, it should contain no symbols unfamiliar to laymen.

Articles should be typewritten, double-spaced, on $8\frac{1}{2}\times 11''$ paper of very good quality. Submit the original (and a duplicate if convenient) keeping a complete copy for yourself. To avoid loss and delay notify us of any change of address.

The typescript should be prepared with extreme care. Misprints are highly obnoxious; so are dangling participles. Put name and address between title and text. Put references at the end with bracketed citations in the text. Avoid footnotes; instead, use clearly designated remarks in the text. Put acknowledgments at the very end, just before the bibliography. Be generous with spacing and displays. *Keep notation simple.* For a matrix the notation $[a_{jk}]$ is recommended, with det $[a_{jk}]$ or $|a_{jk}|$ for the determinant. On doubtful questions regarding format or notation, observe practices in current issues of the MONTHLY or consult the applicable sections of the "Author's Manual" of the American Mathematical Society.

Annual dues for members of the Association (including a subscription to the American Mathematical Monthly) are $6.00. For nonmembers the subscription price is $10.00.

PUBLISHED BY THE ASSOCIATION at Menasha, Wisconsin, and Buffalo, N. Y.
during the months of January, February, March, April, May, June–July,
August–September, October, November, December.

Second-class postage paid at Menasha, Wisconsin. Acceptance for mailing at special rate of postage provided for in the Act of February 28, 1925, embodied in Paragraph 4, Section 538, P. L. and R., authorized April 1, 1926.

THE ROLE OF THE AXIOMATIC METHOD

R. L. WILDER, University of Michigan

Ever since its importance to the development of mathematical theory has been realized, much has been written on the axiomatic method. However, except for the work of a few pioneers of the early part of the present century, such as Skolem and Tarski, most of this writing has been done during the past 20 years, roughly speaking. It took the mathematical world a long time to realize the potentialities of the method—and, we should add, to recognize its limitations —and it is undoubtedly true that even today some eminent mathematicians deplore its widespread use. The point of view taken by both Poincaré [**10**] and H. Weyl still survives. Although recognizing the accomplishments of the method, Weyl felt that its fertility was "approaching exhaustion" [**15**]. He made a firm plea for a return to problems of "mathematical substance" which, he maintained, form the basis for the concepts subsequently cast in axiomatic form. Both Poincaré and Weyl were intuitionists of sorts; they believed that mathematics can not be reduced to axiomatic form without sacrificing something of its true nature. They did not deny that axiomatics is a legitimate tool, but only as a device for giving precision to already created mathematical entities—a kind of classifying or cataloging function, much as the present-day intuitionist considers it to be.

It therefore seems timely to reappraise the role of the method, particularly in view of recent developments in mathematical logic; and to gain proper perspective for the task, it appears that we should begin with a short review of its evolution. In studying the evolution of mathematical concepts, I have found it convenient to distinguish between those cultural stresses which influence the development of concepts, according to their "hereditary" and their environmental aspects. For example, the inception of most early mathematics, such as arithmetic, and geometry in its primitive forms, was due to environmental forces; but the axiomatic method occupies a unique position in that it appears to have owed its inception chiefly or even entirely to hereditary stresses. In other words, the factors which forced its creation were based on internal rather than external needs. Of course, because of the dearth of knowledge concerning early Greek developments, one cannot be absolutely positive about this. However, most historians seem to agree that crises, attendant upon the attempts to cope with paradoxes such as those of Zeno, compelled the formulation of a basic set of principles upon which to erect the geometrical edifice. The introduction of the method carried with it a tacit acceptance of certain types of logical reasoning; thus logical deduction was applied to mathematics for the first time.

Accordingly, it seems reasonable to regard as the chief role played by the axiomatic method in Greek mathematics, that of providing a consistent foundation. In considering this role, we should note two aspects of the method: (1) The manner in which logic was brought into mathematics; indeed, both the *motive* (namely, to achieve a *consistent* system) and the *methodological aspect* (logical

deduction), tended to make mathematics subordinate to logic; (2) there was presumably only one interpretation of the geometry described in the *Elements* —in modern terms, only one model. Primitive geometry, like arithmetic, grew out of the need for coping with the physical environment; and by the Greeks, geometry, even after it was formulated as an axiomatic system, was apparently still considered a science of physical space. Consequently, what we would call the primitive terms were not variables, but constants referring to the single spatial model.

For the next major change we must turn to the 19th century. Space does not permit going into the factors that produced the change; with the advantage of hindsight we can perceive signs of it even earlier. It has been customary to attribute the change to the introduction of non-euclidean geometry. But as Freudenthal recently recalled [4], there was little evidence of excitement or even interest in the mathematical community regarding the work of Bolyai and Lobachevski, for at least 30 years after its publication. And meanwhile other writers such as Peacock in algebra, Whewell in mechanics, and Boole in logic, clearly brought out the concept of attributing to the primitive terms of an axiomatic system the undefined character that we give them today. The later impact of the admissibility of non-euclidean geometry into mathematics only promoted an evolution already under way.

Thus, in his *Mathematical Analysis of Logic*, 1847, Boole stated, relative to his symbolic algebra, "the validity of the processes of analysis does not depend upon the interpretation of the symbols which are employed, but solely upon the laws of their combination. Every system of interpretations which does not affect the truth of the relations supposed, is equally admissible" Nevertheless, after it was recognized that the non-euclidean geometries are just as consistent as the euclidean, there seems to have been a general feeling that both the euclidean and the non-euclidean systems were still only candidates as potential sciences of *space*. Witness the attempts to determine, both on an earthly and on a cosmic scale, whether the sum of the angles of a triangle is really 180°.

However, geometrical thought gradually fell into line with that in other fields; the publication of Pasch's *Vorlesungen über neuere Geometrie* in 1882 helped especially to establish the variable character of the primitive terms. In Nagel's words, "No work thereafter held the attention of students of the subject which did not begin with a careful enumeration of undefined or primitive terms and unproved or primitive statements; and which did not satisfy the condition that all further terms be defined, and all further statements proved, solely by means of this primitive base" [7].

However, considering the primitive terms as undefined is not the same as conceiving of them as variables, and evidently the transition in point of view was, like most fundamental mathematical conceptions, a slow process. Certainly the works of Grassman, Pasch, Peano, Padoa, Hilbert, and Russell, to name but a few of those involved, all contributed to the evolution; and by the early part of the present century the notion was certainly recognized if not com-

pletely assimilated. This is evident in such works as those of Fréchet on abstract spaces, and of E. H. Moore in general analysis; in the axiomatic formulation of the theory of groups; and in Hausdorff's axioms for a general topological space. In lectures given during the summer of 1909 at the University of Illinois, subsequently published in his *Fundamental Concepts of Algebra and Geometry* in 1911, J. W. Young stated at the end of his concluding lecture: "We may regard the undefined terms in an abstract science (by which he meant an axiomatic system) as *symbols* (ital. mine) representing *any* entities for which the fundamental assumptions appear to be satisfied." Certainly here the notion of the primitive terms as variables appears to be recognized.

I am trying to bring out by these remarks another historically important role played by the axiomatic method. I pointed out that the role of the method in Greek mathematics seems to have been to provide a consistent foundation for mathematics—a twofold objective, namely the provision of a *foundation* which at the same time met the then current charges of *inconsistency* (the second objective may well have been the motivating factor). During the period covering roughly the latter third of the 19th century and the first third of the 20th century, we find the axiomatic method playing a new role, namely that of introducing increasing abstraction into mathematics. E. T. Bell [1; p. 239] dates the period from 1879 to 1920, placing the emphasis upon the theory of groups which during this period received a thorough axiomatic treatment. But it is clear from Bell's own subsequent remarks that the credit really should go to the axiomatic method itself; some twenty-eight pages later he states explicitly, "The postulational method is the source of both the modern critical movement and abstractness."

(Incidentally, I have no intention of commenting upon whether the abstract character of modern mathematics is a good thing. I wish only to point out the role of the axiomatic method in the development.)

Before passing on to the current situation, I must mention an instance in which the axiomatic method was again called upon to serve the function, originally exemplified in Greek mathematics, of trying to establish a consistent foundation for a theory. After the Cantorian theory of sets was found to harbor contradictions, Zermelo published [14] his famous set of axioms using "set" and "element of" as primitive terms. The analogy with the Greek situation, as the latter appears to us through the haze of centuries, is striking. In both situations, crises had developed which threatened the security of mathematics; and in both cases resort was taken to explicit axiomatic statement of the foundations upon which one hoped to build without fear of further charges of inconsistency. Moreover, although Zermelo's system could avoid the somewhat inconsequential, but nevertheless serious, defects of Euclid's *Elements*, it is probably correct to assume that, like the Greek system, Zermelo's had only one model in mind, namely, a portion of set theory sufficient for ordinary mathematical purposes, yet carefully limited to avoid the known contradictions.

One should also recall, in this connection, the work of the 19th and early 20th

century pioneers in what is now usually called "Mathematical Logic." Here again the role of the axiomatic method as a mode of foundation was called into play. Even though Russell called his axioms "universally true," or tautological, they were clearly postulational and had later to be augmented by "multiplicative axioms" (axioms of choice) and "axioms of infinity" which could hardly be regarded as other than strictly axiomatic in nature. It is interesting to note that Russell, like Euclid and Zermelo, had only one model in mind, and he aimed at making the conditions surrounding his system so stringent that there could be only one model. In the first edition of his *Introduction to Mathematical Philosophy* he stated, "Logic is concerned with the real world just as truly as zoology, though with its more abstract and general features." The trouble with this (as perhaps Russell himself later concluded, since the statement is omitted in the later edition) is that while the model which zoologists study is already existent, that which Russell was studying was only an abstraction in process of evolution.

We note, too, that Russell and Whitehead were largely motivated by the desire to meet the crisis in the foundations caused by the set-theoretic contradictions. This was in contrast to logicians such as Peano and Frege who preceded them and who furnished a basis upon which they could proceed to build mathematics. Also, we should note the contrast between the axiomatic systems of Zermelo and of Russell and Whitehead in regard to the language used. Zermelo's was in the tradition of Euclid, as modernized by the 19th century mathematicians; primitive terms "set" and a relation between sets, "is an element of," were employed along with the natural language. Russell and Whitehead held a much grander conception, namely a foundation of the whole of mathematics, starting with what they termed primitive logical truths.

As it turned out, both systems exhibited deficiencies which had to be remedied. In Zermelo's case, the notion of "property" crept in under the guise of the natural language used, and since "property" and "set" were soon recognized to be virtually synonymous, it was necessary to substitute a more precise notion while at the same time eliminating the vicious circle—a task assumed by Fraenkel [3] and Skolem [12]. In the case of Russell and Whitehead's *Principia Mathematica*, aside from criticisms of the Reducibility Axiom, Axioms of Choice and the like (which elicited the question of just how far one can stretch the concept of "primitive logical truth"), the syntactical rules were deficient. This deficiency was remedied by those successors of Russell and Whitehead who adopted the formalist philosophy and, following the initial impulse given by Hilbert, made a clear separation between the primitive terms and axioms and the metamathematical rules for derivations of formulas (i.e., proving of theorems) from the axioms. Using our prerogative of hindsight, we can see that the two streams (that continued by Zermelo in the tradition of Euclid, and that started by Russell in the tradition of the symbolic logic of Boole and Frege) were heading for confluence.

An indication of this can be found in the historically important paper of Skolem given at the 5th Scandinavian Congress in 1922 [12]. Skolem, a logician

well acquainted with the logical system of Schröder, pointed out that the Zermelo axioms could be formulated as elementary statements within the framework of the Schröder logic, and that as a consequence the indefinite notion of "property" used by Zermelo could be adequately replaced by finite expressions formed from the "ϵ" and "$=$" relations. More important yet, he pointed out that a theorem proved by Löwenheim in 1915, concerning the Schröder algebra, could be simplified and adapted to show that if the Zermelo system is consistent, then its formulas must have *countable* models. Since formulas asserting the existence of powers higher than aleph-null can be proved in the Zermelo system, Skolem rightly concluded that "The axiomatic foundation of the theory of sets leads to a relativity of the set notion, and this is inseparably connected with every axiomatization." In his conclusion, he made clear that he did not believe the axiomatic method the proper tool to employ for a *foundation* of set theory—indeed, he expressed astonishment that so many mathematicians had so considered it.

Fortunately such a pessimistic attitude did not deter later investigators from continuing to apply axiomatics to set theory, even though the correctness of Skolem's conclusions was recognized. Von Neumann, for example, whose classical papers on axiomatic set theory were published soon after, remarked that the methods of Löwenheim and Skolem were applicable to his own system and that they consequently placed upon his, and every other axiomatic theory of sets, "the stamp of unreality." And after remarking that "it appears—that no categorical axiomatization of the theory of sets exists," he went on to state: "Since there exists no axiom system for mathematics, geometry, etc., which does not assume the theory of sets, so will there certainly be given no categorical axiomatic infinite systems. This circumstance" he continued, "appears to me to be an argument for intuitionism" [8]. In his general conclusions, then, von Neumann agreed with Skolem.

Undaunted, however, the "axiomatikers" continued where von Neumann left off, and in a series of papers beginning in 1937, Paul Bernays presented an effective and usable simplification of the von Neumann system. Although couched in the natural language, the system is clearly formalizable in the first-order predicate calculus; and about 1940 Gödel used it, with modifications, to establish the consistency of the axiom of choice and Cantor's generalized continuum hypothesis with the other axioms of set theory [5].

Now, aside from its strictly mathematical significance, this result was of prime importance from the standpoint of the evolution of the axiomatic method. In order to maintain this assertion, we must fill in one or two points that we have omitted in our historical survey.

I remarked earlier on the role of the axiomatic method in the increasing abstraction of mathematics. Parallel with this, during the latter part of the 19th century, the researches of Dedekind, Weierstrass, Cantor and others on the structure of the real number continuum were forcing set-theoretical ideas on the mathematical community—an example of what I earlier termed "hereditary"

stress. And although Cantor was astute enough to discover the so-called "continuum hypothesis," he never noticed that even in his first paper, in which he had to prove that every infinite set contains a set of cardinality aleph-null, he was using the axiom of choice. Peano noticed the choice principle (and objected to it) as early as 1890 [9], but the proof of the well-ordering theorem (published in 1904 by Zermelo [13]), was required to startle the mathematical community with the power of the axiom of choice.

This was a most important event from the standpoint of the evolution of mathematics, as well as a prime example of discovery and explicit formulation of a basic, hitherto unnoticed feature of a current concept. The continuum hypothesis, by way of contrast, was a natural derivation from the continuum *problem*; once the real numbers were shown to form a totality of power higher than aleph-null, one was immediately forced to ask whether it is the *next* higher power. Cantor mentions it in his 1883 paper in *Mathematische Annalen*, (vol. 21), and his first reaction was to state that he hoped soon to be able to prove that the cardinality c is the same as that of the second number-class. However one went on, naively, using the choice principle without ever recognizing its existence. Hilbert stated the continuum problem as the first of the famous set of problems which he gave at the 1900 Congress [6], and did not notice that he was assuming that every infinite set has a subset of cardinality aleph-null—which is, as we have already remarked, dependent on the choice principle. One had to wait for the most striking use of the principle, in the proof of the well-ordering theorem by Zermelo, to force general perception of its existence. It makes us wonder just how many other fundamental assumptions we are habitually making in our conceptual thinking, without either discovering them or giving them precise formulation.

Once the power and fundamental character of the principle was evident, Zermelo included it in his set of axioms for set theory [14]. On the other hand, he did not include the continuum hypothesis as an axiom, and thus was left open the question whether it could be proved from the other axioms for set theory.

For our purposes, the importance of Gödel's 1940 result, namely the consistency of the choice principle and continuum hypothesis with the parts of set theory that express generally recognized set-theoretic principles, is that it also showed the power of the axiomatic method as a mode for investigating and establishing relationships between various aspects of a theory. No matter whether one feels, as Skolem did, that set theory should not be axiomatized, one is impressed with Gödel's accomplishment. Many (including Gödel) were of the opinion that as a principle of general set theory, the continuum hypothesis is false; and that this might ultimately be deduced from generally accepted set-theoretic principles. Now one knew that this was a vain hope; and this was an accomplishment of the axiomatic method. One can still maintain that axiomatization is not the proper way to *formulate*, i.e., *found* set theory, while admitting that, as a tool for investigating the relationships between the various aspects of

that theory, and perhaps discovering new aspects, it has a legitimate role. Of course, the recent results of Paul Cohen [2], showing that *denials* of either choice axiom or continuum hypothesis are also consistent with the usual principles of set theory, have strengthened this thesis.

I have emphasized the type of role played by the axiomatic method in the evolution of set theory, because I think it is destined to receive more emphasis in the future. For centuries, mathematics got along with very imprecise conceptual tools. Except for the level of their achievements due to the centuries' accumulation of mathematical materials, the mathematicians of the pre-modern era were not on much surer ground than the ancient Babylonian number scientists. Can one imagine, however, an "outsider" such as Bishop Berkeley making valid criticisms of the basic concepts of mathematics today? Also, let us reflect for a moment that it is less than 100 years since mathematicians devised what has since been considered a precise formulation of the structure of the real number system—the real number continuum. At the time, this was considered an achievement of the highest order; the vaguely conceived notion of the "continuous" had at last been examined in its totality and seemingly described with precision. In Russell's words, "Whether or not the kind of series which Cantor defines as continuous is thought to be the most similar to what has hitherto been vaguely denoted by the word, the definition itself, and the steps leading to it, must be acknowledged to be a triumph of analysis and generalization" [11, p. 303]. Unfortunately, another vaguely conceived notion had been used in the process, that of "set." And this notion was so little suspect that even so competent and philosophically minded a mathematician as Poincaré could comment (albeit not ignoring the illusory nature of such beliefs among his forebears), "We believe that we no longer appeal to intuition in our reasoning." And, in analysis, he remarked "absolute rigor has been attained." (See Bell [1; 295].) Today, thanks to the axiomatic method, we know that Cantor, Dedekind, and all the rest of those 19th century pioneers only moved a step forward—an important step, to be sure. What they did was at least a further approximation. But so far as a precise formulation of the structure of the real number continuum is concerned, we know today that we still depend upon our intuition. Shall we accept the continuum hypothesis? Shall we declare all sets of real numbers measurable? In the present state of our mathematical intuition, we cannot answer these questions except by *edict*. But mathematical questions are not decided by edict. They are ultimately answered by hereditary stress and by other forces active in the evolution of mathematics. I surmise that in the future this will be one of the chief roles played by the axiomatic method: to help us analyze more deeply the consequences of what our intuitions suggest. Just as the demands of function theory forced a more precise analysis of the nature of the real number continuum, during the latter part of the last century, so probably will the demands of an increasingly abstract mathematics force decisions regarding such matters as the axiom of choice and the continuum hypothesis. As of now, I would not venture an opinion upon what the answer will be. Regarding the axiom of choice,

upon which the existence of nonmeasurable sets appears to depend, general acceptance seems highly probable. Too many intuitively necessary relations seem to depend upon it—for example, that if a set A is mapped upon a set B, then the number of elements in A is at least as great as the number of elements in B.

Let me repeat: I do not say that the axiomatic method is the proper way of founding either set theory or logic. Frankly, I am of the opinion that it is not. I do not believe that we should base mathematics upon variable systems of numbers, set theory, or logic—which is all that we can do with the axiomatic method at present. To this extent I am an intuitionist, and so far as can be told from their *behaviour*, so are most mathematicians. As working mathematicians, we use only one set theory, only one logic, and only one type of number system; and these are intuitively based, whether we admit it or not. Moreover, I believe that in contrast to the assumption that they are fully matured concepts—sort of "old-hat" ideas, as we might say—they are still in the process of evolution. I also believe that the role of the axiomatic method in this process will be fundamental. Up to now the axiomatic method has certainly shown itself to be the most important tool for the codification of what our intuitions tell us.

I do not wish to terminate these observations without mentioning what to many mathematicians are even more important roles of the axiomatic method. I should probably question the use of the definite article "the" in the expression "the axiomatic method"; because there seem to be several "axiomatic methods" in use today, as well as several ways of classifying them. There are roughly three types if we arrange them according to degree of formalization:

1. In what we might call the "Euclidean type," because of its similarity to Euclid's *Elements*, the primitive terms are not treated as undefined and only one model is described. The model is usually a concept suggested by our perceptions of the physical or social world, and the purpose is to set forth the fundamental properties and relations of the model. It is not the more refined type that we mathematicians commonly use, and is to be found mostly in studies of the physical and social science areas, where it seems to serve a useful function. Indeed, one can question whether in these areas (with the possible exception of certain physical theories) the types of axiomatics used in mathematics would yield significant results.

Interesting problems can be found in the application of this type of axiomatics, especially in regard to choice of models. The 17th and 18th centuries offer numerous examples of both the use and the misuse of the method; the best known are, I suppose, Spinoza's *Ethics* and Newton's *Principia*. The misuses of the method during this period may have had something to do with the virtual lapse in its application to the social sciences until recent times.

I am confident, nevertheless, that close study of that period would show relations to the emergence of symbolic logic. For example, Descartes and Hobbes both proposed what they called a "geometrization"—meaning an axiomatization

in the Euclidean manner—of all knowledge. In Descartes' case this included both medicine and ethics, and in Hobbes' case the proposal was to include psychology, ethics and politics. In both cases, a "universal calculus of reasoning" was plainly conceived. Much later, when Leibniz came upon the scene, the same kind of project was clearly in the air. Leibniz even attempted to apply the axiomatic method to politics. For instance, in 1669, when he was 23 years old and had studied both philosophy and law, he was in the service of the elector of Mainz and at this time the crown of Poland became vacant. It therefore fell to his lot to support the claims of his patron. For this purpose he wrote a little book, *Specimen demonstrationum politicarum pro rege Polonarum eligendo*, giving, in the "geometrical" manner, some sixty propositions (along with corollaries), demonstrating that three of the candidates merited exclusion while the fourth should be elected. (N.B. The fourth was not elected.) Two years later, using another "geometrical" system, he tried to convince Louis XIV that the French king should send troops against the Turks.

One can conjecture that examples such as these, along with Leibniz' companion ideas regarding a "calculus of reasoning," are among the ancestors of what later evolved into Mathematical Logic. There were many such examples, written by lesser lights (Leibniz' own teacher, Erhard Wiegel, a mathematician of repute at the University of Jena, wrote both on *Ethica Euclidea* and an *Idea Matheseos Universae*). Their lack of success in accomplishing their immediate objectives (due partially, no doubt, to the primitive conception of the axiomatic method then prevailing), should not obscure their significance in the evolution of human thought.

Probably most of us have seen attempts, that seemed only pretentious and ineffectual, at applying mathematical methods in areas that were previously purely descriptive or classificatory. However, I am confident that the axiomatic method of the "Euclidean type" does have a function in many such cases, especially of clarification and revelation of unnoticed properties—a function which the more refined type of axiomatics served, within mathematics itself, during the first part of the present century.

I think that the modern lack of success of the axiomatic method in the social sciences is probably due to two causes: (1) The notorious lack of theory in these sciences, and (2) the lack of adequately structured models (a deficiency probably caused by failure to perceive or sense certain important details of social patterns). The situation is somewhat analogous to that in set theory. In the area of physical reality, we perceived collections long before they had any mathematical significance; this is attested to by the fact that the words "class," "collection," and terms for special collections such as "flock," "herd," and "covey" were in the natural language long before mathematicians noticed that this aspect of reality is of vital importance. After Cantor's work established the importance of the notion of set, our intuitions of set theory developed to the point where a consistent model seemed to have been achieved; but today, nearly a century

later, we still have no unique or precisely clear model for set theory. Returning to the role of the axiomatic method in the social sciences, we notice an analogous situation today in both sociology and anthropology, where the concept of *culture* has had a history similar to that of set theory, except that it is still in the strictly intuitive state; it has not yet had the benefit of an analysis such as set theory has undergone.

The reason why the Greeks—and this applies also to the mathematicians of the 16th, 17th, 18th and 19th centuries—did not run astray in their reasoning is that they had developed a mature intuitive model for what they fancied to be physical reality. I do not wish to get too deeply involved in these matters, but what Euclid and later mathematicians were describing was not physical reality; it was a mental model which their perception of physical reality had suggested. And when we wonder at their not running into logical difficulties, we should recall that both the model and the logic they used were derived from this reality. It is interesting to observe that the first event of importance in axiomatic theory after the discovery of the non-euclidean geometries was the finding of models for the new theories. Thus, after venturing into what might have seemed domains of fantasy, one sought solace again in "reality"—at least within a structure, namely orthodox euclidean geometry, whose foundation was a conceptual model of certain aspects of physical reality. Moreover, in proposing the use of models as a test for logical consistency, the mathematician was only following the same path. Today, the theory of models in mathematical logic is a mature doctrine; but originally the use of models was only an appeal to reality, and the belief that reality is *consistent* was matched by the belief that only consistent theories are real—both Poincaré and Hilbert agreed upon this.

So far as mathematical theory is concerned, the "euclidean type" of axiomatics may now be dead, after having played an important role in the evolution of mathematical thought. But it will probably continue to play an important role in those areas of intellectual effort which do not have the venerable antiquity of older sciences such as mathematics.

2. The second type of axiomatics, according to my classification, is the one with which we are all familiar both in our research and in our teaching; it is the type used by the so-called "working mathematician"—a phrase I would rather not use in this connection, since I certainly consider my colleagues in mathematical logic to be working mathematicians—without quotation marks. We are careful to list our primitive terms, but we list neither the logical nor the set-theoretic rules by which we shall abide; hence the term "naive axiomatics." Tôward these latter, i.e. the logical and set-theoretic rules, we take what is operationally like an "absolute," or "Platonic" point of view. We know this method as a principal tool for modern research in all branches of mathematics, especially algebra, topology and analysis, and it is unnecessary to recite here the details of its important role; as I remarked earlier, it is responsible to a great extent for the increasing abstraction of modern mathematics.

The method also plays an increasingly important didactic role. I think a fairly straight line could be traced from the activities of the E. H. Moore school of mathematics at the University of Chicago during the first two decades of the century, down to what some call "the new school mathematics." One of the "products" of the E. H. Moore school was R. L. Moore, and most of us have heard of the "Moore method" of teaching—for those who haven't, an opportunity to hear it described by its chief exponent will be furnished by one of the films now being produced by the Committee on Educational Media under auspices of the Mathematical Association of America. Axiomatics is at the heart of this method. Incidentally, if E. H. Moore were alive today, he would certainly be active in the so-called "reforms" of elementary and secondary teaching, since he was much interested in teaching methods on these levels. Although I have never participated in writing the texts that are being produced for use in the elementary schools today, I get the impression that the axiomatic method, in the form of one of the first two types, is being employed to some extent. I have encountered not only young students who can quote to me the commutative and associative laws, but also some who talk set-theoretic language!

However, I have mixed feelings about the use of the axiomatic method for setting up the natural and real number systems. When I was a young instructor, I did not care for the method then prevailing in the theory of real functions, of starting with the Peano axioms; but I think my reaction was based largely on intuitive grounds. As I look back, I think that I was probably a semi-intuitionist, in that I felt the students had spent years using the arithmetic of natural and rational numbers, and that it was a waste of time giving it an axiomatic basis. Conversely, for the real number system, I felt that the students came to us in function theory with only the same understanding and familiarity with real numbers that a mature mathematician of a century ago had; and that here it was necessary to acquaint them with the structural theories of Dedekind and Cantor. Subsequent developments have provided, I think, valid arguments in support of this attitude. Moreover, I have the same feeling in regard to set theory. Sets, like natural numbers, have a natural background in our social, scientific and physical environment, and I believe that we can save considerable time in our curriculum if we proceed with the so-called "naive" approach. The *intuitive* comprehension of sets and their elementary properties should be built up first. Of course, as in the case of the natural numbers, once the student has developed an intuitive understanding of set theory, he can profit from seeing how a set theory and a theory of natural numbers based thereon can be set up using an axiomatic approach. But he should be aware that here the axiomatic method plays only a clarifying and investigative role; that so far as a *foundation* for the natural numbers, the real numbers, or set theory is concerned, only a relative characterization is achieved. Let me emphasize that I am referring here to the *pedagogical* role of the axiomatic method. I hope I have already made it clear that I approve heartily of its role in the *study of the foundations* of set

theory, where it serves to pinpoint aspects of our intuition that we would not otherwise recognize. The intuitive conceptions of the structure of the real number system prevalent 200 years ago may have been adequate for the mathematics of the time, but during the succeeding century its inadequacy became more and more apparent and provided the motivation for the more precise formulations by the axiomatic method; and with these formulations we have managed until the present day. Whether this will continue to be the case remains to be seen. At any rate, there can be no question regarding the importance of the role which the axiomatic method has played here. Nevertheless, we should distinguish between the uses to which the method is to be put. I do not question that the precise formulations of the laws of arithmetic may form a useful and clarifying function for the elementary schools, answering for the student some of the questions which the intuitive approach must raise; but they should follow, not precede the latter.

3. The third type of axiomatics, in which the logical apparatus not only enters the discussion, but is explicitly formalized, has proved one of the major tools in modern foundational research. Using an axiomatized functional calculus in which to imbed the technical structure of the theory, Tarski, Henkin, and others cleared up such matters as the relationship of consistency and models and the relation of completeness with models. We know now why a system such as the Peano axioms can be categorical when the set theory involved is not axiomatized, and why it is not categorical when it is axiomatized; and we shall have to rely upon future researches in mathematical logic to answer unsettled questions on set theory and on the real number continuum.

For example, Gödel's proof of the compatibility of the generalized continuum hypothesis with the other axioms of set theory was based on the notion of "constructible" sets; if we use the axiom requiring all sets to be constructible, the generalized continuum hypothesis holds. But we know now, from Paul Cohen's work, that the generalized continuum hypothesis is a weaker axiom itself than the axiom of constructibility. Of course, one may get all that is desired by simply adding the generalized continuum hypothesis to the axioms of set theory, but there are two objections to this: (1) it lacks the intuitive character associated with the other axioms of set theory, and (2) it lacks motivation in that its mathematical fruitfulness, up to now, is too meager.

In summary, as I consider the three types of axiomatics that I have arbitrarily marked off, I sense that modern mathematics, despite its abstractness, looks more and more like an applied science. When the applied scientist uses the Euclidean type of axiomatics to analyze and describe a conceptual model in a physical or social situation, he is deriving his axioms from a perceptually induced concept. When the so-called "working mathematician" uses the "naive" method, he is deriving his axioms from an intuitively induced concept—from what his *mathematical* intuition has sensed to be an important structure or pattern. The purest form of the axiomatic method, type 3, has enabled the logician

to analyze our logical methods and our set theory—matters taken for granted in "naive" axiomatics. Also, the creative role which axiomatics has played on the second level is paralleled by its more fundamental creative role in the use of type 3, in which our most basic intuitions are strengthened and clarified by the discovery of new axioms as, e.g., the axiom of constructibility of Gödel.

Despite its limitations, and despite its failure to provide the type of foundation originally conceived by Peano, Hilbert and other pioneers, the axiomatic method is not yet at the end of its hey-day—perhaps its greatest glory is even yet to come. Its expanding role in pedagogy, as a research tool for the analysis of abstract mathematical structures and in the investigation of the methods and structures offered by our intuitions, are perhaps only a harbinger of more fundamental roles to come. Although the axiomatic method seemingly cannot fill the role of providing an intuition-free foundation for mathematics, I think it will continue to be one of our most effective tools for the creation of new mathematics and the teaching of mathematics.

This is a slightly revised version of an address delivered before sectional meetings of the Association during the spring of 1965.

VECTORIAL INVERSIVE AND NON-EUCLIDEAN GEOMETRY

H. W. ALEXANDER, Earlham College (Now at University College, Nairobi, Kenya)

The purpose of this paper is to show how vectorial methods, familiar from linear algebra, may be used to provide an analytic treatment of inversive and non-Euclidean geometry. As an application of the central ideas of linear algebra, this type of analytic geometry is quite different in flavor from the familiar vectorial treatments of affine and Euclidean geometry. As against the usual inner product of vectors, this geometry employs a type of "inner product" of a pair of vectors which arises as naturally in the context of the geometry of circles as does the familiar inner product in the context of Euclidean geometry. The tools are developed for an extensive preliminary exploration of the very rich geometry of circles and spheres, which tends to be neglected in the modern curriculum.

Let (x_1, x_2) be a point in a Cartesian plane. Consider the equation

$$a_0(x_1^2 + x_2^2) - 2a_1x_1 - 2a_2x_2 - 2a_3 = 0, \quad a_i \text{ real.} \tag{1}$$

If $a_0=0$, $a_1^2+a_2^2\neq 0$, then (1) corresponds to a straight line. If $a_0\neq 0$, then (1) corresponds to a circle with center $(a_1/a_0, a_2/a_0)$ and radius

$$r_A = \frac{1}{|a_0|}(a_1^2 + a_2^2 + 2a_0a_3)^{1/2}. \tag{2}$$

Thus the circle will be real, null or imaginary according as $a_1^2+a_2^2+2a_0a_3$ is positive, zero or negative.

The key idea we wish to introduce is that of associating a 4-dimensional vector $A=(a_0, a_1, a_2, a_3)$ with the equation (1), and with the corresponding locus. Let $A=(a_0, a_1, a_2, a_3)$, $B=(b_0, b_1, b_2, b_3)$ be two vectors. We define a type of inner product, which we shall call the "number product" of A and B, denoted by $A\#B$, as follows:

$$A \# B = a_1b_1 + a_2b_2 + a_0b_3 + a_3b_0. \tag{3}$$

In particular,

$$A \# A = a_1^2 + a_2^2 + 2a_0a_3, \tag{4}$$

so that if A corresponds to a circle, its radius is, from (2),

$$r_A = \frac{1}{|a_0|}(A \# A)^{1/2}. \tag{5}$$

It is readily verified that the number product has the following properties:

$$A \# (B + C) = A \# B + A \# C; \quad (aA) \# B = a(A \# B); \quad A \# B = B \# A. \tag{6}$$

Let us now agree to use the term "stircle" to mean either a straight line or a circle, and let us speak of "the stircle A" to mean the stircle corresponding to the 4-vector A and to any nonzero multiple of A. We exclude from all consideration the vector (0, 0, 0, 0), which corresponds to no locus.

It is convenient to say that two vectors are *equivalent* if one is a nonzero scalar multiple of the other. With this understanding, there corresponds to a given stircle an *equivalence class* of vectors, which may be denoted by $\langle A \rangle$, where A is any member of the class. If the vectors A and B both correspond to the same stircle, then we may write either $A = kB$, or better $\langle A \rangle = \langle B \rangle$. The equation $A = B$ means, as it usually does, that the two 4-vectors are equal; that is, $a_i = b_i$, $i = 0, 1, 2, 3$. Every such equation occurring in this paper may, however, also be interpreted as stating that the stircle A is identical with the stircle B, and thus that $\langle A \rangle = \langle B \rangle$.

Suppose that A and B are both circles, so that $a_0 \neq 0$, $b_0 \neq 0$. Let d be the distance between the centers. Then it is readily shown that

$$d^2 = r_A^2 + r_B^2 - 2(A \# B)/a_0 b_0. \tag{7}$$

The condition of orthogonality of circles A and B is $d^2 = r_A^2 + r_B^2$, which in view of (7) reduces to

$$A \# B = 0. \tag{8}$$

It is readily verified that (8) is still the condition of orthogonality when either A, or B, or both, are straight lines. Thus (8) is the condition of orthogonality of any pair of stircles.

Suppose P is a null circle (or point circle). Then $P \# P = 0$. For convenience, since $p_0 \neq 0$, put $p_0 = 1$. Then from $P \# P = 0$ we deduce that $p_3 = -\frac{1}{2}(p_1^2 + p_2^2)$, so that a point may always be written in the form

$$P = (1, p_1, p_2, -\tfrac{1}{2}(p_1^2 + p_2^2)). \tag{9}$$

The orthogonality condition $A \# P = 0$ now becomes $-\frac{1}{2}a_0(p_1^2 + p_2^2) + a_1 p_1 + a_2 p_2 + a_3 = 0$; and this, from (1), is the condition that (p_1, p_2) shall lie on the stircle A. In fact,

$$A \# X = 0 \tag{10}$$

is seen to be a compact way of writing (1), provided $X \# X = 0$.

Suppose A and B are real circles. Let us make the definition

$$\Delta(A, B) = (A \# A)(B \# B) - (A \# B)^2. \tag{11}$$

Let us use (5) and (7) to eliminate $A \# A$, $B \# B$ and $A \# B$ from the right of (11). With a little algebra we find

$$\Delta(A, B) = \frac{a_0 b_0}{4}(r_A + r_B + d)(r_A + r_B - d)(r_A + d - r_B)(r_B + d - r_A). \tag{12}$$

If A, B intersect in two points, then their centers together with either point of intersection form a triangle with sides d, r_A, r_B, and (12) then shows that $\Delta(A, B)$ will be positive. If A, B are tangent, then (12) shows that $\Delta(A, B) = 0$; while if A, B have no common points, then $\Delta(A, B)$ will be negative.

Suppose A, B intersect, and θ is the angle between the radii from the two centers to either point of intersection. Then from the law of cosines it is easily established that

$$\cos\theta = (A \# B)\left[(A \# A)(B \# B)\right]^{-1/2}. \tag{13}$$

The angle θ may also be regarded as the angle between A and B. The formula continues to hold good when either, or both, of the stircles A, B become straight lines.

Let A and B be distinct stircles; this means that the vectors A and B are linearly independent. We shall use the notation $\langle A, B\rangle$ for the set of all stircles linearly dependent on A and B. That is,

$$\langle A, B\rangle = \left\{C \mid C = aA + bB,\ a, b \text{ real},\ a^2 + b^2 \neq 0\right\}. \tag{14}$$

The system of stircles so defined is called a *pencil* of stircles. In the older literature such a set is called a *coaxal system* of circles, and the straight line belonging to the pencil is called its *radical axis*. More explicitly, we shall call $\langle A, B\rangle$ the pencil based on A, B. We now distinguish three cases according to whether A, B intersect, are tangent, or have no common points.

(a) $\Delta(A, B) > 0$. Let P be one of the points of intersection of A and B. Then from (1), $P\#A = 0$, $P\#B = 0$. Hence $P\#(aA+bB) = 0$, and we conclude that every stircle of the pencil goes through both points of intersection of A and B. A pencil of this type is called *elliptic*.

(b) $\Delta(A, B) = 0$. Then a little algebra shows $\Delta(A, aA+bB) = 0$. The consequence is that all the stircles of the pencil are mutually tangent at a single point. This type of pencil is called *parabolic*.

(c) $\Delta(A, B) < 0$. Let us ask whether the pencil contains one or more null circles. We find $(aA+bB)\#(aA+bB) = a^2A\#A + 2abA\#B + b^2B\#B$. Under what circumstances will there exist a ratio a/b which will make this expression vanish? If $\Delta(A, B) < 0$ there are two such ratios. Thus the pencil contains two points. Such a pencil is called *hyperbolic*. Note that in the case of a parabolic pencil there is just one point. An elliptic pencil contains no points.

It is a rather simple exercise to show that the centers of all the circles in a pencil lie on a straight line, and that every pencil contains just one straight line, unless both A and B are straight lines, in which case we have a pencil of straight lines.

Suppose we have two pencils $\langle A, B\rangle$ and $\langle C, D\rangle$ such that $A\#C = 0$, $A\#D = 0$, $B\#C = 0$, $B\#D = 0$. It is then readily verified that every member of $\langle A, B\rangle$ will be orthogonal to every member of $\langle C, D\rangle$. Under such circumstances we say that the pencils $\langle A, B\rangle$ and $\langle C, D\rangle$ are mutually orthogonal. Let P, Q be points, and R, S two stircles passing through P, Q. Then $\langle P, Q\rangle$ is a hyperbolic pencil, and $\langle R, S\rangle$ is an elliptic pencil orthogonal to $\langle P, Q\rangle$.

Suppose that A, B, C are linearly independent vectors, so that the corresponding stircles do not belong to the same pencil. The *bundle* of stircles based on A, B, C, denoted by $\langle A, B, C\rangle$, is defined to be the set of all stircles linearly

dependent on A, B, C:

$$\langle A, B, C\rangle = \{X \mid X = aA + bB + cC;\ a, b, c \text{ real},\ a^2 + b^2 + c^2 \neq 0\}. \tag{15}$$

Elementary linear algebra tells us that there is a vector D, unique to within a multiplied constant, which is such that $A\#D=0$, $B\#D=0$, $C\#D=0$. It then follows that $X\#D=0$, where $X=aA+bB+cC$, so that D is orthogonal to every stircle of the bundle. Thus $\langle A, B, C\rangle$ may be described as the set of all stircles orthogonal to D. If D is real, we have a *hyperbolic* bundle; if D is a point, we have a *parabolic* bundle; if D is imaginary, we have an *elliptic* bundle. Note that a parabolic bundle consists of all stircles passing through a point. It may also be shown that an elliptic bundle consists of all stircles which cut a fixed circle E at the extremities of a diameter of E. The circle E is known as the *equator* of the bundle.

Suppose A is a real stircle, and P is a point not on A, so that $P\#A\neq 0$. The pencil $\langle A, P\rangle$ is hyperbolic, since P and A are not incident. One of its null circles is P. The other, which we shall denote by P_A, is called the *inverse of P relative to A*. To find it explicitly, write $X=aA+pP$ for the general member of $\langle A, P\rangle$. We then find $X\#X=a^2A\#A+2apA\#P$; we have used the fact that $P\#P=0$. In order that X may be a point, we must either have $a=0$, in which case X is identical with P; or $a=-2p(A\#P)/(A\#A)$. In the latter case,

$$X = p\left[P - 2\frac{A\#P}{A\#A}A\right].$$

It is convenient to put $p=1$, and define P_A by means of

$$P_A = P - 2\left(\frac{A\#P}{A\#A}\right)A. \tag{16}$$

This is our fundamental formula for inversion. We shall consider it as defining the inverse of P relative to A, even when A is an imaginary circle. Note that (16) is meaningless if A is a point. It is readily shown that P is also the inverse of P_A relative to A. Since the centers of all the circles belonging to a pencil are collinear, it follows that if A is a circle, then P, P_A and the center of A are collinear.

Consider two stircles A and B. The inverse of B relative to A, denoted by B_A, is defined to be the set of points which are inverses, relative to A, of points lying on B. We shall show that B_A is given by essentially the same formula (16) as was obtained for the inverse of a point P relative to A:

$$B_A = B - 2\left(\frac{A\#B}{A\#A}\right)A. \tag{17}$$

Preparatory to showing this, let C be a second stircle, and define

$$C_A = C - 2\left(\frac{A\#C}{A\#A}\right)A.$$

Now form, and evaluate, the number product $B_A \# C_A$; it is readily found that

$$B_A \# C_A = B \# C. \tag{18}$$

Now let P_A be the inverse of P relative to A, defined by (16), and let B_A be defined by (17). Then, using (18), $P_A \# B_A = P \# B$. Thus P_A is incident with B_A if and only if P is incident with B. We conclude that B_A is actually the set of inverses, relative to A, of all points lying on B.

Let $C=(1, c_1, c_2, c_3)$ be a circle which is not null, so that $c_3 \neq -\frac{1}{2}(c_1^2+c_2^2)$. Its center is $P=(1, c_1, c_2, c_3^*)$, $c_3^* = -\frac{1}{2}(c_1^2+c_2^2)$. We readily find $C \# C = 2C \# P$. If we now use (16) to find the inverse of P relative to C, we obtain $P_C = P - C = (0, 0, 0, c_3^* - c_3)$. Thus the "inverse" vector is of the form $(0, 0, 0, a)$, $a \neq 0$, which corresponds to no point, straight line or circle, real or imaginary. In order to provide every point with an inverse relative to every stircle we associate $(0, 0, 0, 1)$ with an "ideal" stircle, which may be called the "stircle at infinity" or the "point of infinity." The set of points of the Euclidean plane, with $(0, 0, 0, 1)$ adjoined, is called the *inversive plane*. In this plane, every stircle possesses an inverse relative to every other stircle.

Inversive geometry may be defined to consist of the collection of definitions and theorems expressing properties which are preserved under inversion. For example, consider the following theorem of inversive geometry: let A, B, A' be such that A and A' are mutually inverse relative to B. Let C be another stircle, and let A_C, B_C, A'_C be the inverses of A, B, A' relative to C. Then A_C and A'_C are mutually inverse relative to B_C. Using (13) and (18) we may show that the angle between two stircles is preserved under inversion. We thus say that inversion is a *conformal* transformation.

Let us briefly indicate how these ideas may be extended to three dimensions. The extension to n dimensions is then rather straightforward. An attractive feature of this extension is that formulas (16) and (17) are unchanged. Let us begin by defining, for any pair of 5-vectors $A=(a_0, a_1, a_2, a_3, a_4)$ and $B=(b_0, b_1, b_2, b_3, b_4)$, the number product

$$A \# B = a_1b_1 + a_2b_2 + a_3b_3 + a_0b_4 + a_4b_0. \tag{19}$$

Thus we have

$$A \# A = a_1^2 + a_2^2 + a_3^2 + 2a_0a_4. \tag{20}$$

If (x_1, x_2, x_3) represents a point in Cartesian 3-space, then the equation

$$a_0(x_1^2 + x_2^2 + x_3^2) - 2a_1x_1 - 2a_2x_2 - 2a_3x_3 - a_4 = 0 \tag{21}$$

represents a sphere if $a_0 \neq 0$, with center $(a_1/a_0, a_2/a_0, a_3/a_0)$ and radius given by (5). If $a_0=0$, but $a_1^2+a_2^2+a_3^2 \neq 0$, then (21) represents a plane. We shall say, in general, that (21) corresponds to a *splane*, including both sphere and plane in this concocted term, and we shall associate with the splane (21) the vector $A=(a_0, a_1, a_2, a_3, a_4)$. The special case $(0, 0, 0, 0, a_4)$, $a_4 \neq 0$, we shall call the

point at infinity. When this special point is adjoined to Euclidean 3-space we obtain *inversive space.*

As in the 2-dimensional case, (8) is the condition of orthogonality of two splanes, and (10) is the condition of incidence of the point X and the splane A; (10) may be regarded as a compact version of (21). If A and B are intersecting splanes, their angle is given by (13). Pencils and bundles of splanes are defined by (14) and (15). If A, B, C, D are linearly independent (i.e., do not belong to the same bundle), then $\langle A, B, C, D\rangle$ will denote the *hyperbundle* defined by

$$(22)\quad \langle A, B, C, D\rangle = \{X \mid X = aA+bB+cC+dD;\ a, b, c, d \text{ real},\ a^2+\cdots+d^2\neq 0\}.$$

Suppose we have a point P and a real splane A. Then $\langle A, P\rangle$ is an elliptic pencil whose second null sphere (i.e., point) is P_A given by (16). We again call P_A the inverse of P relative to A. As in the earlier case, we may show that P, P_A and the center of A are collinear, provided A is a sphere. The more general formula (17) will again give the inverse of any splane B relative to any non-null splane A. It will again turn out that the angle between splanes is preserved under the inversion.

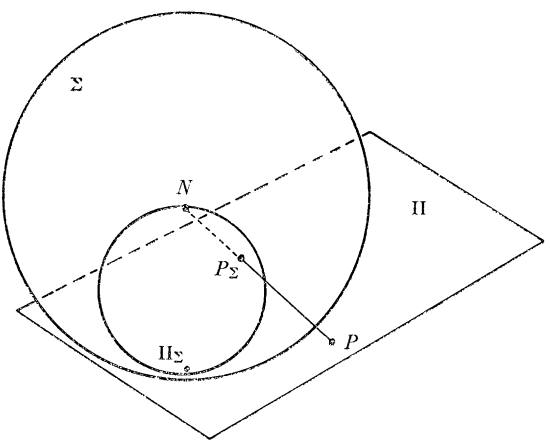

FIG. 1

We now consider an important specialization of inversion known as stereographic projection. In Figure 1, let Π be the plane $x_3=0$, which as a splane has the vector $\Pi=(0, 0, 0, 1, 0)$. Let Σ be the sphere which is tangent to Π at the origin, with center at N:(0, 0, 2), whose 5-vector is (1, 0, 0, 2, 0). According to (17), the inverse of Π relative to Σ is $\Pi_\Sigma=(1, 0, 0, 1, 0)$, which is a sphere tangent to Π at the origin, of unit radius. It is seen that Π_Σ passes through the center of Σ; in fact, if the origin is regarded as the "south pole" of Π_Σ then the center of Σ, namely N, is the "north pole" of Π_Σ. We know that if P is any point of Π, then its image P_Σ under the inversion will lie on Π_Σ; and furthermore, N, P and P_Σ will be collinear. Thus we have (as part of the inversion relative to Σ) a mapping

from Π onto Π_Σ in which corresponding points are collinear with N. Such a mapping is known as a stereographic projection from Π to Π_Σ. We shall use I as the symbol for the inversion relative to Σ. Thus P_Σ can be written $I(P)$, and we may also write $P=I(P_\Sigma)$.

We may now deduce easily that stereographic projection carries circles on Π_Σ into stircles on Π. For suppose that C is a circle on Π_Σ, and that Π^* is the plane in which C lies. Then we may write $C=\Pi^*\cap\Pi_\Sigma$. Its stereographic image is $I(\Pi^*)\cap I(\Pi_\Sigma)$. Hence $I(C)$ is the intersection of a splane $I(\Pi^*)$ and the plane $\Pi=I(\Pi_\Sigma)$; it is thus a stircle of Π.

Consider an elliptic pencil $\langle A, B\rangle$ on Π, whose stircles go through the distinct points P, Q. Its image under the inversion I is a set of circles on Π_Σ, which pass through the image points P_Σ, Q_Σ of P and Q. We can readily see that this set of circles is the intersection of the sphere Π_Σ and a pencil of planes which pass through the line joining P_Σ, Q_Σ. We call such a set an elliptic pencil of circles on Π_Σ. Similarly, a hyperbolic pencil on Π will be mapped into a hyperbolic pencil on Π_Σ, and the corresponding pencil of planes will either consist of mutually parallel planes, or of planes which pass through a line which does not cut Π_Σ.

Finally, a parabolic pencil in Π will map into a parabolic pencil on Π_Σ; and the line common to the corresponding pencil of planes will be tangent to Π_Σ.

Just as we have pencils of three types on the sphere Π_Σ, so we have bundles of three types on Π_Σ, each being the image of a bundle of the same type on Π. An elliptic bundle on Π_Σ possesses the important property that the set of planes of the circles of the bundle all pass through a common point P *which is interior to* Π_Σ. Thus if A and B are any two circles of this elliptic bundle their planes must intersect in a line which cuts Π_Σ in two points. Thus every pair of circles of an elliptic bundle must intersect. The same must be true of pairs of stircles belonging to an elliptic bundle of stircles in the plane Π. Hence, if B, C belong to an elliptic bundle, $\langle B, C\rangle$ is an elliptic pencil.

Example 1. Let E be the equator of Π_Σ, whose plane is parallel to Π and goes through the center C: (0, 0, 1) of Π_Σ. The image E_Σ of E will be a circle of radius 2 about the origin; its 4-vector is $E_\Sigma=(1, 0, 0, 2)$. Now consider the bundle of planes through C. A suitable basis for this bundle consists of the three planes (0, 1, 0, 0, 0), (0, 0, 1, 0, 0), (0, 0, 0, 1, -1). The inversion I carries these into the splanes (0, 1, 0, 0, 0), (0, 0, 1, 0, 0), (1, 0, 0, 0, 2), which cut Π in the stircles $L=(0, 1, 0, 0)$, $M=(0, 0, 1, 0)$, $E_\Sigma=(1, 0, 0, 2)$. These, then, form a basis for the bundle of stircles in the plane Π into which the great circles on Π_Σ are projected. We note two facts about this bundle. First, since the three stircles above listed are orthogonal to $A=(1, 0, 0, -2)$, the bundle must be orthogonal to A. This is, as it should be, an imaginary circle. Second, we note that the pencil $\langle L, M\rangle$ consists of all diameters of E_Σ. Thus the bundle $\langle L, M, E_\Sigma\rangle$, which we are considering, consists of all stircles in the plane Π which cut E_Σ in a pair of diametral points.

We shall now use the tools we have developed in order to investigate various forms of plane geometry. A "geometry" is here understood as a system involving

two sets $\mathcal{P}$ and $\mathcal{L}$ and an incidence relation. The set $\mathcal{P}$ consists of "points," the set $\mathcal{L}$ of "lines." A "point" P and a "line" L are said to be incident if P lies on L, or L goes through P.

On the sphere we have a natural geometry in which $\mathcal{P}$ consists of the points of the sphere, and $\mathcal{L}$ consists of its great circles which, as we have seen, form an elliptic bundle. This suggests that an interesting geometry on π may arise when we take for $\mathcal{L}$ the stircles of an elliptic bundle.

In Euclidean geometry the "lines" are the straight lines of the plane. Let us project these lines from Π to Π_Σ. They are projected into a parabolic bundle on Π_Σ, whose associated bundle of planes consists of all planes through the north pole N. This suggests that a parabolic bundle, on the plane Π or on the sphere Π_Σ, ought to give rise to an "interesting" geometry.

Motivated by these considerations, let us ask what kind of geometries arise when we take a bundle of stircles in the plane as the system of "lines," $\mathcal{L}$, of the geometry we are building. We know that all stircles of a bundle are orthogonal to a stircle, which is a real stircle, a point, or an imaginary circle according as the bundle is hyperbolic, parabolic or elliptic. This stircle we call the absolute, A, of the geometry; and we call the geometry hyperbolic, parabolic, or elliptic according as the bundle is hyperbolic, parabolic, or elliptic.

Hyperbolic geometry is, in fact, the type of non-Euclidean geometry which was investigated in the first quarter of the nineteenth century by Gauss, Bolyai and Lobachevski; it is often known as Lobachevskian geometry. Elliptic geometry was so named by Felix Klein, following suggestions made by Bernhard Riemann in his famous inaugural dissertation of 1854. The use of the terms elliptic, parabolic and hyperbolic as names for these geometries is due to Klein.

We have defined the set $\mathcal{L}$ consisting of the "lines" of the system of geometry. As a preliminary to our definition of the set $\mathcal{P}$, we note that two "lines" may have two common points. If the "lines" B and C, both orthogonal to the absolute A, have in common the points P and P', then every stircle of the elliptic pencil $\langle B, C\rangle$ will go through P and P', and it follows that P, P' and A belong to a hyperbolic pencil orthogonal to $\langle B, C\rangle$. If A itself does not reduce to a point (as it does in parabolic geometry) this means that P and P' are mutually inverse relative to A. Such a pair of points, $\{P, P'\}$, we shall call a "point" in our geometry, and $\mathcal{P}$ will consist of all possible point-pairs, each pair mutually inverse relative to A. We have now defined $\mathcal{P}$ in the elliptic and hyperbolic cases. In the parabolic case, we define $\mathcal{P}$ to consist of all point-pairs of the form $\{A, P\}$, where A is the absolute, and P is a point of the inversive plane. In all three cases, we define a "point" to be incident with a "line" if both points of the point-pair are on the stircle which represents the "line." We have now ensured that two "lines" will intersect in no more than one "point." In the case of elliptic geometry two "lines" will always have precisely one common "point." Thus elliptic geometry is a type of projective geometry.

It is often convenient to choose, from each point-pair, a single representative, and regard these representatives as the "points" of the geometry. In hyper-

bolic geometry A is real. If A is a circle we can take the Euclidean points interior to A as representatives; we then have the so-called Poincaré model of hyperbolic geometry. If A is a straight line, we may take the Euclidean points on one side of A as representatives; this is the half-plane model of hyperbolic geometry. If A is imaginary, and the geometry elliptic, we return to the viewpoint of Example 1, in which the great circles on the sphere were stereographically projected into the elliptic bundle orthogonal to $A=(1, 0, 0, -2)$. The southern hemisphere of Π_Σ is projected into the interior of the circle $E_\Sigma=(1, 0, 0, 2)$. It is convenient to take as a set of representatives of $\mathcal{P}$ the interior of E_Σ together with one-half of the points of E_Σ itself; for example, those on any open semi-circle of E_Σ, with one or other of the endpoints of the semi-circle.

In the case of parabolic geometry, the representative points will be the points of the inversive plane, except the point A itself.

We must now introduce a set of mappings which will be the analog of the rigid motions (isometries) of Euclidean geometry. It is reasonable to require that these mappings carry "lines" into "lines," and preserve "angle" and "length." Our strategy is to select a set of mappings which carry "lines" into "lines," and then define "angle" and "length" so as to remain invariant under these mappings. Let A be the absolute; let B be the bundle of stircles orthogonal to A which constitutes the set of "lines," and let M be any inversion. Under M, A and B are carried into $M(A)$ and $M(B)$, and the latter is a bundle orthogonal to the stircle $M(A)$. But is it the *same* bundle? Not unless $M(A)=A$. In view of this, we restrict ourselves to inversions which leave A fixed, and call these "reflections." Each "reflection" is an inversion relative to a "line" of the geometry. We may now define an "isometry" to be the composite of a finite sequence of "reflections."

Next, consider "angle" and "length." The first is easy to dispose of, since an inversion preserves the Euclidean angle between stircles. We accordingly define "angle" between "lines" to be the Euclidean angle between the corresponding stircles.

We can derive, without difficulty, a concept of "length" in the case of elliptic geometry, using as our starting point the arc length of a circle on the sphere, or, what amounts to the same thing, the angle between radii joining the center to two points on the sphere. In Example 1, a sphere Π_Σ was projected stereographically onto the plane Π from the north pole N. Let C:(0, 0, 1) be the center of Π_Σ. The stereographic projection is identical with the inversion I relative to the sphere $\Sigma=(1, 0, 0, 2, 0)$. Given two points P, Q of Π, we find their image points P_Σ, Q_Σ on Π_Σ, and we define the "distance" $d(P, Q)$ to be one-half of the smaller arc length along the great circle joining P_Σ, Q_Σ; if P_Σ, Q_Σ are antipodal, $d(P, Q)$ will be one quarter of the circumference of a great circle. In general, then, $d(P, Q)=\frac{1}{2}\angle P_\Sigma C Q_\Sigma$.

Let P, considered as a 5-vector, be

$$P = (1, p_1, p_2, 0, p_4), \quad p_4 = -\tfrac{1}{2}(p_1^2 + p_2^2).$$

Then we have $\Sigma\#\Sigma=4$, $\Sigma\#P=p_4$, so that

$$P_\Sigma = P - \tfrac{1}{2}p_4\Sigma = (1 - \tfrac{1}{2}p_4, p_1, p_2, -p_4, p_4).$$

This is a point on the sphere Π_Σ. As a point in 3-space its coordinates are $(\alpha p_1, \alpha p_2, -\alpha p_4)$, where $\alpha=(1-\frac{1}{2}p_4)^{-1}$. The space-vector $\overrightarrow{CP_\Sigma}$ is $(\alpha p_1, \alpha p_2, -\alpha p_4-1)$. Similarly the point $Q=(1, q_1, q_2, 0, q_4)$, where $q_4=-\frac{1}{2}(q_1^2+q_2^2)$ corresponds to the space-vector $\overrightarrow{CQ_\Sigma}=(\beta q_1, \beta q_2, -\beta q_4-1)$, where $\beta=(1-\frac{1}{2}q_4)^{-1}$. The vectors $\overrightarrow{CP_\Sigma}$ and $\overrightarrow{CQ_\Sigma}$ are unit vectors, since Π_Σ is of unit radius. Hence

$$\cos\angle P_\Sigma C Q_\Sigma = \overrightarrow{CP_\Sigma}\cdot\overrightarrow{CQ_\Sigma} = 1 + \alpha\beta(p_1q_1 + p_2q_2 + p_4 + q_4) = 1 + \alpha\beta(P\,\#\,Q).$$

Considered as stircles in the plane Π, $P=(1, p_1, p_2, p_4)$, $Q=(1, q_1, q_2, q_4)$, and $A=(1, 0, 0, -2)$. Hence we have $A\#P=p_4-2=-2\alpha^{-1}$, $A\#Q=-2\beta^{-1}$, and

$$\sin^2(d(P, Q)) = \sin^2\tfrac{1}{2}\angle P_\Sigma C Q_\Sigma = -\tfrac{1}{2}\alpha\beta(P\,\#\,Q) = \frac{-2(P\,\#\,Q)}{(A\,\#\,P)(A\,\#\,Q)}.$$

This is nonhomogeneous with respect to A; that is, if the vector A is multiplied by a nonzero scalar k, then $\sin^2(d(P, Q))$ will be multiplied by k^{-2}. To overcome this flaw, we introduce $A\#A=-4$ in the numerator, obtaining

$$d(P, Q) = \sin^{-1}\left[\frac{(A\,\#\,A)(P\,\#\,Q)}{2(A\,\#\,P)(A\,\#\,Q)}\right]^{1/2}. \tag{22}$$

This is our basic distance function in the elliptic case.

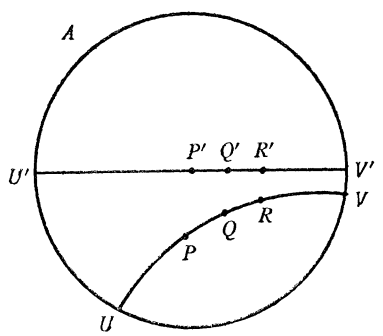

FIG. 2

In order to determine what form $d(P, Q)$ shall take in the hyperbolic case, let L be a "line" which meets the absolute A in the points U and V (see Figure 2). Let P, Q, R be three points of L, where Q is *between* P and R in the sense that if we traverse L from U to V we encounter first P, then Q, then R. We wish to show that the appropriate distance function, in this case, is

$$d(P, Q) = \sinh^{-1}\left[\frac{-(A \# A)(P \# Q)}{2(A \# P)(A \# Q)}\right]^{1/2}. \tag{23}$$

We may show, without difficulty, that a rigid motion (in fact, a sequence of no more than two reflections) exists which will carry P to the center of A, which we call P', and Q and R to the points Q' and R' on the positive x_1-axis, with Q' between P' and R'. Let

$$A=(1, 0, 0, a^2/2),\quad P'=(1, 0, 0, 0),\quad Q'=(1, q, 0, -q^2/2),\quad R'=(1, r, 0, -r^2/2),$$

where $0<q<r<a$.

It is reasonable to require that the distance function $d(P, Q)$, as in the elliptic case, be expressible in terms of the quantity $[(A\#A)(P\#Q)]/[2(A\#P)(A\#Q)]$. It turns out to be convenient to consider, not this quantity itself, but a function of it:

$$K(P, Q) = \sqrt{\frac{-(A \# A)(P \# Q)}{2(A \# P)(A \# Q)}} + \sqrt{1 - \frac{(A \# A)(P \# Q)}{2(A \# P)(A \# Q)}}. \tag{24}$$

Let us evaluate $K(P', Q')$, $K(P', R')$, $K(Q', R')$. We find

$$K(P', Q') = \sqrt{\frac{a+q}{a-q}},\quad K(P', R') = \sqrt{\frac{a+r}{a-r}},\quad K(Q', R') = \sqrt{\frac{(a+r)(a-q)}{(a-r)(a+q)}}.$$

From these expressions it is evident that

$$K(P', R') = K(P', Q')\cdot K(Q', R').$$

We thus have a multiplicative relationship between $K(P', R')$, $K(P', Q')$ and $K(Q', R')$; whereas we clearly want an *additive* relationship $d(P', R')=d(P', Q')+d(Q', R')$ to prevail between adjacent arcs on the same "line." To bring this about, we define $d(P, Q)=\log K(P, Q)$, and appeal to the formula $\sinh^{-1}x=\log(x+\sqrt{(1+x^2)})$. Thus we find, from (24), the desired distance function (23).

We are now in a position to derive the various properties of hyperbolic and elliptic geometry. Of these, we shall concern ourselves only with *parallelism* and the *angle sum of a triangle*. Given a line L and a point P not on L:

(25a) in *Euclidean geometry*, there is a unique line L' through P which does not meet L;

(25b) in *elliptic geometry*, there is no line through P which does not meet L;

(25c) in *hyperbolic geometry*, there are infinitely many lines through P which do not meet L.

(25a) is, of course, Euclid's fifth postulate in the Playfair form. We can show that this statement holds true, also, for any parabolic geometry. Given the "point" P and the "line" L, consider the parabolic pencil $\langle A, L\rangle$, where A is the absolute. There is a unique member, say L', of this pencil which passes through P. It has no "point" in common with L.

Proposition (25b) follows from the fact, mentioned earlier, that in an

elliptic bundle *every pair of stircles intersects.* To see that (25c) is true, consider the Poincaré model in which the absolute A is a real circle. The proof for the halfplane model would be quite similar. The "line" L will meet A in two points Q and R. Consider the two parabolic pencils $\langle A, Q\rangle$ and $\langle A, R\rangle$. In the first of these there is one member, say L', which passes through P; and in the second there is likewise one member, say L'', which passes through P. The two stircles L', L'' must be distinct. If they were not, the stircle $L'=L''$ would be orthogonal to A, and pass through Q and R. But there is just one stircle orthogonal to a given stircle and passing through two points on it. Thus $L'=L''$ implies $L'=L''=L$, and thus P lies on L, which has been assumed not to be the case. The stircles ("lines") L' and L'' are members of the elliptic pencil passing through P and P_A, the inverse of P relative to A; furthermore, L' and L'' are tangent to L. These two stircles divide the elliptic pencil into two sets of stircles, such that all the stircles of one set cut L, while all the stircles of the other set do not cut L. Since this second set contains infinitely many members, (25c) is justified.

We now prove that in hyperbolic geometry the angle sum in any triangle is less than π. To do this, we deal first with a right-angled triangle (see Figure 3):

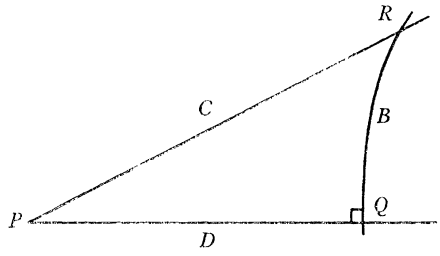

FIG. 3

THEOREM. *If PQR is a right triangle in the hyperbolic plane, with Q the right angle, then*

$$\cos R = \sin P \cosh 2r, \tag{26}$$

where r is the length of the side opposite R.

Proof. In the Poincaré model, let $A=(1, 0, 0, \frac{1}{2})$, and let P be at the center of the circle A. Let PQ coincide with the positive x_1-axis and let PR lie in the first quadrant. Then

$$P = (1, 0, 0, 0), \qquad Q = (1, a, 0, -a^2/2),$$

where a is some positive number less than 1. Using the distance formula (23) we find that $r=d(P, Q)$ is given by $\sinh r = a(1-a^2)^{-1/2}$, or $\cosh 2r = (1+a^2)/(1-a^2)$. Let us denote the 4-vectors corresponding to the sides opposite P, Q, R by B, C, D. Then, using P for the angle between C and D we have

$$C = (0, \sin P, -\cos P, 0), \qquad D = (0, 0, 1, 0).$$

In order to determine the 4-vector B, we have the conditions $B\#A=0$, $B\#D=0$, $B\#Q=0$. These, together with the arbitrary choice of $b_0=1$ for the first component of B, lead to $B=(1, (a^2+1)/2a, 0, -\frac{1}{2})$, from which

$$\cos R = \frac{B\#C}{\sqrt{(B\#B)(C\#C)}} = \sin P \frac{1+a^2}{1-a^2} = \sin P \cosh 2r.$$

Since $\cosh 2r$ is greater than 1, (26) implies that $\cos R > \sin P = \cos(\frac{1}{2}\pi - P)$. Hence, $P+R<\frac{1}{2}\pi$. Thus the angle sum of a right triangle is less than π. Given a general triangle, we divide it into two right triangles by a perpendicular from a vertex to an opposite side, and readily conclude that its angle sum is less than π.

Formula (26) is one of a system of results in hyperbolic trigonometry, analogous to the formulas of spherical trigonometry, all of which can be derived on the same basis as (26).

In references 1 and 2 will be found details on the interpretation of the geometry of this article in 3-dimensional projective space. Reference 3 includes a summary of more advanced results in inversive and conformal geometry. Reference 4 is the standard treatment of bundles of circles and their properties.

A PARALLELOGRAM LAW FOR CERTAIN L_p SPACES

D. C. KAY, University of Oklahoma

A slight variation of the parallelogram law was recently found to play a role in extending Haantjes' proof of a theorem on curvature [3] to normed vector spaces. This condition replaces the ptolemaic inequality used in that proof, but applies to a wider class of linear spaces than those which are ptolemaic. In [4], Schoenberg has shown that the only linear spaces which are ptolemaic are Euclidean. The property we wish to study here however holds for certain spaces which are not Euclidean:

DEFINITION. *A vector space V with norm $\| \ \|$ is said to obey a weak parallelogram law provided there exists a positive constant $\gamma<1$ such that for all x and y belonging to V,*

$$\|x+y\|^2 + \gamma^2\|x-y\|^2 \leqq 2\|x\|^2 + 2\|y\|^2. \tag{1}$$

The constant γ is restricted in this manner because the inequality cannot hold without qualification if $\gamma > 1$ as is clear by setting $y = -x$. Also, the inequality for $\gamma = 1$ implies (as is shown by Schoenberg's result) that V is an inner product space with the usual parallelogram law $\|x+y\|^2+\|x-y\|^2 = 2\|x\|^2+2\|y\|^2$, and finally, (1) imposes no condition at all if $\gamma \leqq 0$.

Since the parallelogram law implies the weak parallelogram law in a normed vector space (with $\gamma = 1/2$, say), but presumably not conversely, our terminology is apparently justified. The immediate question to answer is whether there exist vector spaces which satisfy the weak but not the full parallelogram law. It is the purpose of this paper to answer this question affirmatively for certain finite-dimensional spaces and in particular to prove that all finite-dimensional L_p spaces $(1 < p \leqq 2)$ obey a weak parallelogram law. We do not deal with the curvature theorem of Haantjes since that appears elsewhere (see [6]).

1. A sufficient condition for the weak parallelogram law. The following argument will yield a property of the unit sphere which guarantees the weak parallelogram law. Let x and y be two linearly independent points in a normed vector space V, the truth of (1) being self-evident otherwise. With $z = x+y$, define

$$x' = \frac{x}{\|x\|}, \qquad y' = \frac{y}{\|y\|}, \qquad z' = \frac{z}{\|z\|}.$$

By the linear independence of x and y, x', y', and z' are three distinct points lying on the unit sphere U. Let o be the zero vector of V. If U is strictly convex, o, x', z', and y' are the vertices of a convex quadrilateral which lies in the two-flat F determined by o, x', and y', and therefore, there is a unique ellipse E in F with center o passing through x', y', and z'. Let $\| \ \|_E$ denote the norm in F with unit sphere E. That is, for $p \neq o$ in F and with p' either point of intersection of E and the line determined by o and p, define

$$\|p\|_E = \frac{e(o, p)}{e(o, p')},$$

with $e(u, v)$ a Euclidean metric for F. From now on, $e(u, v)$ will be abbreviated by the simpler notation, uv. The norm $\| \ \|_E$ is "Euclidean" since the affine transformation ϕ mapping E onto the unit circle with center o yields

$$\|p\|_E = \frac{op}{op'} = \frac{o\phi(p)}{o\phi(p')} = o\phi(p).$$

Thus, the ordinary parallelogram law holds for this norm. Setting $w = x-y$ we have

$$\|z\|_E^2 + \|w\|_E^2 = 2\|x\|_E^2 + 2\|y\|_E^2.$$

Moreover, $\|z\|_E = \|z\| = \|x+y\|$, $\|x\|_E = \|x\|$, and $\|y\|_E = \|y\|$. If we set $w'' = w/\|w\|_E$,

then $\|w\|_E = \|w\|/\|w''\| = \|x-y\|/\|w''\|$. Making substitutions we obtain

$$\|x+y\|^2 + \|w''\|^{-2}\|x-y\|^2 = 2\|x\|^2 + 2\|y\|^2.$$

This gives us (1) provided $\|w''\|$ is bounded. Since w'' is a point on E, we need only ask for the boundedness of the diameters of all ellipses such as E. But E was merely an ellipse with center o and having six points of contact, $\pm x'$, $\pm y'$, and $\pm z'$, with U. Thus we may state:

LEMMA 1. *The weak parallelogram law is valid in a normed linear space with strictly convex unit sphere U and zero vector o provided the diameters of all ellipses with center o having six distinct points of contact with U are bounded, as measured by the norm.*

This lemma is of primary interest in the case of two-dimensional spaces where the condition given can be studied in terms of the curvature of the unit sphere U. Intuitively, a unit sphere having positive curvature at every point cannot have a sequence of ellipses, such as those defined above, whose diameters are unbounded. Thus, the norm defined by U will obey a weak parallelogram law. We shall prove a more general theorem which will apply to a two-dimensional L_p space, $p \geqq 1$, where we cannot assume that the curvature of U exists at every point. We shall subsequently find the following lemmas useful. Since the first is an easy exercise in elementary calculus, while the second is a standard result in the theory of convex bodies, we omit the proofs.

LEMMA 2. *If $h(x)$ is a real-valued function of the real variable x on the interval $a \leqq x \leqq b$ where $a < b$, and the derivative $h'(x)$ exists except possibly at $x = c$ for $a < c < b$ but $h(x)$ is strictly increasing (decreasing) in a neighborhood of c, then Rolle's Theorem holds for $h(x)$ on that interval. That is, if $a \leqq a_1 < b_1 \leqq b$ and $h(a_1) = h(b_1)$ then there exists a c_1 such that $h'(x)$ exists at c_1, $h'(c_1) = 0$, and $a_1 < c_1 < b_1$.*

LEMMA 3. *Let θ represent the Euclidean angle $\angle(o, p, q)$ where p and q are points of a bounded two-dimensional convex curve U with o any fixed interior point of U, with uv denoting a Euclidean metric, as before. Then if $a = \inf_{x \in U} ox$ and $pq < 2a$, θ is bounded away from 0 and π.* (For later reference we put $b = \sup_{x \in U} ox$.)

We shall also need the following rather trivial result:

LEMMA 4. *With the notation of Lemma 3, suppose that U is symmetric about o and that E_n is a sequence of ellipses centered at o meeting U in six distinct points whose Euclidean diameters d_n tend to infinity. Then the width w_n of E_n (defined by $w_n = 2 \inf_{x \in E_n} ox$) is bounded away from zero.*

Proof. Suppose w_n is not bounded away from zero. We may assume without loss of generality that $\lim_n w_n = 0$. We make the observation that there is therefore some subsequence $\{k\}$ of $\{n\}$ such that the six points in common between E_k and U converge to either u or $-u$ for some point u on U. Since E_k meets U

in six points, we can find two of those points in the same quadrant formed by the axes of E_k. Let us choose the notation so that p_k and q_k are those two points and $op_k > oq_k$. Thus, p_k and q_k converge to the same point on U and consequently, $p_kq_k < 2a$ for all k sufficiently large. From the elementary properties of ellipses, if ϕ_k is the angle between the tangent of E_k at p_k and the line through o and p_k, while $\theta_k = \angle(o, p_k, q_k)$, then $|\tan \theta_k| < |\tan \phi_k|$ for each k. But setting $r_k = op_k$ we can easily compute $|\tan \phi_k|$ in terms of r_k, d_k, and w_k:

$$|\tan \phi_k| = \frac{w_k}{\sqrt{(1 - 4r_k^2/d_k^2)(4r_k^2 - w_k^2)}}.$$

It then follows that $\lim_k \tan \theta_k = 0$, which contradicts Lemma 3.

2. Two-dimensional Minkowski spaces. In the following theorem we shall assume that U, as a plane convex curve, is differentiable at every point and twice differentiable at all but finitely many points. That is, if U is represented locally by $y = f(x)$ in some rectangular coordinate system (x, y), then $f(x)$ has first derivative $f'(x)$ for all x in the interval of definition of $f(x)$, while the second derivative $f''(x)$ exists at all but a finite number of points in that interval.

THEOREM 1. *If U is the unit sphere of a two-dimensional Minkowski geometry having the differentiability properties mentioned above, the weak parallelogram law holds if and only if the curvature of U wherever it exists is bounded away from zero.*

Proof. Sufficiency. Suppose the curvature of U is bounded away from zero. In view of Lemma 1, it suffices to show that no sequence of ellipses E_n having six points of contact with U and centered at o, the center of U, and whose diameters d_n tend to infinity, exists. To that end, suppose that such a sequence does exist, and let the six points of contact for E_n and U be $\pm p_{ni}$ $(i = 1, 2, 3)$. Since these sequences of points have convergent subsequences, we may assume without loss of generality that $\lim_n p_{ni} = p_i$ for each i. The hypothesis implies that U is strictly convex, so it is clear that three of the points $\pm p_i$ $(i = 1, 2, 3)$ coincide with p_1 while the others coincide with $-p_1$. Let the notation be such that $\lim_n p_{ni} = p_1$ for each i. Choose a rectangular coordinate system (x, y) with origin o and the positive y-axis passing through p_1. Then E_n has an equation of the form

$$a_nx^2 + 2b_nxy + c_ny^2 = 1, \tag{2}$$

where $a_n > 0$, $c_n > 0$ and $b_n^2 - a_nc_n < 0$. Now the diameter of E_n is given by

$$d_n = 2\sqrt{2}[a_n + c_n - \sqrt{(a_n + c_n)^2 + 4(b_n^2 - a_nc_n)}]^{-1/2} \tag{3}$$

while the width (as defined in Lemma 4) is

$$w_n = 2\sqrt{2}[a_n + c_n + \sqrt{(a_n + c_n)^2 + 4(b_n^2 - a_nc_n)}]^{-1/2}. \tag{4}$$

By Lemma 4, w_n is bounded away from zero so that the quantity inside the bracket in (4) is bounded. Thus, a_n and c_n, being positive, must both be bounded,

and therefore so is b_n. It then follows that $\{a_n\}$, $\{b_n\}$, and $\{c_n\}$ have convergent subsequences, say $\{a_k\}$, $\{b_k\}$, and $\{c_k\}$, and hence, $\lim_k a_k = a$, $\lim_k b_k = b$, and $\lim_k c_k = c$. Since $d_n^{-1} \to 0$, (3) implies that $\lim_k b_k^2 - a_k c_k = 0$ and therefore $b^2 = ac$. If the coordinates of p_{ki} are (x_{ki}, y_{ki}) for each k and for $i = 1, 2, 3$, which must satisfy equation (2) for $n = k$, then, since $x_{ki} \to 0$, we have $c > 0$ and obtain $(0, 1/\sqrt{c})$ as the coordinates of p_1. In some neighborhood of p_1 U has the representation $y = f(x)$, and by hypothesis, we may assume the neighborhood is such that $f'(x)$ exists for all x and $f''(x)$ exists for all x except, possibly, $x = 0$. For all sufficiently large k and each i, x_{ki} will fall in the interval of definition of $f(x)$. For each such k define the function

$$g_k(x) = a_k x^2 + 2b_k xy + c_k y^2 - 1, \quad \text{where} \quad y = f(x).$$

Since $g_k(x_{ki}) = g_k(x_{k2}) = g_k(x_{k3}) = 0$ (we shall assume $x_{k1} < x_{k2} < x_{k3}$), we may apply Rolle's Theorem and find numbers x_{k4} and x_{k5} such that $g_k'(x_{k4}) = g_k'(x_{k5}) = 0$, with $x_{k1} < x_{k4} < x_{k2} < x_{k5} < x_{k3}$. Then

$$(5) \quad (1/2)g_k'(x) = a_k x + b_k y + y'(b_k x + c_k y) = 0, \qquad \text{for } x = x_{k4},\ x = x_{k5}.$$

As $k \to \infty$ we have $x = x_{k4} \to 0$, and therefore $y = f(x_{k4}) \to 1/\sqrt{c}$, so we find that since $y' < 0$, $y' = f'(x_{k4}) \to -\sqrt{a/c}$. The convexity of U implies that $f'(x)$ is continuous where it exists, so we have $f'(0) = -\sqrt{a/c}$. Next, compute $g_k''(x)$, $x \neq 0$:

$$(6) \qquad (1/2)g_k''(x) = a_k + 2b_k y' + c_k y'^2 + y''(b_k x + c_k y).$$

For all x sufficiently close to 0 the quantity $b_k x + c_k y$ is positive for all k. Hence, for all such x, $y''(b_k x + c_k y) < -\epsilon(b_k x + c_k y)$, where $\epsilon > 0$ is the number guaranteed by hypothesis (and our choice of coordinate system) such that $y'' < -\epsilon$ for all x. That is,

$$(7) \qquad (1/2)g_k''(x) < a_k + 2b_k y' + c_k y'^2 - \epsilon(b_k x + c_k y).$$

Now, the limit of the right-hand member of (7) as x tends to zero is

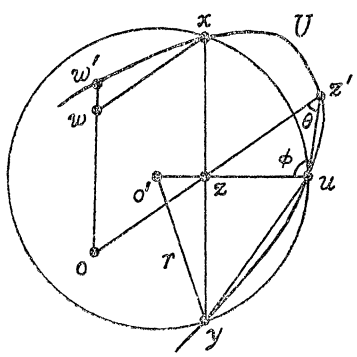
$$a_k - 2b_k\sqrt{a/c} + c_k(a/c) - \epsilon c_k/\sqrt{c}$$

and the limit of this as k tends to infinity is $-\epsilon\sqrt{c}$. Therefore, for all sufficiently large k there exists a neighborhood N_k about $x = 0$ for which

$$g_k''(x) < -\epsilon\sqrt{c}/4 < 0$$

holds for all x. That is, $g_k'(x)$ is decreasing for x in N_k. By Lemma 3 Rolle's Theorem applies to $g_k'(x)$ and we can find an x_{k6} such that $g_k''(x_{k6}) = 0$ and $x_{k4} < x_{k6} < x_{k5}$. Then (6) becomes

$$a_k + 2b_k y' + c_k y'^2 + y''(b_k x + c_k y) = 0, \qquad x = x_{k6}.$$



As $k \to \infty$, $x_{k6} \to 0$ and the above equation implies $f''(x_{k6}) \to 0$, a contradiction. It follows that no sequence E_n exists, and therefore, the weak parallelogram law is valid.

Necessity. Suppose that the weak parallelogram law holds, and that the curvature K of U exists at some point p. By hypothesis, the curve U is twice differentiable in some neighborhood of p. Let $\{x_k\}$ and $\{y_k\}$ be two sequences of points on U converging to p, $x_k \neq y_k$ for each k. Dropping the subscripts for the moment, define $z=(x+y)/2$, $z'=z/\|z\|$, $w=(x-y)/2$, $w'=w/\|w\|$, and let u be that point on U closest to x such that $xu=uy$. Further, let o' be the center of the circle passing through x, u, and y, and r its radius, and set $\theta=\angle(u, z', z)$, $\phi=\angle(z, u, z')$. Now since $\|x\|=1$ and $\|y\|=1$, we have

$$\frac{2\|x\|^2+2\|y\|^2-\|x+y\|^2}{\|x-y\|^2}=\frac{1-\|z\|^2}{\|w\|^2}=\frac{1-(oz/oz')^2}{(ow/ow')^2}.$$

Simplifying and using the law of sines for triangle (u, z, z') the latter becomes

$$\frac{zu}{zy^2}\cdot\frac{\sin\phi}{\sin\theta}\cdot\frac{ow'^2}{oz'^2}(oz'+oz)=\frac{1}{2r-zu}\cdot\frac{\sin\phi}{\sin\theta}\cdot\frac{ow'^2}{oz'^2}(oz'+oz).$$

By the weak parallelogram law the above remains no smaller than the constant $\gamma>0$. Lemma 3 shows that $\sin\theta\geqq\delta>0$ for some constant δ, and if a and b are the numbers defined, we have $ow'\leqq b$, $oz'+oz\leqq 2b$, and $oz'\geqq a$. Thus,

$$0<\gamma\leqq\frac{1}{r_k-(z_ku_k)/2}\cdot\frac{b^3}{\delta a^2},$$

replacing the subscripts. Since the osculating circle exists at p we have $\lim_k 1/r_k=K$. Both, z_k and u_k converge to p so we have $\lim_k (r_k-(z_ku_k)/2)^{-1}=K$. Hence there exists k for which $(r_k-(z_ku_k)/2)^{-1}<2K$. We have therefore proved that wherever K exists it must satisfy the inequality

$$0<\gamma<\frac{2Kb^3}{\delta a^2}.$$

Thus K is bounded away from zero, and this completes the proof of the theorem.

Theorem 1 gives us full information regarding two-dimensional L_p spaces, for then U is the set of points (x, y) satisfying $|x|^p+|y|^p=1$, $p\geqq 1$. One can readily observe the curvature behavior of U in the first quadrant, $0\leqq x<1$. For $0<x<1$ and $0<y<1$ we have $y=(1-x^p)^{1/p}$, so the usual formula for curvature K applies. Thus,

$$K=\frac{(p-1)(xy)^{p-2}}{(x^{2p-2}+y^{2p-2})^{3/2}}. \tag{8}$$

Now, if $p=1$ we find $K=0$ for all x, $0<x<1$. If $1<p<2$ the curvature is positive for all x, becoming infinite as x tends to zero or unity, so K is bounded away from zero, where it exists, in $0\leqq x\leqq 1$. For $p=2$, $K=1$ for all x (of course, the full parallelogram law holds in this case), and for $p>2$, K tends to zero as x approaches zero. By the symmetry of U with respect to the coordinate axes, the curvature behavior for the first quadrant carries over to the other three. Hence, we have proved:

THEOREM 2. *For two-dimensional L_p spaces $(p\geqq 1)$, the weak parallelogram law holds iff $1<p\leqq 2$.*

3. Finite-dimensional L_p spaces. For $n\geqq 1$, an n-dimensional L_p space is the set of all n-tuples $x=(x_1, x_2, \cdots, x_n)$, x_k real, with the norm defined by $\|x\|=(\sum_{k=1}^n |x_k|^p)^{1/p}$. The next theorem establishes the fact that the restriction to dimension two in Theorem 2 is inessential.

THEOREM 3. *In an L_p space of dimension $n>1$ $(p\geqq 1)$, the weak parallelogram law holds iff $1<p\leqq 2$.*

Proof. The necessity of the condition is obviously a direct consequence of Theorem 2. Hence, suppose V is an L_p space with $1<p\leqq 2$, and let $x=(x_1, x_2, \cdots, x_n)$ and $y=(y_1, y_2, \cdots, y_n)$ be any two points of V. We must then prove for some positive $\gamma_n<1$ independent of x and y, that

$$\Big(\sum |x_k+y_k|^p\Big)^{2/p}+\gamma_n^2\Big(\sum |x_k-y_k|^p\Big)^{2/p} \leqq 2\Big(\sum |x_k|^p\Big)^{2/p}+2\Big(\sum |y_k|^p\Big)^{2/p}, \tag{9}$$

where for convenience $\sum$ denotes summation on k from 1 to n. Since (9) is trivial for $x=y$ we may assume that for at least one k, $x_k\neq y_k$. Therefore, but for a reordering of the subscripts, $|x_n-y_n|$ is maximal among $|x_k-y_k|$, $k=1, 2, \cdots, n$, and is positive. The validity of the weak parallelogram law for two dimensions enables us to produce a positive $\gamma<1$ such that for any four given real numbers z_1, z_2, w_1, w_2,

$$(|z_1+w_1|^p+|z_2+w_2|^p)^{2/p}+\gamma^2(|z_1-w_1|^p+|z_2-w_2|^p)^{2/p} \leqq 2(|z_1|^p+|z_2|^p)^{2/p}+2(|w_1|^p+|w_2|^p)^{2/p}. \tag{10}$$

The triangle inequality for dimension $n-1$ applied to the points $(x_1, x_2, \cdots, x_{n-1})$ and $(y_1, y_2, \cdots, y_{n-1})$ yields

$$(11) \qquad (\sum' \mid x_k + y_k \mid^p)^{1/p} \leqq (\sum' \mid x_k \mid^p)^{1/p} + (\sum' \mid y_k \mid^p)^{1/p}$$

where $\sum'$ indicates summation on k from 1 to $n-1$. Therefore,

$$\begin{aligned} 2(\sum \mid x_k \mid^p)^{2/p} + 2(\sum \mid y_k \mid^p)^{2/p} - (\sum \mid x_k + y_k \mid^p)^{2/p} \\ (12) \qquad \geqq 2(\sum \mid x_k \mid^p)^{2/p} + 2(\sum \mid y_k \mid^p)^{2/p} \\ - (\mid (\sum' \mid x_k \mid^p)^{1/p} + (\sum' \mid y_k \mid^p)^{1/p} \mid^p + \mid x_n + y_n \mid^p)^{2/p}. \end{aligned}$$

Now set $z_1 = (\sum' \mid x_k \mid^p)^{1/p}$, $z_2 = x_n$, $w_1 = (\sum' \mid y_k \mid^p)^{1/p}$, $w_2 = y_n$, and apply (10). The right-hand member of (12) is not less than

$$\gamma^2(\mid (\sum' \mid x_k \mid^p)^{1/p} - (\sum' \mid y_k \mid^p)^{1/p} \mid^p + \mid x_n - y_n \mid^p)^{2/p} \geqq \gamma^2(\mid x_n - y_n \mid^p)^{2/p}.$$

But from our choice of $\mid x_n - y_n \mid$ we have $n \mid x_n - y_n \mid^p \geqq \sum \mid x_k - y_k \mid^p$. Thus,

$$\begin{aligned} 2(\sum \mid x_k \mid^p)^{2/p} + 2(\sum \mid y_k \mid^p)^{2/p} - (\sum \mid x_k + y_k \mid^p)^{2/p} \\ \geqq \frac{\gamma^2}{n^{2/p}} (\sum \mid x_k - y_k \mid^p)^{2/p} > \frac{\gamma^2}{n^2} (\sum \mid x_k - y_k \mid^p)^{2/p} \end{aligned}$$

and hence, (9) holds with $\gamma_n = \gamma/n > 0$, which completes the proof.

The fact that $\gamma_n \to 0$ as $n \to \infty$ means that we cannot extend our proof to the infinite-dimensional case. It is not known whether an infinite-dimensional space, besides Hilbert space, possesses a weak parallelogram law. Such a space, if it exists, must of necessity be uniformly convex, an immediate consequence of (1) restricted to points on the unit sphere. (See [1] for a discussion of uniformly convex spaces and certain inequalities resembling the parallelogram law, valid for L_p spaces of arbitrary dimension.) The question remains whether, in particular, an infinite-dimensional L_p space possesses a weak parallelogram law.

FINITE ADDITIVITY, INVERTIBILITY, AND SIMPLE EXTENSIONS OF TOPOLOGIES

DAVID RYEBURN, Kenyon College

1. Introduction. Doyle and Hocking [2] defined a topological space X to be *invertible* if, for every nonempty open subset O of X, there is a homeomorphism $f:X\to X$ such that $f(X-O)\subset O$. Then f is said to be an *inverting homeomorphism* for O. Doyle and Hocking [2] proved that if an invertible space X possesses a nonempty open subspace which is a T_i-space ($i=0$, 1, or 2) or whose closure is compact, then X has the property in question. Levine [6] proved that if an invertible space X possesses a nonempty open subspace which is separable, satisfies the first or second axiom of countability, is regular, or is normal, then X has the property in question. Gray [3] proved that if an invertible space X possesses a nonempty open subspace which is metrizable, then X is metrizable. In this paper it will be noted that certain topological properties are possessed by spaces having finite open or closed coverings the members of which possess the properties, and some of the results of Doyle and Hocking [2], Levine [6], and Gray [3] will follow from these facts as will similar results for certain other topological properties. In addition, invertibility can be defined analogously for uniform spaces, and again the whole space will possess certain properties holding for subspaces.

In another paper, Levine [5] defined one topology, $\mathfrak{T}^*$, to be a *simple extension* of another topology, $\mathfrak{T}$, on the same set X, in case $\mathfrak{T}^*=\{U\cup(V\cap A): U, V\in\mathfrak{T}\}$ for some $A\notin\mathfrak{T}$. He investigated the question of whether $(X, \mathfrak{T}^*)$ has certain properties possessed by $(X, \mathfrak{T})$; the properties included regularity, complete regularity, the Tychonoff property, and normality. Some of the results, and others like them, may be obtained by using methods similar to those used to investigate invertibility.

2. Summary of finite additivity results. A topological property P is said to be *finitely o-additive* in case whenever $X=A\cup B$ with A, B open subspaces of X possessing property P, X must also possess property P. Similar definitions may be given for *finitely c-additive*, where the sets A and B are closed, and for *finitely s-additive*, where the sets A and B are complementary clopen sets (constituting a separation of X).

It is immediate that the T_0 property, the T_1 property, metacompactness (every open covering has a point finite open refinement), pseudocompactness (every real-valued continuous function is bounded), local compactness, σ-compactness, the first countability property, the second countability property, separability, the Lindelöf property, local connectedness, and the countable chain property (every disjoint class of open sets is countable) are finitely o-additive. It is likewise immediate that regularity, the T_3 property, the property of being an $\aleph_0$-space (a regular space with a countable class $\mathcal{S}$ of subsets such that if C is a compact subset and U is an open subset with $C\subset U$, then $C\subset S\subset U$ for some $S\in\mathcal{S}$) [7], compactness, countable compactness, sequential compact-

ness, pseudocompactness, separability, the Lindelöf property, and the countable chain property are finitely c-additive. Mrówka [9] proved that normality is finitely c-additive, and thus the T_4 property, hereditary normality, and the T_5 property are finitely c-additive. Hence it is immediate that perfect normality and the T_6 property are finitely c-additive. Michael [8] proved that paracompactness is finitely c-additive, and thus hereditary paracompactness is also finitely c-additive. De Groot [1] and Nagata [10] proved that metrizability is finitely c-additive. It is immediate that complete regularity, the Tychonoff property, collectionwise normality (for every discrete family $\{F_i: i\in I\}$ of closed subsets there is a disjoint family $\{U_i: i\in I\}$ of open subsets with $F_i\subset U_i$ for each $i\in I$), and strong paracompactness (every open covering has a star-finite open refinement) are finitely s-additive.

3. Invertibility and topological properties.

THEOREM 1. *Let X be a topological space invertible in one of its nonempty open subsets, O, and suppose that O enjoys a finitely o-additive topological property P. Then X enjoys P.*

Proof. Let f be an inverting homeomorphism for O. Then $f(O)$ is open and $X=O\cup f(O)$. Since O and $f(O)$ enjoy P, and P is finitely o-additive, X enjoys P.

THEOREM 2. *Let X be a topological space invertible in one of its nonempty open subsets, O, and suppose that $Cl(O)$ enjoys a finitely c-additive topological property P. Then X enjoys P.*

Proof. Let f be an inverting homeomorphism for O. Then $f(\mathrm{Cl}(O))$ is closed and $X=\mathrm{Cl}(O)\cup f(\mathrm{Cl}(O))$. Since $\mathrm{Cl}(O)$ and $f(\mathrm{Cl}(O))$ enjoy P and P is finitely c-additive, X enjoys P.

THEOREM 3. *Let X be a topological space and O a nonempty open subset enjoying a c-hereditary, finitely c-additive property P. If X is invertible and if P implies normality then X enjoys property P.*

Proof. Let f be an inverting homeomorphism for O. Then $X=O\cup f(O)$, and both O and $f(O)$ are open in X. X is invertible and O is normal, hence X is normal [6]. Thus there are closed sets F_1 and F_2 with $F_1\subset O$, $F_2\subset f(O)$, and $X=F_1\cup F_2$. Since F_1 and F_2 enjoy P and P is finitely c-additive, X must enjoy P.

Theorems 1, 2, and 3 and the additivity results of Section 2 immediately yield the results referred to in Section 1.

4. Invertibility in uniform spaces. If X is a uniform space and Y is a nonempty subset of X, then X is said to be uniformly invertible in Y in case there is a uniform isomorphism $f: X\to X$ for which $f(X-Y)\subset Y$.

THEOREM 4. *Let $(X, \mathfrak{U})$ be a uniform space having a nonempty subset Y for which $(Y, \mathfrak{U}\cap(Y\times Y))$ has a countable uniformity base and in which there is an inverting uniform isomorphism f such that $(Y\times Y)\cup(f(Y)\times f(Y))\in\mathfrak{U}$. Then $(X, \mathfrak{U})$ has a countable uniformity base.*

Proof. Let $\mathfrak{B}$ be a countable uniformity base for $(Y, \mathfrak{U}\cap(Y\times Y))$. Then for each $B\in\mathfrak{B}$ we have $B=W\cap(Y\times Y)$ for suitable $W\in\mathfrak{U}$. Since f is a uniform isomorphism, $(f\times f)(W)\in\mathfrak{U}$. By hypothesis $(Y\times Y)\cup(f(Y)\times f(Y))\in\mathfrak{U}$. Thus

$$W^{\#} = [W \cap (f\times f)(W)] \cap [(Y\times Y)\cup(f(Y)\times f(Y))] \in \mathfrak{U}.$$

But $W^{\#}\subset[W\cap(Y\times Y)]\cup[(f\times f)(W)\cap(f(Y)\times f(Y))]=B\cup(f\times f)(B)$. Thus for each $B\in\mathfrak{B}$ we have $B\cup(f\times f)(B)\in\mathfrak{U}$. Now let $U\in\mathfrak{U}$. Then $(f^{-1}\times f^{-1})(U)\in\mathfrak{U}$ and thus for some $B\in\mathfrak{B}$ we have $B\subset U\cap(f^{-1}\times f^{-1})(U)\cap(Y\times Y)$. Hence $B\subset U$, $(f\times f)(B)\subset U$, and $B\cup(f\times f)(B)\subset U$. Thus $\{B\cup(f\times f)(B): B\in\mathfrak{B}\}$ is a countable uniformity base for X.

LEMMA. *Let $(X, \mathfrak{U})$ be a uniform space uniformly invertible in every nonempty open subset, and let O be a nonempty open subset such that $(O, \mathfrak{U}\cap(O\times O))$ is a Hausdorff space. Then $(X, \mathfrak{U})$ is a Hausdorff space.*

Proof. Let $x\neq y$, $x\in X$, $y\in X$. First suppose that $x\in O$ and $y\in O$. Then for some $V\in\mathfrak{U}\cap(O\times O)$ we have $(x, y)\notin V$. If $V=W\cap(O\times O)$, $W\in\mathfrak{U}$, then $(x, y)\notin W$. Now suppose that $y\notin O$. Then $O-\{x\}$ is a Hausdorff space and is open in X, and by inverting in $O-\{x\}$ we return to the case already considered.

Using Theorem 4 and the lemma we obtain

THEOREM 5. *Let $(X, \mathfrak{U})$ be a uniform space uniformly invertible in every nonempty open subset, and let O be a nonempty open subset for which $(O, \mathfrak{U}\cap(O\times O))$ is metrizable and in which there is an inverting uniform isomorphism f such that $(O\times O)\cup(f(O)\times(f(O))\in\mathfrak{U}$. Then $(X, \mathfrak{U})$ is metrizable.*

The following example shows that the condition $(O\times O)\cup(f(O)\times f(O))\in\mathfrak{U}$ cannot be omitted. Let I be an uncountable set, S a metric space, $X=S\times I\times\{1\}$, $Y=S\times I\times\{2\}$, $Z=X\cup Y$. For each cofinite subset J of I and each natural number n let

$$A(n) = \bigcup_{i\in I}\{((s, i, 1), (t, i, 1)): s, t\in S \text{ and } d(s, t) < 1/n\},$$

$$B(n) = \bigcup_{i\in I}\{((s, i, 2), (t, i, 2)): s, t\in S \text{ and } d(s, t) < 1/n\},$$

$$C(J, n) = \bigcup_{j\in J}\{((s, j, 1), (t, j, 2)): s, t\in S \text{ and } d(s, t) < 1/n\},$$

$$D(J, n) = \bigcup_{j\in J}\{((s, j, 2), (t, j, 1)): s, t\in S \text{ and } d(s, t) < 1/n\},$$

and let $E(J, n)=A(n)\cup B(n)\cup C(J, n)\cup D(J, n)$. Then the class $\mathfrak{E}$ of all sets of the form $E(J, n)$ is a base for some uniformity $\mathfrak{U}$. Now suppose that $\mathfrak{B}=\{B_k: k=1, 2, \cdots\}$ is a countable base for $\mathfrak{U}$. For each k there is a cofinite set $J(k)$ and there is a natural number $n(k)$ such that $E(J(k), n(k))\subset B_k$. Thus the sets $E(J(k), n(k))$ form a countable base also. Note that $\bigcap_{k=1}^{\infty} J(k)$ is cocountable, while I is uncountable. If L is a cofinite subset of I with $L\supset\bigcap_{k=1}^{\infty} J(k)$ then for some k we should have $E(J(k), n(k))\subset E(L, 1)$, but this contradicts the

choice of L. Thus no such countable base exists. Yet $\{A(n): n=1, 2, \cdots\}$ and $\{B(n): n=1, 2, \cdots\}$ are countable bases for the subspaces X and Y respectively. There is a natural inversion interchanging X and Y, and thus by Theorem 5 the set $(X\times X)\cup(Y\times Y)$ must not be a member of $\mathfrak{U}$. Note that this example shows that the condition $(O\times O)\cup(f(O)\times f(O))\in\mathfrak{U}$ cannot be replaced by the condition that O be a clopen set. Note further that although the uniform space $(Z, \mathfrak{U})$ is not metrizable, the associated topological space is metrizable, since metrizability for topological spaces is finitely c-additive. The difficulty lies in the fact that X and Y come near each other for the uniformity, although they are complementary clopen sets.

THEOREM 6. *Let $(X, \mathfrak{U})$ be a uniform space uniformly invertible in a nonempty subset Y such that $(Y, \mathfrak{U}\cap(Y\times Y))$ is totally bounded. Then $(X, \mathfrak{U})$ is totally bounded.*

Proof. Let f be an inverting uniform isomorphism for Y. If $U\in\mathfrak{U}$ then $(f^{-1}\times f^{-1})(U)\in\mathfrak{U}$ and thus $U\cap(f^{-1}\times f^{-1})(U)\cap(Y\times Y)\in\mathfrak{U}\cap(Y\times Y)$. Hence, since $(Y, \mathfrak{U}\cap(Y\times Y))$ is totally bounded, there is a finite subset F of Y with

$$[U\cap(f^{-1}\times f^{-1})(U)\cap(Y\times Y)](F) = Y.$$

Thus $Y\subset U(F)$, $f(Y)\subset U(f(F))$, and $U(F\cup f(F))=X$. Hence $(X, \mathfrak{U})$ is totally bounded.

THEOREM 7. *Let $(X, \mathfrak{U})$ be a uniform space uniformly invertible in a nonempty subset Y such that $(Y, \mathfrak{U}\cap(Y\times Y))$ is complete. Then $(X, \mathfrak{U})$ is complete.*

Proof. Let $S: D\to X$ be a Cauchy net in X. Then either (i) S is frequently in Y, or (ii) S is eventually in $X-Y$. In case (i), let $D^*=S^{-1}(Y)$ and let $i: D^*\to D$ be the inclusion mapping. Then $S\circ i$ is a subnet of S and hence a Cauchy net in X. $S\circ i$ is still a Cauchy net when regarded as a net in Y, and hence converges (to a point $y\in Y$) by completeness of Y. Thus S has y as a cluster point, and since S is a Cauchy net S must converge to y. In case (ii), let $D^\#=S^{-1}(X-Y)$ and let $j: D^\#\to D$ be the inclusion mapping. If f is an inverting uniform isomorphism for Y, then $f\circ S\circ j$ converges to a point $y'\in Y$, and S converges to $f^{-1}(y')$.

5. Additivity and simple extensions. Throughout the remainder of this paper $(X, \mathfrak{T})$ will be a topological space, A will be a subset of X not a member of $\mathfrak{T}$, and $\mathfrak{T}^*=\{U\cup(V\cap A): U, V\in\mathfrak{T}\}$ will be a simple extension of $\mathfrak{T}$. Levine [5] observed that $(A, \mathfrak{T}^*\cap A)=(A, \mathfrak{T}\cap A)$ and $(X-A, \mathfrak{T}^*\cap(X-A))=(X-A, \mathfrak{T}\cap(X-A))$.

THEOREM 8. *If P is a finitely s-additive, c-hereditary topological property, $(X, \mathfrak{T})$ has P, and A is a $\mathfrak{T}$-closed subset of X, then $(X, \mathfrak{T}^*)$ has P iff $(X-A, \mathfrak{T}\cap(X-A))$ has P.*

Proof. Since $(X, \mathfrak{T})$ has P, A is $\mathfrak{T}$-closed, and P is c-hereditary, $(A, \mathfrak{T}\cap A)$ has P. But $(A, \mathfrak{T}^*\cap A)=(A, \mathfrak{T}\cap A)$, and A is $\mathfrak{T}^*$-clopen. If $(X-A, \mathfrak{T}^*\cap(X-A))=(X-A, \mathfrak{T}\cap(X-A))$ has P, then since $X-A$ is also $\mathfrak{T}^*$-clopen and P is

finitely s-additive, $(X, \mathfrak{T}^*)$ has P. Conversely, if $(X, \mathfrak{T}^*)$ has P then $X-A$ is $\mathfrak{T}^*$-closed and thus $(X-A, \mathfrak{T}^* \cap (X-A)) = (X-A, \mathfrak{T} \cap (X-A))$ has the c-hereditary property P.

Theorem 8 may be applied if $(X, \mathfrak{T})$ is normal, a T_4-space, paracompact, strongly paracompact, collectionwise normal, metacompact, compact, countably compact, sequentially compact, locally compact, σ-compact, or a Lindelöf space.

THEOREM 9. *If P is a finitely s-additive, hereditary topological property, $(X, \mathfrak{T})$ has P, and A is a $\mathfrak{T}$-closed subset of X, then $(X, \mathfrak{T}^*)$ has P.*

Proof. Since P is hereditary, $(X-A, \mathfrak{T} \cap (X-A))$ has P. By Theorem 8, $(X, \mathfrak{T}^*)$ has P.

Theorem 9 may be applied if $(X, \mathfrak{T})$ is regular, a T_3-space, completely regular, a Tychonoff space, hereditarily normal, a T_5-space, perfectly normal, a T_6-space, hereditarily paracompact, an $\aleph_0$-space, metrizable, first countable, or second countable.

GROUPS, GRAPHS, AND FERMAT'S LAST THEOREM

STEVEN BRYANT, San Diego State College

If we assign a point $P(x)$ in space to every element x of a group and join $P(x)$ with $P(x^2)$ by a directed line, we obtain a graph here called the graph of the group. We will show that any Abelian group with fewer than $(1093)^2$ elements is determined up to isomorphism by its graph, i.e., two such groups with isomorphic graphs are isomorphic. A stronger statement can be made: If the square of every element is known then the group is known up to isomorphism. This says that if the diagonal of the group table is given, then the isomorphism type of the group can be computed.

The prime 1093 is the first prime which satisfies $2^{p-1} \equiv 1 \pmod{p^2}$. Such primes are related to Fermat's Theorem, i.e., if no one of x, y, z are divisible by p and $2^{p-1} \not\equiv 1 \bmod p^2$ then $x^p + y^p \neq z^p$, [1].

For convenience, call p a *bad prime* if $2^{p-1} \equiv 1 \bmod p^2$. Now we can state the theorem.

THEOREM. *If G and H are Abelian groups of order n, and n is not divisible by the square of a bad prime, and there is a square preserving function on G onto H, then G and H are isomorphic. Furthermore, the isomorphism type of G can be computed if the square of every element of G is given.* (In the sense described above, i.e., if the main diagonal of the multiplication table of the group is known.)

Proof. The main part of the argument rests on the fact that under the hypotheses, the graph of the group G consists essentially of cycles and the number of elements in various size cycles determines the number of elements in the group G of each prime power order and this in turn determines G up to isomorphism.

CASE 1. n odd and n not only not divisible by the square of a bad prime but also not divisible by a bad prime, i.e., $n \not\equiv 0 \bmod p$ for any bad prime p. Then $n = p_1^{\alpha_1} \cdots p_m^{\alpha_m}$ with p_i odd and p_i not a bad prime for $i = 1, \cdots, m$.

So G is a direct product of groups $G_1, \cdots, G_m$, where $G_i = \{x: x \in G$ and the order of x is a power of $p_i\}$. Then, if x is an element of G, x is a unique product $x_1 \cdots x_m$ with x_i in G_i for $i = 1, \cdots, m$.

Now let k_i be the order of 2 mod p_i, i.e., $2^{k_i} \equiv 1 \bmod p_i$ and k_i is the smallest positive integer for which this holds. We need the following:

(1) *If p is not a bad prime and k is the order of* 2 mod p *then the order of* 2 mod p^α *is* $kp^{\alpha-1}$.

Proof. If $2^t \equiv 1 \bmod p^\alpha$ then $2^t \equiv 1 \bmod p^{\alpha-1}$. By induction $kp^{\alpha-2}$ divides t so $t = akp^{\alpha-2}$. If $a < p$ then $(a, p) = 1$ and $(2^k)^{ap^{\alpha-2}} \equiv 1 \bmod p^\alpha$. But $2^k = 1 + bp$ with $(b, p) = 1$ so $(1+bp)^{ap^{\alpha-2}} = 1 + cp^\alpha$. Expand the left side and cancel the ones, then divide by $p^{\alpha-1}$ this yields $ab \equiv 0 \bmod p$, a contradiction so $t \geqq kp^{\alpha-1}$. Finally $2^{kp^{\alpha-2}} \equiv 1 \bmod p^{\alpha-1}$ implies $2^{kp^{\alpha-1}} \equiv 1 \bmod p^\alpha$ by an easy argument, so $kp^{\alpha-1}$ is the order of 2 mod p^α.

(2) *Call the set $x, x^2, x^4, x^8, x^{16}, \cdots$ etc., the cycle to which x belongs and call the number of elements in this set the cycle order of x. If the (group) order of x is a power of a prime p then the (group) order of x is p^{α_0} if and only if the cycle order of x is kp^{α_0-1}.*

Proof. Let p^{α_0} be the order of x then $x^{p^{\alpha_0}} = 1$ with α_0 minimal. Let t be the cycle order of x. Then $x^{2^t} = x$ with t minimal so $2^t \equiv 1 \bmod p^{\alpha_0}$ and t is the order of 2 mod p^{α_0} so $t = kp^{\alpha_0-1}$. (This follows from (1).) Conversely, if the cycle order of x is $kp^{\alpha-1}$ and the order of x is p^{α_0}, let $t = kp^{\alpha-1}$; then $x^{2^t} = x$ with t minimal so $2^t \equiv 1 \bmod p^{\alpha_0}$ with t minimal hence $t = kp^{\alpha_0-1}$ so $\alpha = \alpha_0$.

Now let k_i be the order of 2 mod p_i. From (1) and (2) we have:

(3) *If x_i is an element of G_i then x_i has order p_i^α if and only if x_i has cycle order $k_i p_i^{\alpha-1}$.*

We also need to observe,

(4) *If the order of x is $p_i^{\beta_1} \cdots p_m^{\beta_m}$ then the cycle order of x is*

$$[k_1 p_1^{\beta_1 - 1}, \cdots, k_m p_m^{\beta_m - 1}]$$

i.e., the least common multiple of $k_1 p_1^{\beta_1 - 1}, \cdots, k_m p_m^{\beta_m - 1}$.

If the square of every element of G is given then the cycles of G are given and for each cycle order the number of elements which have that cycle order is given. What we have to see is that this determines the number of elements of G of prime power order for each prime divisor of n, the order of G. This will determine the primary subgroups of G up to isomorphism and hence determine G up to isomorphism.

Let $N_G(k_i p_i^\alpha)$ be the number of elements of G which have cycle order a divisor of $k_i p_i^\alpha$. The numbers $N_G(k_i p_i^\alpha)$ are known for $i = 1, \cdots, m$ and every α. We want to see that the isomorphism type is known, i.e., can be computed, if these numbers are known. The proof is by induction on m.

If $m = 1$ then $G = G_1$ and $N_G(k_1) - 1$ is the number of elements of order p_1 in G, $N_G(k_1 p_1) - N_G(k_1)$ is the number of elements of order p_1^2 in G_1 etc. So in this case G is known since $N_G(k_1 p_1^\alpha)$ is known for every α.

Now let the primes be labeled so that $p_1 > p_i$ for $i \neq 1$. Then $p_1 > p_i > k_i$ for $i \neq 1$ because k_i is the order of 2 mod p_i and hence $k_i \leqq p_i - 1$. Let p_1^γ be the maximal order of elements of G_1, so $y^\sigma = 1$ (where $\sigma = p_1^\gamma$) for every y in G_1 and γ is the smallest integer for which this holds. We continue by induction on γ, and for this we need:

(5) *If $x = x_1 \cdots x_m$ and the cycle order of x is $k_i p_i^\alpha$ with $i \neq 1$ then the cycle order of x_1 is either 1 or k_1.*

Proof. If the cycle order of x_1 is $k_1 p_1^\delta$ with $\delta \geqq 1$, then using (4), we see that p_1 divides k_i but $p_1 > k_i$.

(6) *If $\beta \geqq 1$ and $x = x_1 \cdots x_m$ and the cycle order of x is $k_1 p_1^\beta$ then the cycle order of x_1 is $k_1 p_1^\beta$ for if the cycle order of x_1 is $k_1 p_1^\delta$ with $\delta < \beta$ then using (4) we see that p_1 divides k_j for some $j \neq 1$ but this is impossible since $p_1 > k_j$ for every j. If $\delta > \beta$ then p_1 divides k_i which is also impossible since $k_1 \leqq p_1 - 1$.*

Let $N_G^*(p_1^\beta)$ be the number of elements in G_1 of order a divisor of p_1^β and let $\delta(i, \alpha) = N_G^*(p_1)$ or 1 depending on whether k_1 divides $k_i p_i^\alpha$. Then using (5) and (6) we have:

(7) *For $i \neq 1$ $N_G(k_i p_i^\alpha) = \delta(i, \alpha) N_{G/G_1}(k_i p_i^\alpha)$ for every $\alpha \geqq 0$.*

(8) *$N_G(k_1 p_1^{\alpha-1}) = N_{G_1}^*(p_1^\alpha) N_{G/G_1}(k_1 p_1^{\alpha-1})$ for every $\alpha \geqq 1$.*

Now if $\gamma = 1$, (8) consists of one equation: $N_G(k_1) = N_{G_1}^*(p_1) N_{G/G_1}(k_1)$ and since n the order of G is known, $N_{G_1}^*(p_1)$ is known. (In fact, $N_{G_1}^*(p_1) = p_1^{\alpha_1}$ where $n = p_1^{\alpha_1} \cdots p_m^{\alpha_m}$). Then for $i \neq 1$, $N_G(k_i p_i^\alpha)/\delta(i, \alpha)$ is known for every $\alpha \geqq 0$, hence

G/G_1 is known by inductive assumption. But G_1 is also known, i.e., G_1 is the product of α_1 cyclic groups of order p_1. Finally then G is known. (This means that we could write down equations containing $N^*_{G_j}(p_j^\alpha)$ as unknowns and solve these equations and that the solution is unique.)

To conclude the induction on γ, let $G^{p_1} = \{y: y \in G \text{ and } y = x^{p_1} \text{ for some } x \text{ in } G\}$. Then for $\alpha < \gamma$,

$$N_G(k_1 p_1^{\alpha-1}) = N_{G^{p_1}}(k_1 p_1^{\alpha-1}).$$

To see this observe that $G^{p_1} = G_1^{p_1} \times G_2 \times \cdots \times G_m$ and for $\alpha < \gamma$ any element in G_1 of order a divisor of p_1^α is in $G_1^{p_1}$ and hence any element in G_1 of cycle order a divisor of $k_1 p_1^{\alpha-1}$ is in $G_1^{p_1}$.

We also have for $i \neq 1$ and every $\alpha \geqq 0$,

$$N_G(k_i p_i^\alpha) = N_{G^{p_1}}(k_i p_i^\alpha).$$

To see this let x be an element of G of cycle order $k_i p_i^\alpha$, $i \neq 1$, then $x = x_1 \cdots x_m$ with x_1 in $G_1^{p_1}$ (this holds because of (5)), and x_j in G_j for $j \neq 1$. From this we have using (7) and (8).

(9) *For* $i \neq 1$, $N_G(k_i p_i^\alpha) = N_{G^{p_1}}(k_i p_i^\alpha) = \delta(i, \alpha) N_{G/G_1}(k_i p_i^\alpha)$ *and* $\alpha \geqq 0$.
(10) *For* $1 \leqq \alpha < \gamma$, $N_G(k_1 p_1^{\alpha-1}) = N_{G^{p_1}}(k_1 p_1^{\alpha-1}) = N^*_{G_1}(p_1^\alpha) N_{G/G_1}(k_1 p_1^{\alpha-1})$.
(11) $N_G(k_1 p_1^{\gamma-1}) = N^*_{G_1}(p_1^\gamma) N_{G/G_1}(k_1 p_1^{\gamma-1})$.

Using (9), (10), and (11) we have the following argument: The maximal order of elements in $G_1^{p_1}$ is $p_1^{\gamma-1}$ and $N_{G^{p_1}}(k_i p_i^\alpha)$ is known for $i \neq 1$ and $\alpha \geqq 0$. Also $N_{G^{p_1}}(k_1 p_1^{\alpha-1})$ is known for $\alpha < \gamma$. Hence $G_1^{p_1}$ is known by inductive assumption. But $G^{p_1} = G_1^{p_1} \times G_2 \times \cdots G_m$ so G/G_1 is known, therefore $N^*_G(p_1^\gamma)$ is known (because $N_G(k_1 p_1^{\gamma-1})$ is known). But then $N^*_{G_1}(p_1^\alpha)$ is known for every $\alpha \geqq 0$ so G_1 is known. Finally then G is known since G_1 and G/G_1 are known.

CASE 2. If n is odd and divisible by one or more bad primes but still not by the square of a bad prime, the analysis is essentially the same. For any bad prime p, in this case, the primary subgroup G_p is cyclic. The entire argument goes through because every element in G_p has order p (except for the identity) and the order of an element in G_p is p if and only if its cycle order is the order of 2 mod p.

CASE 3. If n is even let G_2 be the primary subgroup consisting of all elements whose order is a power of 2. The graph of G will contain trees as well as cycles but the trees in the graph determine the primary subgroup G_2 and in fact the isomorphism type of G_2 can be computed from these trees. The cycles which do not have trees sticking on them are the graph of G/G_2 and G/G_2 satisfies the hypothesis of Case 2, so then G/G_2 is known as well as G_2, hence G is known.

Remarks. The cyclic group of order $(1093)^2$ and the product of two cyclic groups of order 1093 have the same graph. To see this let p be any bad prime so $2^{p-1} \equiv 1 \bmod p^2$ and let k be the order of 2 mod p and let k' be the order of 2 mod p^2. Then $2^k \equiv 1 \bmod p$ and $2^{k'} \equiv 1 \bmod p^2$. From this we have $2^{kp} \equiv 1 \bmod p^2$

and $2^{k'} \equiv 1 \bmod p$, hence k' divides kp and k divides k' so $k' = k$ or $k' = kp$ but k' divides $p-1$ so $k' = kp$ is impossible and we have $k' = k'$.

In particular since 1093 is a bad prime, every element in the cyclic group of order $(1093)^2$ has the same cycle order. In the product of two cyclic groups of order 1093 every element has the same order, so these two groups have isomorphic graphs.

It is not known whether there are infinitely many bad primes or, for that matter, whether there are infinitely many primes which are not bad.

BING'S HOUSE WITH TWO ROOMS FROM A 1-1 CONTINUOUS MAP ONTO E^3

L. C. GLASER, Rice University

In [5], Proizvolov claimed to prove that if f is a 1-1 continuous map taking X onto E^n, where X is connected, locally compact and paracompact, and E^n is Euclidean n-space, then f is a homeomorphism. If all his results were correct one would have as an immediate corollary a difficult and well-known problem in point set topology. That is, if f is a monotone map of E^n onto E^n then is f a compact map? (A map γ taking X onto Y is monotone if counter images of points in Y are continua. A map f is compact if for each compact set $A \subset Y$, $f^{-1}(A)$ is compact.)

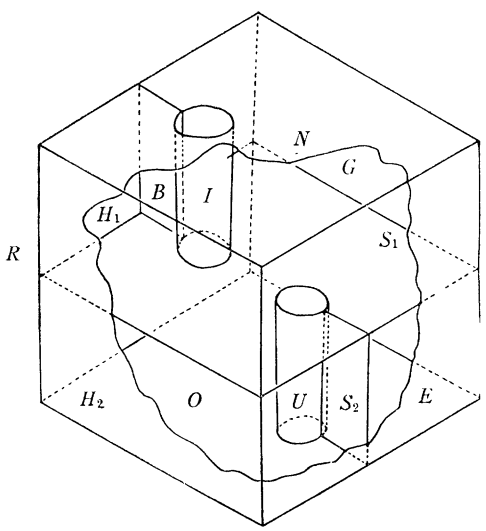
In [7], Kenneth Whyburn gave a particularly nice counterexample to Proizvolov's result by demonstrating a simple 1-1 continuous map taking a connected 3-manifold A with nonempty boundary onto E^3. The result obtained in [7] was first announced in [6]. An extensive generalization of [6, 7] was announced before either of the above in [2]. Earlier yet, in [1], numerous different examples were given showing a result similar to that of [7] (i.e., the domain spaces here were also 3-manifolds with boundary and the 1-1 continuous maps piecewise linear). In fact, the first counterexample to [5] was shown to the author by John Cobb in a class each of us had at the University of Wisconsin in 1963. His domain space was not a 3-manifold with boundary, in fact, it was not simply connected. Cobb's example also appears in [1].

It also was shown in [1] that the 3-ball, I^3, and the 3-sphere S^3, are the images of 1-1 continuous maps on noncompact 3-manifolds with nonempty boundary. These gave counterexamples to two other theorems of [5]. In [4] it is shown that under certain general conditions if f is any 1-1 continuous map taking M^n, an n-manifold with nonempty boundary onto E^n, then the 1-point compactification of $f(\text{Bd } M^n)$ is a contractible noncollapsible $(n-1)$-subcomplex of

S^n. In particular the 1-point compactification of $f(\text{Bd } M)$ in [4] is merely the Dunce Hat discussed in [8]. In [3], it is shown that E^n is in fact the 1-1 continuous image of E^n_+, the closed half space of E^n given by $\{(x_1, \cdots, x_n) \in E^n \mid x_n \geqq 0\}$.

The purpose of this note is to show, using only elementary techniques, that in addition to giving another example of such a map it is possible to construct the map so as to get another well-known contractible noncollapsible 2-complex as the end result.

THEOREM. *There exists a 3-manifold M with nonempty boundary and a 1-1 continuous map f taking M onto E^3 such that the 1-point compactification of $f(\text{Bd } M)$ is the contractible noncollapsible 2-complex R, known as Bing's house with two rooms.*



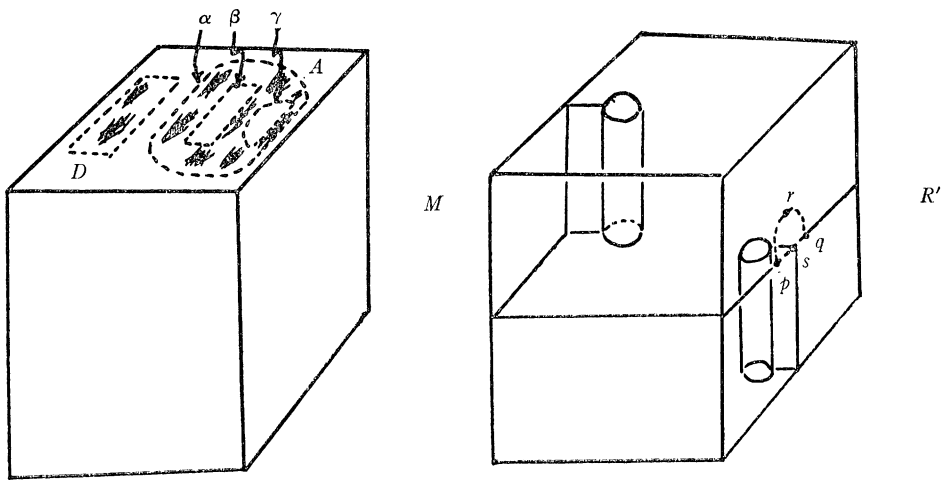


FIG. 1

The contractible noncollapsible 2-complex R, due to R. H. Bing, is most easily described by showing a picture of this 2-polyhedron. This is done in Figure 1. We see in Figure 1, that N is a square disk with an open circular disk removed, S_1 is a square disk with two open circular disks removed, O is a square disk with an open circular disk removed, H_1, H_2, E and G are square disks, I and U are right circular cylinders, and B and S_2 are rectangular disks.

The 3-manifold M with nonempty boundary that we map 1-1 continuously onto an open subset V of E^3 homeomorphic to E^3 will be made up of the interior of the unit 3-cell plus an open disk D and an open two-holed annulus A on the top face of this 3-cell. The 1-1 continuous map f can be most easily described by indicating how we could deform M topologically in E^3 so as to obtain a set V which is topologically E^3.

(i) FIG. 2 (ii)

M is indicated in Figure 2 (i). By first pushing the annulus A down slightly and then pulling up a neighborhood of part of A and expanding, and also pulling up and deforming a neighborhood of D we can deform M into M' as indicated in Figure 3 (the illustration of Figure 3 was suggested to the author by the referee; although it is slightly more complicated than the original version, it does suggest the final deformation more clearly).

We now push the two rectangular disks $abcd$ and $a'b'c'd'$ together so as to form a circular tunnel in the right top part of M'. Then the right top part of M' is pushed down so that the rectangle $efgh$ is matched up with the outer boundary α of the open annulus A (α is also indicated by $e'f'g'h'$). This leaves the bottom section hollow except for a solid circular tube joining the top and bottom faces of this hollow part. We will use the circular tunnel of the right top section to enter this hollow part with the neighborhood T of D. The outer left portion of M' is then pushed against the part of A bounding the right top section of M' so that this section is completely covered with $p'r'q'$ (indicated by the heavy lines) matched up with prq and so that T can be inserted into the circular tunnel and the hollow part formed above. Finally T is expanded so as to fill this part. During this expansion D is pulled around the solid tube so that $u's'v'w'$ matches $usvw$.

We now have the set V which is just a deformed solid open ball which is homeomorphic to E^3. The boundary of $M=D\cup A$ now lies in V as is shown in Figure 2 (ii). This is exactly the 2-polyhedron R except for a closed semi-circular disk $psqr$ removed. The 1-point compactification of $f(\text{Bd } M)$ then closes this part up and we get precisely R.

MATHEMATICAL NOTES

THE DIRECT PRODUCT OF RIGHT ZERO SEMIGROUPS AND CERTAIN GROUPOIDS

R. J. WARNE, West Virginia University

1. Introduction. An M-groupoid S is a groupoid [4] which satisfies the following conditions:

P.1.1. S contains a left identity.

P.1.2. If y or z is a left identity of S, then $(xy)z=x(yz)$ for all x in S.

P.1.3. For any x in S, there is a unique left identity e (which may depend on x) such that $xe=x$.

Such systems were investigated by Tamura, Merkel and Latimer in [2]. According to their results, an M-groupoid S is the direct product of a right zero semi-group, i.e. a semigroup such that $xy=y$ for x, y and a groupoid with identity and conversely.

We will investigate first the structure of semigroups which are direct products of right zero semigroups and cancellative semigroups with identity. We consider the relationship of these semigroups to right groups (the direct products of groups and right zero semigroups). Finally, we consider groupoids which are direct products of right singular semigroups and unipotent (one-idempotent) groupoids with identity.

We will follow the notation and terminology of Clifford and Preston [1] for all concepts not defined in this paper.

2. Left cancellative semigroups and right groups. A decomposition of a groupoid S is a partition of S, $S=U(S_a: a \text{ in } A)$, $S_a \cap S_b=\square$, $a\neq b$ in which for every a, b in A, there is a c in A such that $S_aS_b\subseteq S_c$ [2, p. 118]. If for every such a, b, $c=b$, and each S_a is a groupoid of type T, we say S is a right zero band of groupoids of type T. Semigroups which are "bands of semigroups of type T" have been studied extensively [1]. A right group [1, p. 37] is a semigroup S such that if a, b in S there exists a unique x in S such that $ax=b$. We refer the reader to [1] for references on right groups. An M-groupoid which is a semigroup is called an M-semigroup.

We now give a different formulation of a lemma stated in [2].

LEMMA 1 [2, p. 118]. *A groupoid (semigroup) S is isomorphic to the direct product of two groupoids (semigroups) A and B if and only if there exists homomorphisms U and V of S onto A and B respectively such that for a in A and b in B, $aU^{-1}\cap bV^{-1}=(x_{ab})$, a set consisting of exactly one element. In this case U and V are said to be orthogonal.*

Proof. If x in $aU^{-1}\cap bV^{-1}$, let $xW=(a, b)$. It is easily seen that W is the required isomorphism. The converse is clear.

For the purpose of illustrating this important principle of "orthogonality of decompositions" [2], we will give a proof of the following result established in [2]. Our proof using Lemma 1, is slightly different from that given in [2].

THEOREM 1 [2, p. 119]. *An M-groupoid (semigroup) S is the direct product of a right zero semigroup and a groupoid (semigroup) with identity and conversely. The groupoid (semigroup) with identity is obtained as Se, where e is a left identity.*

Proof. We first show that if e is a left identity of S, Se is a groupoid with identity e. If se, te in Se,

$$(se)(te) = ((se)t)e \quad \text{in } Se \quad \text{and} \quad (se)e = s(ee) = se.$$

Let R denote the subset of left identities of S. Clearly, R is a right zero semigroup. If x in S, let e_x denote the unique left identity of P.1.3. Let $xU=xe$ and $xV=e_x$ for x in S. Since $(xe)(ye)=x(e(ye))=x(ye)=(xy)e$, U is a homomorphism of S onto Se. Since $(xy)e_{xy}=xy=x(ye_y)=(xy)e_y$,

$$e_{xy} = e_y \quad \text{and} \quad e_{xy} = e_x e_y.$$

If e in R, $e=e_e$. Thus, V is a homomorphism of S onto R. Let xe and g be arbitrary elements of Se and R respectively. If $zU=xe$ and $zV=g$, i.e. $ze=xe$ and $zg=z$, then

$$z = zg = z(eg) = (ze)g = (xe)g = x(eg) = xg.$$

However, $(xg)e=x(ge)=xe$ and $(xg)g=xg$. Thus, U and V are orthogonal and $S=RxSe$ by Lemma 1. The converse follows by routine calculation.

THEOREM 2. *The following conditions on a semigroup S are equivalent.*

(1) *S is left cancellative; $ba=ca$ implies $bx=cx$ for all x in S: a in aS for every a in S.*
(2) *$S=E\times C$ where E is a right zero semigroup and C is a cancellative semigroup with identity.*
(3) *S is a right zero band of cancellative semigroups with identity.*

Proof. (1)$\rightarrow$(2): We first show that S is an M-semigroup. Let E denote the set of idempotents of S. If a in S, there exists e in S such that $a=ae$. Hence $ae=ae^2$, $e^2=e$, and e in E, i.e. $E\neq\square$. If e in E and a in S,

$$ea = e^2a = e(ea), \quad \text{and} \quad ea = a.$$

Thus, every idempotent is a left identity. Next, let g be a fixed element of E, and let us consider Sg. Clearly, Sg is left cancellative. Suppose that $(ug)(sg) = (vg)(sg)$ with s, u, v in S. Thus, $ug = (ug)g = (vg)g = vg$ and Sg is cancellative. Apply Theorem 1.

(2)$\rightarrow$(3) For g in E, let $S_g = ((g, c) : c \text{ in } C)$. Clearly, S_g is a cancellative semigroup with identity $(g, 1)$ where 1 is the identity of C and S is a right zero band of the S_g.

(3)$\rightarrow$(1). Let S be a right zero band of the semigroups $(S_t : t \text{ in } T)$ where S_t is a cancellative semigroup with identity e_t. If x in S_t, y in S_w, and a in S_u where t, u, w in T and $ax = ay$, then $w = t$ and $a(e_t x) = a(e_t y)$. Thus, $(ae_t)x = (ae_t)y$ and $x = y$ since x, y, and ae_t in S_t. Hence, S is left cancellative. If $xa = ya$, $x(e_u a) = y(e_u a)$, $(xe_u)a = (ye_u)a$, and $xe_u = ye_u$. If z in S_v (v in T),

$$e_u z = (e_u e_u)z = e_u(e_u z) \quad \text{and} \quad z = e_u z.$$

Thus, $xz = x(e_u z) = (xe_u)z = (ye_u)z = y(e_u z) = yz$.

COROLLARY 1. *The following assertions concerning a semigroup are equivalent.*

(1) *S is a right group.*

(2) *$S = G \times E$ where G is a group and E is a right zero semigroup.*

(3) *S is a right zero band of groups.*

Proof. (1)$\rightarrow$(2). If $ba = ca$ (a, b, c in S) and x in S choose y in S such that $ay = x$. Thus, $bay = cay$ and $bx = cx$. Similarly, a in aS. Thus, by Theorem 2, $S = C \times E$ where C is a cancellative semigroup with identity 1 and E is a right zero semigroup. Thus, if (a, h), $(1, h)$ in $C \times E$, there exists (b, t) in $C \times E$ such that $(a, h)(b, t) = (1, h)$, i.e. $ab = 1$.

(2)$\rightarrow$(3). The proof is similar to the proof "(2)$\rightarrow$(3)" in Theorem 2.

(3)$\rightarrow$(1). Suppose S is the right zero band of groups $(S_a : a \text{ in } A)$. If x in S_a, y in S_b(a, b in A), xy and y in S_b and hence there exists z in S_b such that $x(yz) = (xy)z = y$. S is left cancellative by Theorem 2.

The equivalence of (1) and (2) is given by [1, Theorem 1.27, p. 38].

3. M-groupoids. A groupoid is called unipotent (one-idempotent) if it contains precisely one idempotent [1]. An idempotent e of a groupoid S is said to be primitive if f is an idempotent of S such that $ef = fe = f$, then $e = f$. Primitive idempotents have played an important role in algebra (see [1], for example).

In [3], a groupoid S is said to satisfy VIII$_3'$ (notation of [3]) if it verifies the following conditions:

P.3.1. Existence of a left identity.

P.3.2. $(xy)z = x(yz)$ if y or z is a left identity.

P.3.3. If e, f are idempotents, $ef = f$.

P.3.4. There is a decomposition $(S_a : a \text{ in } A)$ of S such that S_a is a groupoid with two-sided identity e_a.

We will say that a groupoid S satisfies VIII$_2'$ (notation of [3]) if P.3.1, P.3.2, P.3.4 hold and if S verifies

P.(3.3)'. If a, b in A, $e_a e_b = e_b$.

THEOREM 3. VIII$_2'$ *characterizes an M-groupoid* [3].

Proof. For the proof of sufficiency, we may show that VIII$_2'$, implies P.1.3. If e is a left identity of S, e in S_a for some a in A and hence $e=e_a$. Next, we show that each e_a is a left identity of S. Let e_b be a left identity of S (the existence of such is guaranteed by P.3.1). If x is an arbitrary element of S,

$$e_a x = e_a(e_b x) = (e_a e_b)x = e_b x = x.$$

If x in S_a, say, $xe_a=x$. If $xe_c=x$ with $c\neq a$, $S_aS_c\subseteq S_a$ and $e_c=e_ae_c$ in S_a, a contradiction. Thus, $e_c=e_a$ and P.1.3 is valid.

To prove necessity, we note that S is the direct product of a right zero semigroup E and a groupoid G with identity 1 by Theorem 1. If for e in E, we let $S_e=((e, g): g \text{ in } G)$, (S_e) is a decomposition of S such that each S_e is a groupoid with identity $(e, 1)$. The collection of left identities is $((e, 1): e \text{ in } E)$. It is now a routine calculation to establish P.(3.3)$'$.

THEOREM 4. *The following conditions on a groupoid are equivalent.*

(1) *S is an M-groupoid such that each left identity is a primitive idempotent.*
(2) *$S=E\times G$ where E is a right zero semigroup and G is an unipotent groupoid with identity.*
(3) *S satisfies* P.1.1 *and* P.1.2 *and S is a right zero band of unipotent groupoids with identity.*
(4) *S satisfies* VIII$_3'$.

Proof. (1)$\rightarrow$(2). Let e be a left identity of S and suppose that g is an idempotent of Se. Then, $g=xe$ for some x in S, $ge=(xe)e=x(ee)=xe=g$, and $e=g$. Apply Theorem 1.

(2)$\rightarrow$(3). It is easy to see that $((e, 1): e \text{ in } E)$, where 1 is the identity of G, is both the collection of idempotents and the collection of left identities of $E\times G$. P.1.2 is verified by routine calculation. If $S_e=((e, g): g \text{ in } G)$, S is a right zero band of the (S_e) and each S_e is clearly a unipotent groupoid with identity.

(3)$\rightarrow$(4). Clearly, P.3.1, P.3.2, and P.3.4 are valid. Let S be the right zero band $(S_a: a \text{ in } A)$ of unipotent groupoids with identity e_a.

Clearly $(e_a: a \text{ in } A)$ is the collection of idempotents of S. Let e_a be a left identity of S and suppose e_b is an arbitrary idempotent of S.

If $e_be_a=z$ in S_a, $e_bz=e_b(e_be_a)=e_be_a=z$ and $z^2=(e_be_a)z=e_b(e_az)=e_bz=z$, i.e. $e_be_a=e_a$. If c in A, $e_be_c=e_b(e_ae_c)=(e_be_a)e_c=e_ae_c=e_c$ and P.3.3 is verified.

(4)$\rightarrow$(1). Clearly, VIII$_3'$ implies VIII$_2'$. Thus, S is an M-groupoid by Theorem 3. If e and f are idempotents and $ef=fe=f$, then $e=f$ by P.3.3.

If the semigroup S is the right zero band $(S_a: a \text{ in } A)$ of unipotent semigroups with identity e_a,

$$(e_ae_b)(e_ae_b) = e_a(e_b(e_ae_b)) = e_a(e_ae_b) = e_ae_b \quad \text{and} \quad e_ae_b = e_b(a, b \text{ in } A).$$

If x in S_c, say, $e_ax=e_a(e_cx)=(e_ae_c)x=e_cx=x$ and e_a is a left identity. Thus, the modification of Theorem 4 to semigroups is clear.

We next give the analogue of Theorem 2 for groupoids.

THEOREM 5. *The following assertions on a groupoid are equivalent.*

(1) *S satisfies* P.1.1 *and* P.1.2. *S is left cancellative; $ba=ca$ implies $bx=cx$ for all x in S; if a in S there exists a left identity e such that $a=ae$.*

(2) *$S=E\times C$ where E is a right zero semigroup and C is a cancellative groupoid with identity.*

(3) *S satisfies* P.1.1 *and* P.1.2 *and S is a right zero band of cancellative groupoids with identity.*

Proof. (1)→(2). Clearly, S is an M-groupoid. If g is a left identity of S, we show as in the proof of "(1)→(2)" in Theorem 2, that Sg is cancellative. Apply Theorem 1.

(2)→(3). Since C is unipotent, we proceed as in the proof of "(2)→(3)" in Theorem 4.

(3)→(1). Let S be the right zero band of cancellative groupoids with identity $(S_a: a \text{ in } A)$ where e_a is the identity of S_a. By Theorem 4, $e_ae_b=e_b(a, b \text{ in } A)$ and P.1.1, P.1.2, and P.1.3 are valid. As in the proof of Theorem 3, we show each e_a is a left identity of S. Thus, we may proceed as in the proof of "(3)→(1)" in Theorem 2.

For a fairly complete bibliography on the theory of groupoids, see [4].

ON THE STRUCTURE OF J-RINGS

JIANG LUH, Indiana State University

1. Introduction. A ring R is called a J-ring if there exists an integer $n>1$ such that $x^n=x$ for every $x\in R$. It is well known that every J-ring is commutative (cf. [2] p. 217).

Raymond and Christine Ayoub [1] have recently proved this theorem for a certain class of exponents n without recourse to transfinite methods. In their paper, it also has been proved that every J-ring is a direct sum of rings with prime characteristic. The purpose of this note is to investigate further properties of these direct summands and to obtain the structure of J-rings.

In the sense of McCoy and Montgomery [4], a ring R is called a p^k-ring if there exist a prime p and a positive integer k such that $x^{p^k}=x$ and $px=0$ for every x in R. A p-ring is simply a p^1-ring.

In the present note, we shall prove the following

MAIN THEOREM. *A ring R is a J-ring if and only if R is a direct sum of finitely many p^k-rings.*

2. Preliminaries. The following important theorem which is proved in [3] will be used in the following proofs.

THEOREM 1 (DIRICHLET). *If $a>0$ and b are integers and if $(a, b)=1$, then there are infinitely many primes of the form $an+b$, where n is a positive integer.*

THEOREM 2. *If $m_1, m_2, \cdots, m_r$ are positive integers $\geqq 2$, then there exists a prime p such that*

$$m_i - 1 \mid p - 1, \quad i = 1, 2, \cdots, r.$$

Proof. Let $a=(m_1-1)(m_2-1)\cdots(m_r-1)$ and let $b=1$. By Theorem 1, there exists a prime

$$p = (m_1 - 1)(m_2 - 1)\cdots(m_r - 1)n + 1$$

for some positive integer n. Thus, $m_i-1 \mid p-1$, $i=1, 2, \cdots, r$.

THEOREM 3. *If n is an arbitrary integer >1 and if q is prime, then there exist integers $k\geqq 1$ and $t\geqq 0$ such that $q^t(q^k-1)\equiv 0 \pmod{n-1}$.*

Proof. Write $n-1=mq^t$, where $q \nmid m$. By the Fermat-Euler Theorem, $q^k\equiv 1 \pmod{m}$, or $m \mid q^k-1$, where $k=\phi(m)$, so that $n-1 \mid q^t(q^k-1)$.

THEOREM 4. *If x is an element of a ring R such that $x^n=x$ for some integer $n>1$ and if h and k are positive integers, $h\equiv k \pmod{n-1}$, then $x^h=x^k$.*

This result can be easily obtained by induction (cf. [1]).

We can now give a characterization of J-rings.

THEOREM 5. *A ring R is a J-ring if and only if there exists a prime p such that $x^p=x$ for every x in R.*

Proof. Sufficiency: Obvious.

Necessity. Suppose that $x^n=x$ for every $x\in R$. By Theorem 2, a prime p exists such that $n-1 \mid p-1$, or $p\equiv 1 \pmod{n-1}$. By applying Theorem 4, we have $x^p=x$ for every x in R.

3. Proof of the Main Theorem. First, let us assume that R is a direct sum of finitely many $p(i)^{k(i)}$-rings R_i, say, $R=R_1\oplus R_2\oplus \cdots \oplus R_r$. Hence, by Theorems 2 and 4, there exists a prime p such that for any $x=(x_1, x_2, \cdots, x_r)\in R$ with $x_i\in R_i$, $x^p=(x_1^p, x_2^p, \cdots, x_r^p)=(x_1, x_2, \cdots, x_r)=x$. Therefore, R is a J-ring.

Conversely, suppose that R is a J-ring and that $x^n=x$ for every $x\in R$. We shall show that R is a direct sum of finitely many $p(i)^{k(i)}$-rings.

Since $(ax)^n=ax$, or $(a^n-a)x=0$ for every $x\in R$ and every integer a, there exists a least positive integer m such that $mx=0$ for every x in R. Clearly,

$m \mid a^n - a$, for every integer a. We claim now that m is a product of distinct primes. To see this, it will be sufficient to show that if $m = p_1 m_1$, where p_1 is a prime factor of m, then $(p_1, m_1) = 1$. Indeed, suppose contrarily that $m_1 = p_1 m_2$ for some integer m_2. Then, for every $x \in R$,

$$m_1 x = (m_1 x)^n = m_1^n x = p_1^n m_2^n x = p_1^{n-2} m_2^{n-1} mx = 0,$$

which contradicts the choice of m. Thus, $m = p(1) \cdot p(2) \cdot \cdots \cdot p(r)$, where $p(i)$ are distinct primes. Set

$$R_i = \{x \in R: p(i)x = 0\}, \quad i = 1, 2, \cdots, r.$$

Evidently, R_i is a subring of R with characteristic $p(i)$ and $R = R_1 \oplus \cdots \oplus R_r$.

Now we are in a position to finish the proof of the main theorem by showing that each R_i is a $p(i)^{k(i)}$-ring. In fact, by Theorem 3, there exist integers $t(i) \geqq 0$ and $k(i) \geqq 1$ such that $n-1 \mid p(i)^{t(i)}(p(i)^{k(i)} - 1)$. Hence, for every $x \in R$, we have

$$(x - x^{p(i)^{k(i)}})^{p(i)^{t(i)}} = x^{p(i)^{t(i)}} - x^{p(i)^{k(i)+t(i)}} = 0,$$

the last equality being a consequence of Theorem 4. But R has no nilpotent element other than 0. Therefore, we obtain that

$$x - x^{p(i)^{k(i)}} = 0, \quad \text{or} \quad x^{p(i)^{k(i)}} = x.$$

Thus, R_i is a $p(i)^{k(i)}$-ring.

REMARK. In view of the main theorem, we can reduce the proof of commutativity of J-rings to consider only p^k-rings.

The author is now at The Wright State University, Dayton, Ohio.

ON STRONGLY CONTINUOUS FUNCTIONS

S. A. NAIMPALLY, Iowa State University (Now at University of Alberta, Edmonton, Canada)

Let X and Y be topological spaces. Levine [2] defined a function $f: X \to Y$ to be *strongly continuous* iff for each subset K of X, $f(\overline{K}) \subset f(K)$. When Y is a uniform space the function space of continuous functions on X to Y is closed in Y^X in the topology of uniform convergence. It is natural to enquire whether a similar result is true for the function space of strongly continuous functions. This investigation resulted in a surprise: namely, that with some restrictions on X and Y the function space of strongly continuous functions is even closed in the pointwise convergence topology! It is well known that a similar result is not true for the function space of continuous functions.

In what follows S will denote the set of all strongly continuous functions on X to Y and will be assigned the pointwise convergence (or p.c.) topology. (See Kelley [1] page 217.)

The following results which are proved by Levine in [2] are recorded here to make the note self-contained.

(a) If $f\in S$ and K is a nonempty connected subset of X, then $f(K)$ is a single point.

(b) If X is locally connected and f is a function on X to Y such that for each nonempty connected subset K of X $f(K)$ is a single point, then $f\in S$.

1. THEOREM. *Let Y be Hausdorff and $f\in\overline{S}$ (the bar denotes closure in the p.c. topology). Then for each nonempty connected subset K of X, $f(K)$ is a single point.*

Proof. Suppose that there exists a nonempty connected subset K of X such that $f(K)$ contains at least two distinct points $f(p)$ and $f(q)$. Since Y is Hausdorff $f(p)$ and $f(q)$ have disjoint open neighborhoods U and V respectively. Since $f\in\overline{S}$, there exists a net $\{f_n \mid n\in D\}\subset S$ such that for each $x\in X$, $f_n(x)\to f(x)$. So there exists an $m\in D$ such that for all $n\geqq m$, $f_n(p)\in U$ and $f_n(q)\in V$. This contradicts (a) and the theorem is proved.

The following example shows that the hypothesis of Theorem 1 cannot be weakened.

2. *Example.* Let X consist of two points p, q with the topology consisting of $\varnothing$, $\{p\}$, X. Let Y be the set of integers with cofinite topology. It is well known that Y is T_1 but not Hausdorff. Since X is connected all the elements of S are constant functions. If $f\in Y^X$ and $f\notin S$ then $f(p)=m$, $f(q)=n$, $m\neq n$. A neighborhood of f in the p.c. topology is of the form $\{g\in Y^X \mid g(p)\in U \text{ and } g(q)\in V\}$, where U and V are open sets in Y containing m and n respectively. But $U\cap V\neq\varnothing$ for each pair of open sets U, V of Y. Let $r\in U\cap V$. Let $h(p)=h(q)=r$. Then h belongs to the above neighborhood of f and so $f\in\overline{S}$, but f does not take the connected set X into a single point.

Theorem 1 combined with (b) lead to the following result.

3. THEOREM. *If X is locally connected and Y Hausdorff then S is closed in Y^X in the p.c. topology.*

The above Example 2 shows that if X is locally connected and Y is not Hausdorff then the above Theorem 3 is false. The following example shows that X must be locally connected.

4. *Example.* Let $X=\{0,\ 1/n\}$, $n=1,\ 2,\ 3,\ \cdots$ with the usual subspace topology of the reals. Let Y be the reals with the usual topology. Let $f_n\in Y^X$ be defined as

$$f_n(0)=1, \qquad f_n\left(\frac{1}{m}\right)=\begin{cases}\dfrac{1}{m} & \text{for } m<n\\ 1 & \text{for } m\geqq n.\end{cases}$$

Then each $f_n \in S$ and $f_n \to f$, where

$$f(0) = 1, \qquad f\left(\frac{1}{m}\right) = \frac{1}{m} \quad m = 1, 2, 3, \cdots.$$

Clearly f is not even continuous, although f is a pointwise limit of $\{f_n\}$ a sequence of strongly continuous functions.

It is well known that if Y is compact then the space of all continuous functions on X to Y need not be compact even in the topology of uniform convergence. In contrast to this we have the following result for S.

5. THEOREM. *If X is locally connected and Y compact Hausdorff, then S is compact in the p.c. topology.*

Proof. By Theorem 3, S is pointwise closed in Y^X. Also since Y is compact, for each $x \in X$, $S(x) = \{f(x) \mid f \in S\}$ has compact closure in Y. These are the two properties of the hypotheses of Theorem 1 page 218 of Kelley [1], from which it follows that S is compact in the p.c. topology.

6. THEOREM. *If X is locally connected and Y a uniform space with a uniformity $\mathcal{U}$ then S is equicontinuous (i.e. for each $x \in X$ and $V \in \mathcal{U}$ there exists a neighborhood U of x such that $f(U) \subset V[f(x)]$ for all $f \in S$).*

Proof. For each $x \in X$ there exists an open connected neighborhood U of x and so for all $f \in S$, $f(U) = f(x)$. So obviously $f(U) \subset V[f(x)]$ for all $V \in \mathcal{U}$ and $f \in S$. Thus S is equicontinuous.

For the function space of all continuous functions on X to Y, the p.c. topology is not satisfactory and so we use the topology of uniform convergence on compacta (when Y is a uniform space). Theorem 3 has already shown that the p.c. topology is quite adequate for S when X is locally connected and Y Hausdorff. The following theorem which follows easily from Theorem 6 above and Theorem 15 of Kelley [1] page 232, shows that the two topologies are in fact equivalent for S.

7. THEOREM. *If X is locally connected and Y a uniform space then the p.c. topology for S coincides with the topology of uniform convergence on compacta. Consequently, S is evenly continuous (i.e. for each $x \in X$, each $y \in Y$ and each neighborhood U of y there exists a neighborhood V of x and a neighborhood W of y such that $f(V) \subset U$ whenever $f(x) \in W$).*

The author would like to thank Prof. D. E. Sanderson and the referee for their comments and suggestions.

MAXIMAL NON-T_i SPACES, $i=0,1,2,3$

J. P. THOMAS, University of North Carolina at Charlotte

It is the purpose of this paper to investigate the existence and characteristics of maximal non-Kolmogoroff, (non-T_0), maximal nonaccessible, (non-T_1), maximal nonseparated (non-Hausdorff or non-T_2) and maximal nonregular (non-T_3) topological spaces. (T_i is here to be understood in the sense of Kelley [2].) In general, terminology and notation will be that of N. Bourbaki [1]. The notation $(X, \mathfrak{I})$ will denote a set X with topology $\mathfrak{I}$. A topology $\mathfrak{I}$ will be said to be finer than $\mathfrak{I}'$ if $\mathfrak{I}' \subset \mathfrak{I}$. If A is a set of subsets of X we shall denote by $\Phi(A)$ the topology generated by A.

DEFINITION I. *A topological space $(X, \mathfrak{I})$ is said to be maximal non-Kolmogoroff (resp. maximal nonaccessible, maximal nonseparated, maximal nonregular) if it is not a Kolmogoroff (resp. accessible, separated, regular) space and if any strictly finer topology on X is Kolmogoroff (resp. accessible, separated, regular).*

If a set X has at least two elements, say a, b, then

$$\mathfrak{I}_1 = \Phi(\{\{a, b\}\} \cup \{\{x\} \mid x \in X, x \neq a, b\})$$

is maximal non-Kolmogoroff and $\mathfrak{I}_2 = \Phi(\{\{a, b\}\} \cup \{\{x\} \mid x \in X, x \neq a\}$ is maximal nonaccessible, maximal nonseparated and maximal nonregular. It is easy to see that any maximal non-Kolmogoroff (resp. maximal nonaccessible) topology is of the form of $\mathfrak{I}_1$ (resp. $\mathfrak{I}_2$) and that any non-Kolmogoroff (resp. nonaccessible) topology is coarser than a maximal non-Kolmogoroff (resp. nonaccessible) topology. The problem is more difficult in the case of nonseparated and nonregular topologies.

THEOREM I. *Let X be any set and let $\mathfrak{I}_1$ be a nonseparated topology on X. Then there exists a maximal nonseparated and maximal nonregular topology $\mathfrak{I}_2$ on X which is finer than $\mathfrak{I}_1$.*

Proof. If $\mathfrak{I}_1$ is nonaccessible it has already been remarked that there exists a topology of the form $\Phi(\{\{a, b\}\} \cup \{\{x\} \mid x \in X, x \neq a\})$ where $a \neq b$ which is finer than $\mathfrak{I}_1$. Such a topology is maximal nonseparated and maximal nonregular. Hence, suppose that $\mathfrak{I}_1$ is accessible. Since $\mathfrak{I}_1$ is nonseparated there exists an ultrafilter $\mathfrak{U}$ on $(X, \mathfrak{I}_1)$ with two distinct limit points, say a and b. Let $\mathfrak{I}_2 = \Phi(\mathfrak{U} \cup \{\{x\} \mid x \in X, x \neq a, b\}$. Clearly $\mathfrak{I}_2$ is finer than $\mathfrak{I}_1$ and is non-separated (and hence non-regular) since neighborhoods of a and b always intersect. $\mathfrak{I}_2$ is maximal nonseparated. For, if $\mathfrak{I}_3$ is strictly finer than $\mathfrak{I}_2$ let $A \in \mathfrak{I}_3 \cap C\mathfrak{I}_2$. Then $a \in A$ or $b \in A$ for otherwise $A \in \mathfrak{I}_2$. Suppose that $a \in A$ but $b \notin A$. Since $A \notin \mathfrak{U}$ we have $CA \in \mathfrak{U} \subset \mathfrak{I}_2$. Thus A and CA are disjoint $\mathfrak{I}_3$ neighborhoods of a and b respectively. If $c \neq a$, b there is a neighborhood V of a which does not contain c since $\mathfrak{I}_1$ is accessible. Then V and $\{c\}$ are disjoint neighborhoods of a and c respectively. Similarly we can find disjoint neighborhoods of b and c. Thus in this case $\mathfrak{I}_3$ is separated. In case $a, b \in A$, since $A \notin \mathfrak{U}$ we have $CA \in \mathfrak{U} \subset \mathfrak{I}_3$. Then

$CA \cup \{a\} \in \mathfrak{U} \subset \mathfrak{I}_3$ and $\{a\} = A \cap (CA \cup \{a\}) \in \mathfrak{I}_3$. Similarly $\{b\} \in \mathfrak{I}_3$ and thus $\mathfrak{I}_3$ is discrete and therefore separated.

Finally we find that $\mathfrak{I}_3$ is regular. For if $c \in X$, $c \neq a$, b then c has a fundamental system of closed neighborhoods since c is isolated and $\mathfrak{I}_3$ is separated. Now let V be any neighborhood of b. Let W_1 and W_2 be disjoint neighborhoods of a and b respectively. Then $W_2 \cap V$ is a neighborhood of b and is contained in V and is closed since

$$C(W_2 \cap V) = W_1 \bigcup_{x \in C(W_1 \cup (W_2 \cap V))} \{x\}$$

is open

THEOREM 2. *Let $(X, \mathfrak{I}_1)$ be a separated nonregular topological space. Then there exists a topology $\mathfrak{I}_2$ on X which is separated, nonregular and strictly finer than $\mathfrak{I}_1$.*

Proof. There exist $x \in X$, $V \in \mathfrak{I}_1$ such that $x \in V$ and such that if Y is a neighborhoog of x then $\overline{Y} \cap CV \neq \phi$. Suppose that $x \in W \subset V$, $W \in \mathfrak{I}_1$. We shall show that $\overline{W} \cap CV$ is infinite. For suppose that $\overline{W} \cap CV = \{v_1, v_2, \cdots, v_n\}$ with n finite. Then there exist neighborhoods $V_1, V_2, \cdots, V_n$ of $v_1, v_2, \cdots, v_n$ respectively and neighborhoods $W_1, W_2, \cdots, W_n$ of x, such that $W_i \cap V_i = \phi$, $i = 1, 2, \cdots, n$. Then $W' = W \cap W_1 \cap \cdots \cap W_n \subset W$ is a neighborhood of x. We shall show that $\overline{W}' \subset V$ which will be a contradiction. For let $v \in \overline{W}' \cap CV$. Then $v = v_i$ for some $v_i \in \overline{W} \cap CV$ since $W' \subset W$. But V_i is a neighborhood of v which does not intersect W'. Now let $z \in \overline{V} \cap CV$ and note that z is not isolated for $\mathfrak{I}_1$. Define $\mathfrak{I}_2 = \Phi(\mathfrak{I}_1 \cup \{\{z\}\})$. Then $\mathfrak{I}_2$ is strictly finer than $\mathfrak{I}_1$ and is separated since $\mathfrak{I}_1$ is separated. And $\mathfrak{I}_2$ is nonregular, for if U is an open neighborhood of x for $\mathfrak{I}_2$ and $U \subset V$, then $\overline{U} \cap CV$ is infinite for $\mathfrak{I}_1$ by the above argument and is therefore infinite for $\mathfrak{I}_2$, since all points except z have the same neighborhoods as for $\mathfrak{I}_1$.

COROLLARY I. *There exist no separated maximal nonregular topologies.*

Proof-Trivial.

COROLLARY 2. *Let X be any set. Then the maximal nonseparated topologies are the maximal nonregular topologies on X.*

Proof. Let $\mathfrak{I}_1$ be a maximal nonseparated topology on X. By Theorem I there exists a maximal nonseparated, maximal nonregular topology $\mathfrak{I}_2$ on X which is finer than $\mathfrak{I}_1$. But this implies $\mathfrak{I}_1 = \mathfrak{I}_2$.

Let $\mathfrak{I}_3$ be a maximal nonregular topology on X. By Corollary I, $\mathfrak{I}_3$ is nonseparated. Hence by Theorem I there exists a maximal nonseparated, maximal nonregular topology $\mathfrak{I}_4$ on X such that $\mathfrak{I}_4$ is finer than $\mathfrak{I}_3$. But since $\mathfrak{I}_3$ is maximal nonregular this implies that $\mathfrak{I}_3 = \mathfrak{I}_4$.

THEOREM 3. *Let X_1 and X_2 be topological spaces, each having more than one element. Then $X_1 \times X_2$ with the product topology is neither maximal non-Kolmogoroff, maximal nonaccessible, nor maximal nonseparated.*

Proof. Let $\mathfrak{I}$ be the product topology on $X_1 \times X_2$. If both X_1 and X_2 are Kolmogoroff, $(X_1 \times X_2, \mathfrak{I})$ is Kolmogoroff, so assume X_1 is non-Kolmogoroff. There exist $a, b \in X$, $a \neq b$ such that $a \in \overline{\{b\}}$, $b \in \overline{\{a\}}$. Let $c, d \in X_2$. Then $(b, c) \in \overline{\{(a, c)\}}$, $(a, c) \in \overline{\{(b, c)\}}$, $(b, d) \in \overline{\{(a, d)\}}$ and $(a, d) \in \overline{\{(b, d)\}}$. Thus $(X_1 \times X_2, \mathfrak{I})$ is not maximal non-Kolmogoroff. The proof for nonaccessible and nonseparated spaces is similar.

The author is grateful to Dr. E. E. Enochs for supervision in the preparation of this paper.

REMARKS ON DETECTION PROBLEMS

PETER FRANK AND ROBERT SILVERMAN, Syracuse University

Given a finite set $S = \{a_1, a_2, \cdots, a_n\}$, denote by 2^S the class of all subsets of S, and by $|X|$ the number of elements in the set X. For X, Y in 2^S, define $d(X, Y) = |X \triangle Y|$, where $X \triangle Y = (X \cup Y) - (X \cap Y)$. Thus the "distance" between the sets X and Y is the number of elements in their symmetric difference. One readily verifies that d is a metric on 2^S. The structure of the metric space of 2^S is intimately connected with many of the basic problems in combinatorics [3].

The sets $R_1, \cdots, R_k$ are termed a *metric basis* of 2^S provided that $|X \triangle R_i| = |Y \triangle R_i|$, $i = 1, \cdots, k$ implies that $X = Y$. A metric basis is *minimal* provided no other metric basis has fewer elements. Denote by $F(n)$ the number of elements in a minimal basis.

One may also look for sets $R_1, \cdots, R_k$ such that $|R_i \cap X| = |R_i \cap Y|$, $i = 1, \cdots, k$ implies that $X = Y$. We call such a family of sets an *intersection detecting* family. Again one may seek the least value of k for which there exists an intersection detecting family with k sets. Denote this value by $f(n)$.

Söderberg and Shapiro [4] considered $f(n)$, and Erdös and Rényi [1] studied both $f(n)$ and $F(n)$. Lindström [2] finally showed that $\lim_{n\to\infty} [f(n) \log n]/n = \log 4$, and by an additional special and somewhat lengthy argument established that also $\lim_{n\to\infty} [F(n) \log n]/n = \log 4$. We show here that either result can be derived from the other, and indeed that $|F(n) - f(n)| \leqq 1$. This follows immediately from the relations

$$(1) \qquad |R \triangle X| + 2|R \cap X| = |R| + |X|,$$

$$(2) \qquad |X| = |Y| \Leftrightarrow |S \cap X| = |S \cap Y| \Leftrightarrow |S \triangle X| = |S \triangle Y|.$$

From (1) we obtain

(3) if $|X| = |Y|$, then $|R \triangle X| = |R \triangle Y| \Leftrightarrow |R \cap X| = |R \cap Y|$.

Combining (2) and (3) we see that

$$|S\cap X| = |S\cap Y| \text{ and } |R_i\cap X| = |R_i\cap Y| \Rightarrow |R_i\triangle X| = |R_i\triangle Y|.$$

Hence if $R_1, \cdots, R_k$ is a metric basis, then $R_1, \cdots, R_k, S$ is an intersection detecting family. Similarly, if $R_1, \cdots, R_k$ is intersection detecting, then $R_1, \cdots, R_k, S$ is a metric basis.

The two problems above may be given matric formulations and indeed, this is the form in which they are treated in the references. Form the "incidence" matrix $A=[a_{ij}]$, where $a_{ij}=1$ if a_j is in R_i, and 0 otherwise. Then $R_1, \cdots, R_k$ is an intersection detecting family if and only if $Ax=Ay\Rightarrow x=y$ for all 0, 1 column vectors x, y. Now obtain the matrix B from A by replacing all 0's in A by -1's. Then $R_1, \cdots, R_k$ is a metric basis if and only if $Bx=By\Rightarrow x=y$ for all 0, 1 column vectors x, y. The latter result is evident if we observe that using (1) together with $|X|-2|R\cap X| = |X-R| - |X\cap R|$, we obtain

$$(4)\quad |R\Delta X| = |R\Delta Y| \Leftrightarrow |X\cap R| - |X-R| = |Y\cap R| - |Y-R|.$$

But $|X\cap R_i| - |X-R_i|$ is precisely the inner product of the ith row of B with the 0, 1 vector corresponding to X.

We now consider more general detection problems. Let $f(R, X)$ denote a Boolean set operation (expressible in terms of intersection and complementation, and thus union). If $f_1, \cdots, f_k$ are k such set operations (distinct or not) we say that $R_1, \cdots, R_k$ is $f_1, \cdots, f_k$ detecting for S provided that $|f_i(R_i, X)| = |f_i(R_i, Y)|$, $i=1, \cdots, k$ implies that $X=Y$. If $f_1, \cdots, f_k$ are all equal to f, we say that $R_1, \cdots, R_k$ is f-detecting for S. We see that $R_1, \cdots, R_k$ is $\triangle$-detecting for S if and only if $R_1, \cdots, R_k$ are a metric basis of 2^S.

There are 16 Boolean set operations. Of these, 6 are of no use for detection purposes: $f(R, X)=\phi$, S, X, X', R, or R', where " $'$ " denotes complementation. This leaves 10, which we now list:

$$\begin{aligned}
T_1(R, X) &= R\cap X & T_6(R, X) &= (R\cap X)'\\
T_2(R, X) &= R'\cap X & T_7(R, X) &= (R'\cap X)'\\
T_3(R, X) &= R\cap X' & T_8(R, X) &= (R\cap X')'\\
T_4(R, X) &= R'\cap X' & T_9(R, X) &= (R'\cap X')' = (R\cup X)\\
T_5(R, X) &= R\triangle X & T_{10}(R, X) &= (R\triangle X)'.
\end{aligned}$$

The following lemma generalizes (3).

LEMMA. *If* $|X| = |Y|$, *then for all* $i, j=1, \cdots, 10$

$$|T_i(R, X)| = |T_i(R, Y)| \Leftrightarrow |T_j(R, X)| = |T_j(R, Y)|.$$

The proof follows from (3) and the following identities:

$$\begin{aligned}
|T_1| + |T_6| &= |T_2| + |T_7| = |T_3| + |T_8| = |T_4| + |T_9|\\
&= |T_5| + |T_{10}| = n
\end{aligned}$$

$$|T_1(R, X)| + |T_2(R, X)| = |X|$$
$$|T_1(R, X)| + |T_3(R, X)| = |R|$$
$$|T_3(R, X)| + |T_4(R, X)| = |X'|.$$

The lemma can be restated as a general theorem about detection, which shows that the most general detection scheme gives an advantage of at most one over the intersection detection scheme.

THEOREM 1. *Let* $f_1, \cdots, f_k, f_1^*, \cdots, f_k^*$ *and* f *be in* $\{T_1, \cdots, T_{10}\}$. *If* $A_1, \cdots, A_k$ *is* $f_1, \cdots, f_k$ *detecting for* S, *then* $A_1, \cdots, A_k, B$ *is* $f_1^*, \cdots, f_k^*, f$ *detecting for* S. *Here* $B = S$ *when* f *is* T_1, T_3, T_5, T_6, T_8 *or* T_{10}, *and* $B = \phi$ *when* f *is* T_2, T_4, T_7 *or* T_9.

As a special case, $f_1^*, \cdots, f_k^*$ can all be taken equal to f.

We conclude by stating a duality theorem.

THEOREM 2. $R_1, \cdots, R_k$ *is* $\cap$*-detecting for* S *if and only if* $R_1', \cdots, R_k'$ *is* $\cup$*-detecting for* S.

The proof follows immediately from the identity $|R' \cup X'| + |R \cap X| = n$.

A NOTE ON NEAR-RINGS OVER VECTOR SPACES

R. E. WILLIAMS, Westminister College

The near-rings considered in this note satisfy the ring axioms with the possible exception of the right distributive law. These are a special class of left near-rings.

The problem of determining the near-rings definable on a finite cyclic group has been considered in this MONTHLY [1] by J. R. Clay with the following result: A necessary and sufficient condition that $(Z_n, +, *)$ be a left near-ring is that there exist a mapping π: $p \to \pi(p)$ of Z_n into Z_n with the properties that:

1. $\pi(p) = p * 1$ for each p,
2. $\pi(p)\pi(q) = \pi(p\pi(q))$ for each p, q.

The addition in the near-ring is the same as that in Z_n and the products $\pi(p)\pi(q)$, $p\pi(q)$ are the usual products in Z_n. A partition of this class of near-rings into isomorphic classes was also obtained.

In this note similar results are established for arbitrary (right) vector spaces. Briefly, (1) is replaced by the condition that the function of p be a linear transformation subject to (2). This gives the following theorem, where V is a right vector space over a division ring D and $\mathfrak{L}$ denotes the complete ring of linear transformations of V.

THEOREM 1. *A necessary and sufficient condition that* $N=(V, +, *)$ *be a near-ring with the usual addition in* V *and such that* $x*(y\alpha)=(x*y)\alpha$, x, y *in* V, α *in* D, *is that there exist a mapping* $L: x\to L(x)$ *of* V *into* $\mathfrak{L}$ *with the properties*:

a. $x*y=yL(x)$, b. $L(y)L(x)=L(yL(x))$,

where $L(x)$ *is the image of* x *in* $\mathfrak{L}$.

Proof. For the necessity, let N be a near-ring such that $(N, +)$ is a right vector space over D. For x in N, denote the mapping $x'\to x*x'$ by $L(x)$. $L(x)$ is linear as

$$(y+z)L(x) = x*(y+z) = x*y + x*z = yL(x) + zL(x),$$
$$(y\alpha)L(x) = x*(y\alpha) = (x*y)\alpha = (yL(x))\alpha,$$

for each y, z in N, α in D. Thus $L(x)$ is in $\mathfrak{L}$ for each x, showing the existence of a mapping $L: x\to L(x)$ of V into $\mathfrak{L}$.

The condition $L(y)L(x)=L(yL(x))$ on L follows from

$$x*(y*z) = (y*z)L(x) = zL(y)L(x) = zL(x*y) = zL(yL(x)).$$

To establish sufficiency, choose $L: x\to L(x)$ such that $L(y)L(x)=L(yL(x))$ and define $x*y=yL(x)$. Clearly

$$x*(y+z) = (y+z)L(x) = yL(x) + zL(x) = x*y + x*z$$

so the product is left distributive. Also, from

$$x*(y*z) = (y*z)L(x) = zL(y)L(x),$$
$$(x*y)*z = zL(x*y) = zL(yL(x)),$$

it follows that the product is associative. Finally, as V is a vector space over D the condition $x*(y\alpha)=(x*y)\alpha$ is valid since $L(x)$ is in $\mathfrak{L}$.

THEOREM 2. *Let* $N_i=(V, +, *_i)$, $i=1, 2$ *be near-rings determined as in Theorem* 1, *by* L^1, L^2. *A necessary and sufficient condition that* N_1 *be isomorphic with* N_2 *with* $(N_1, +)$ *and* $(N_2, +)$ D*-isomorphic is that there exist a nonsingular element* T *in* $\mathfrak{L}$ *such that* $L^1(x)=TL^2(xT)T^{-1}$ *for each* x *in* N.

Proof. Let $L^1(x)=TL^2(xT)T^{-1}$. Clearly $x\to xT$ is a D-isomorphism of $(N_1, +)$ onto $(N_2, +)$. Then

$$(x*_1 y)T = yL^1(x)T = yTL^2(xT)T^{-1}T = (xT)*_2(yT),$$

so the condition is sufficient.

Now let $N_1\approx N_2$ such that $(N_1, +)$ is D-isomorphic with $(N_2, +)$. Considera-

tion of the additive groups shows that the isomorphism is achieved by a non-singular linear transformation $T: N_1 \to N_2$. Thus

$$(x *_1 y)T = yL^1(x)T = (xT) *_2 (yT) = yTL^2(xT),$$

so $yL^1(x) = yTL^2(xT)T^{-1}$ for each x, y in V. Hence the condition is necessary.

In considering the sums $L(x)+L(y)$, it may be verified that $L(x+y)=L(x)+L(y)$ is a sufficient condition for N to be a ring. In any case, it is clear that there is a smallest subring of $\mathfrak{L}$ which contains all of the elements $L(x)$, x in N and hence contains the finite sums, regardless of any condition on L.

DEFINITION. *Let A be the subring of $\mathfrak{L}$ generated by the $L(x)$, x in V. A is called the associated ring of N. The set $[L(x)] = [L(x) \mid x \in V]$ is called the set of generators of A.*

THEOREM 3. *Let $N_i = (V, +, *_i)$, $i=1, 2$ be isomorphic near-rings with D-isomorphic additive groups and let A_1 and A_2 be the associated rings. Then the inner automorphism $a \to a^T = T^{-1}aT$ of $\mathfrak{L}$ induces the isomorphism $A_1 \to A_1^T = A_2$.*

Proof. Let $[L^i(x)]$, denote the generators of A_i, $i=1, 2$.

$$[L^1(x)]^T = [T^{-1}L^1(x)T] = [L^2(xT)],$$

so $[L^1(x)]^T = [L^2(x)]$ for x and hence xT range over all of V.

For arbitrary a_i in $\mathfrak{L}$,

$$(\sum a_i)^T = \sum a_i^T, \qquad (-a_i)^T = -a_i^T, \qquad (a_i a_j)^T = a_i^T a_j^T$$

so A_1 is mapped isomorphically onto A_2 by the given inner automorphism of $\mathfrak{L}$.

Example. The converse of Theorem 3 is not valid, as shown by the following example. As before, V denotes a right vector space. Let the identity and zero linear transformations of V be denoted by I and 0 respectively.

Let $L^1(x) = I$ for each x in V. A check of conditions (a) and (b) show that L^1 defines a near-ring N_1. Now select an x in V and let $L^2(x) = I$, $L^2(y) = 0$ for $x \neq y$. L^2 defines a near-ring N_2 and clearly N_1 is not isomorphic to N_2. However, the associated rings A_1 and A_2 are identical.

The encouragement given by Dr. J. L. Zemmer in preparing this note has been most helpful.

ENUMERATION OF CANONICAL SETS BY RANK

J. V. BRAWLEY, JR., Clemson University

1. Introduction. Let M be the set of square $n \times n$ matrices over the finite field $GF(q)$. By a canonical set for M we shall mean a subset C of M with the property that each $A \in M$ is similar to one and only one matrix in C. It is clear that every canonical set for M has the same number $N(n, q)$ of elements. This number has

ON A CONJECTURE OF ERDÖS, HAJNAL AND MOON

B. BOLLOBÁS, L. Eötvös University, Budapest

In the following we shall prove a conjecture of Erdös, Hajnal and Moon, published in [1]. For the sake of completeness, we repeat some of the definitions of that article.

A *graph* consists of a finite set of vertices, some pairs of which are joined by an edge. We do not permit loops or multiple edges. An n by m bipartite graph has n "green" and m "blue" vertices with all its edges joining vertices of different color. We call a k by l bipartite graph complete if all green and blue vertices are connected. We say that an n by m (bipartite) graph has property (k, l) if any new edge increases the number of complete k by l bipartite graphs in this graph (naturally we assume $k \leqq n$, $l \leqq m$). Erdös, Hajnal and Moon conjectured that every n by m bipartite graph with property (k, l) has at least $(k-1)m+(l-1)n-(k-1)(l-1)$ edges, and now we verify this conjecture.

THEOREM. *Every n by m bipartite graph with property (k, l) has at least $(k-1)m+(l-1)n-(k-1)(l-1)$ edges.*

Note that this is the same as saying that the graph cannot lack more than $(n-k+1)(m-l+1)$ edges. We use induction on k and l. For $k=l=1$ the statement is trivial. Because of the symmetry of k and l it is sufficient to prove that if it holds for property (k, l) it also holds for $(k+1, l)$.

Let G be an n by m graph with property $(k+1, l)$ and let $\overline{G}$ be its complement (i.e., $\overline{G}$ has the same vertices as G and two vertices of different color are joined in $\overline{G}$ if and only if they are not joined in G). Let α_i $(i=1, 2, \cdots, \mu)$ be the edges of $\overline{G}$. Our aim is to prove that $\mu \leqq (n-k)(m-l+1)$. Since G is a graph with property $(k+1, l)$, in $\overline{G}$ we can certainly choose, for each edge α_i some set G_i of $k+1$ blue and l green vertices such that α_i is the only edge in G_i. Let the blue vertices of G_i be $x_0^i, x_1^i, \cdots, x_k^i$, where α_i is incident with the vertex x_0^i. We say that α_i (or G_i) *assigns a weight* $n-k$ to x_0^i and a weight 1 to x_j^i $(j=1, 2, \cdots, k)$ for every $i=1, 2, \cdots, \mu$.

(a) We shall show that the α_i's altogether assign a weight of at most $(n-k)(m-l+1)$ to an arbitrary blue vertex a.

Suppose that r edges are joined to a in $\overline{G}$. Now $r \leqq m-l+1$, for a obviously must be joined to at least $l-1$ green vertices in G. These edges assign a weight of $r(n-k)$ to a.

The other edges of $\overline{G}$ assigning weight to a cannot be joined to these r edges for otherwise there would be at least two edges in some G_i; so they must be in an $(n-1, m-r)$ bipartite subgraph of $\overline{G}$, say G^*. Moreover if an edge α_i of G^* assigns a weight (and consequently weight 1) to a, every vertex, except a of G_i must be in G^*. Hence for each edge α_i of G^* there is a (k, l) bipartite graph of G^*, the only edge of which is α_i. Hence by the induction hypothesis the number of edges α_i of G^* is at most $(n-k)(m-r-l+1)$.

Consequently the weight assigned to a is at most $r(n-k)+(n-k)(m-r-l+1)$ $=(n-k)(m-l+1)$.

(b) Now each α_i $(i=1, 2, \cdots, \mu)$ assigns a weight n to the set of blue vertices. Thus by (a):

$$n\mu \leqq n(n-k)(m-l+1).$$

So $\mu \leqq (n-k)(m-l+1)$, and this proves the theorem.

It is easily seen that this result is best possible. One of the many extremal graphs is the following.

Let $x_1, x_2, \cdots, x_n$ be the blue and $y_1, y_2, \cdots, y_m$ the green vertices. Connect the vertices $x_1, x_2, \cdots, x_{k-1}$ with every green vertex and the other blue vertices with $y_1, y_2, \cdots, y_{l-1}$. It is almost obvious that this n by m graph has property (k, l), and it has $(k-1)m+(l-1)n-(k-1)(l-1)$ edges. We do not make an attempt to enumerate all the extremal graphs.

We may restate the theorem in a slightly weaker form: If an n by m bipartite graph does not contain a complete (k, l) graph but upon adding any new edge it loses this property, then the graph has at least $(k-1)m+(l-1)n-(k-1)(l-1)$ edges. This statement can be considered as the dual of a problem of Zarankiewicz (cf. [2]), who proposed the problem of determining the graphs with this property which have the maximal number of edges.

SOME CONGRUENCES FOR k LINE PARTITIONS OF A NUMBER

J. M. GANDHI, University of Alberta, Edmonton

In this note we derive the following interesting congruences for $t_k(n)$, the k line partitions of a number n:

$$t_2(2n) + t_2(2n+1) \equiv 0 \pmod 2, \tag{1}$$

$$t_3(3n+4) \equiv t_3(3n+3) \pmod 3 \tag{2}$$

$$t_4(4n) \equiv t_4(4n+2) \equiv t_4(4n+1) \pmod 2 \tag{3}$$

$$t_4(4n+3) \equiv 0 \pmod 2 \tag{4}$$

$$t_5(5n+1) \equiv t_5(5n+3) \pmod 5 \tag{5}$$

$$t_5(5n+2) \equiv t_5(5n+4) \pmod 5, \tag{6}$$

where $t_k(n)$ is defined as

$$\prod_m (1-x^m)^{-\min(m,k)} = \sum_{n=0}^{\infty} t_k(n)x^n. \tag{7}$$

Define $p_\gamma(n)$ as

$$\left[\prod_m (1 - x^m)\right]^\gamma = \sum_{n=0}^{\infty} p_\gamma(n)x^n. \tag{8}$$

Then from the identities

$$t_2(n) = p_{-2}(n) - p_{-2}(n-1) \tag{9}$$

and

$$t_3(n) = p_{-3}(n) - 2p_{-3}(n-1) + 2p_{-3}(n-3) - p_{-3}(n-4). \tag{10}$$

Cheema and Gordon [1] proved that

$$t_2(n) \equiv 0 \pmod 5 \quad \text{if } n \equiv 3 \text{ or } 4 \pmod 5 \tag{11}$$

and

$$t_3(n) \equiv 0 \pmod 3 \quad \text{if} \quad n \equiv 2 \pmod 3. \tag{12}$$

Using the following two theorems of Gandhi [2] namely

THEOREM 1. *If* $(k/n) = (m/t) = (m, t) = 1$ *then* $p_{\alpha k}(n) \equiv 0 \pmod m$ *for* $\alpha = \pm 1$.

THEOREM 2. *If* R *is a prime, then* $p_{kR}(mR) \equiv p_k(m) \pmod R$ *the congruences* (11) *and* (12) *immediately follow from the identities* (9) *and* (10).

Now replacing n by $2n$ and $2n+1$ respectively in (9) we get

$$t_2(2n) = p_{-2}(2n) - p_{-2}(2n-1), \tag{13}$$

$$t_2(2n+1) = p_{-2}(2n+1) - p_{-2}(2n). \tag{14}$$

Adding (13) and (14) we get (1).

In view of Theorems 1 and 2, we have

$$p_{-2}(2n) \equiv p_{-1}(n) \pmod 2 \quad \text{and} \quad p_{-2}(2n+1) \equiv 0 \pmod 2. \tag{15}$$

Using (15), from (13) and (14) we get

$$t_{2n} \equiv p_{-1}(n) \pmod 2 \tag{16}$$

$$t_2(2n+1) \equiv p_{-1}(n) \pmod 2. \tag{17}$$

From which we conclude that for a particular value of n, $t_2(2n)$, $t_2(2n+1)$ and $p_{-1}(n)$ have the same parity. It is to be noted that with the definition of $p_\gamma(n)$ as given by (8), $p_{-1}(n)$ denotes the unrestricted partitions of a number.

Now in identity (10), replace n by $3n+1$ and $3n+3$ respectively to get

$$t_3(3n+1) = p_{-3}(3n+1) - 2p_{-3}(3n) + 2p_3(3n-2) - p_{-3}(3n-3), \tag{18}$$

$$t_3(3n+3) = p_{-3}(3n+3) - 2p_{-3}(3n+2) + 2p_{-3}(3n) - p_{-3}(3n-1). \tag{19}$$

In view of Theorems 1 and 2, we have $p_{-3}(3n+1)$, $p_{-3}(3n-2)$,

$$p_{-3}(3n+2), \qquad p_{-3}(3n-1) \text{ each} \equiv 0 \pmod 3$$

and

$$\begin{aligned} p_{-3}(3n) &\equiv p_{-1}(n), \qquad p_{-3}(3n+3) \equiv p_{-1}(n+1) \\ p_{-3}(3n-3) &\equiv p_{-1}(n-1) \pmod 3. \end{aligned} \tag{20}$$

Using (20) from (18) and (19) we get

$$t_3(3n+1) \equiv p_{-1}(n) - p_{-1}(n-1) \bmod 3), \tag{21}$$

$$t_3(3n+3) \equiv p_{-1}(n+1) - p_{-1}(n) \pmod 3. \tag{22}$$

Replacing n by $n+1$ in (21) and subtracting it from (22), we get congruence (2).

Congruences (4)–(6) can be proved exactly on the same lines as that of congruence (2) and follow from the same technique and observing that

$$\begin{aligned} \sum_{n=0}^{\infty} t_4(n)x^n &= \left\{ \sum_{n=0}^{\infty} p_{-4}(n)x^n \right\} (1-x)^3(1-x^2)^2(1-x^3) \\ &= \sum_{n=0}^{\infty} p_{-4}(n)x^n \left\{ \sum_{i=0}^{10} a_i x^i \right\} \end{aligned}$$

which implies that $t_4(n) = \sum_{i=0}^{10} a_i p_{-4}(n-i)$ and a similar expression for $t_5(n)$, namely

$$t_5(n) = \sum_{i=0}^{20} b_i p_{-5}(n-i).$$

For future reference we give below the values of the coefficients a_i and b_i.

$$\begin{aligned} &a_0 = +1, \quad a_1 = -3, \quad a_2 = +1, \quad a_3 = +4, \quad a_4 = -2, \quad a_5 = -2, \\ &b_0 = +1, \quad b_1 = -4, \quad b_2 = +3, \quad b_3 = +6, \quad b_4 = -7, \quad b_5 = -2, \\ &b_6 = -4, \quad b_7 = +10, \quad b_8 = +6, \quad b_9 = -10, \quad b_{10} = +2. \end{aligned}$$

The remaining a_i's and b_i's can be calculated from the formulae $a_{10-i} = a_i$ and $b_{20-i} = b_i$.

Added in Proof: We have obtained a large number of congruences for $t_k(n)$, where $k = 6, 7, 8$ and 9, which will be published soon.

Acknowledgments. The author is grateful to Prof. L. Carlitz and Prof. H. Gupta for their kind encouragement and to Prof. M. F. Soonawala for helpful discussions.

The author is on leave from University of Rajasthan, Jaipur (India).

A GENERATING FUNCTION FOR THE GENERALIZED BESSEL POLYNOMIALS

MRINAL KANTI DAS, c/o Bangabasi College, Calcutta, India

1. In [1] Burchnall remarked that his operational methods enabled him to repair one omission in [2], namely the failure to supply a generating function for the generalized Bessel polynomials $y_n(x; a, b)$. The generating function for the polynomials $y_n(x; a, b)$ supplied by Burchnall is

$$[\tfrac{1}{2} + \tfrac{1}{2}(1 - 2xt)^{1/2}]^{2-a}(1 - 2xt)^{-1/2} \exp\left[\frac{b}{2x}\{1 - (1 - 2xt)^{1/2}\}\right] = \sum_{n=0}^{\infty} \frac{(b/2)^n y_n(x; a, b)}{n!} t^n. \tag{1.1}$$

The object of this note is to present a very simple proof of (1.1) based on Lagrange's theorem.

2. The generalized Bessel polynomials $y_n(x; a, b)$ can be defined by

$$y_n(x; a, b) = b^{-n}x^{2-a}e^{b/x}D^n(x^{2n+a-2}e^{-b/x}). \tag{2.1}$$

Now Lagrange's theorem states that if $u = x + t\phi(u)$ where, when u is many-valued, that branch is taken which converges to x when $t \to 0$, then

$$f(u) = f(x) + \sum_{n=1}^{\infty} \frac{t^n}{n!} \frac{d^{n-1}}{dx^{n-1}}\left[\{\phi(x)\}^n \frac{d}{dx} f(x)\right]. \tag{2.2}$$

From (2.2) we easily deduce that

$$\frac{\partial}{\partial x} f(u) = \sum_{n=0}^{\infty} \frac{t^n}{n!} D^n[\{\phi(n)\}^n \cdot f'(x)]. \tag{2.3}$$

We remark that (2.3) may be conveniently applied to find the generating functions of those orthogonal polynomials whose Rodrigues' formulae are such that Taylor's formula, viz., $e^{tD}f(x) = f(x+t)$, fails to supply the desired generating functions.

Now let us rediscover the generating function (1.1) by use of Lagrange's theorem. For this purpose we take $\phi(x) = x^2$

$$f'(x) = x^{a-2}e^{-b/x} \quad \text{and} \quad u = x + (t/2)u^2$$

so that

$$u = \frac{1}{t}(1 - \sqrt{(1 - 2xt)}),$$

since we are to have $u = x$, when $t \to 0$. Thus it at once follows from (2.3) that

$$f'(u)\frac{\partial u}{\partial x} = \sum \frac{(t/2)^n}{n!} D^n(x^{2n} \cdot x^{a-2}e^{-b/x}). \tag{2.4}$$

Now we obtain from (2.1) and (2.4)

$$u^{a-2}e^{-b/u}(1-2xt)^{-1/2} = x^{a-2}e^{-b/x}\sum_{n=0}^{\infty}\frac{(b/2)^n y_n(x;\,a,\,b)}{n!}\,t^n$$

whence we derive

$$[1-\tfrac{1}{2}(1-\sqrt{(1-2xt)})]^{2-a}(1-2xt)^{-1/2}\exp[(b/2x)(1-\sqrt{(1-2xt)})] = \sum_{n=0}^{\infty}\frac{(b/2)^n y_n(x;\,a,\,b)}{n!}\,t^n.$$

I thank Dr. S. K. Chatterjea for his kind help in the preparation of this note.

COMMUTING MAPS LACKING COMMUTING EXTENSIONS

D. R. Anderson and D. C. Kay, University of Wyoming

The following problem was recently proposed by De Marr [1]: Let X be a topological space which has the property that every continuous function (map) from a closed subset X_0 of X to itself may be extended to a map of X. Further, let f and g be two commuting maps of X_0 into X_0, that is, $f(g(x))=g(f(x))$ for all $x\in X_0$. Then, do there exist continuous extensions of f and g to the whole space X which commute? The answer to this is in the negative even for the case $X=[0,\,1]$, as we shall show.

Let $X=[0,\,1]$ and suppose that X_0 denotes a closed subset of X, with f and g commuting maps of X_0 into X_0. In the cases (a) $g=f$, (b) $g=i$ (identity), (c) $g=f=i$ on the boundary of X_0, and (d) $g=C$ (constant), and $f(C)=C$, it is easy to provide extensions to X which commute. In (c) one may take $F=G=i$ on $X-X_0$ and $F=f$, $G=g$ on X_0. The continuity and commutativity of F and G readily follow. Consider, however, the example:

$$\left.\begin{aligned} f(x) &= g(x) = 1 \\ f(x) &= x/2 - 1/3 \\ g(x) &= -x/2 + 2/3 \end{aligned}\right\} \quad \begin{aligned} &\text{for } 0 \leqq x \leqq 1/3, \\ &\text{for } 2/3 \leqq x \leqq 1. \end{aligned}$$

Here, $X_0=[0,\,\frac{1}{3}]\cup[\frac{2}{3},\,1]$.

Let F, G be continuous extensions of f and g, respectively, and suppose that $x_0=\inf\{x\colon F(x)=\frac{2}{3}\}$ and $x_1=\inf\{x\colon G(x)=\frac{2}{3}\}$. Since F and G are continuous, $F(x_0)=G(x_1)=\frac{2}{3}$ and, if $x_0\leqq x_1$ then $G(x_0)\geqq\frac{2}{3}$, with equality only when $x_0=x_1$. Hence

$$G(F(x_0)) = G(2/3) = 1/3,$$

while

$$F(G(x_0)) \leqq 1/6.$$

Thus $G(F(x_0)) \neq F(G(x_0))$. Similarly, if $x_1 < x_0$ then we may prove that $F(G(x_1)) = 0$ and $G(F(x_1)) \geqq \frac{1}{6}$. Therefore no continuous extensions of f and g have the commuting property, even though f and g themselves commute.

We observe that in the above example X_0 was not connected. This is necessary, for otherwise X_0 would be a closed interval and in that event one may always extend commuting maps f and g over X_0 to commuting maps over X. Perhaps the connectivity of X_0 is of some importance to the general problem. Another feature which may be significant in more general spaces is the monotonicity of the functions f and g. In our example, g was monotonic (decreasing) while f was not monotonic.

FORBIDDEN REGIONS ARE CONVEX

DAVID SINGMASTER AND GERALDA SINGMASTER, American University of Beirut

Ogilvy [1] has raised the following problem: Consider a triangle T of area A. Let S_k be the set of points such that if $p \in S_k$, then there is no line through p which cuts the triangle into pieces of area kA and $(1-k)A$. Is S_k simply connected?

Hoggatt [2] has presented a solution to this problem through use of oblique coordinates. He describes S_k as a "forbidden region" and attributes the problem to Free Jamison [3].

In this note, we shall present an elementary proof that the analogous sets S_k are convex for any region T of finite n-measure in n-space ($n \geqq 2$), using only ideas of continuity.

We may assume, without loss of generality, that T has measure 1. We shall call a hyperplane in n-space simply a plane. We let $V(S)$ be the n-dimensional Lebesgue measure of S which we will call the volume or measure of S.

DEFINITIONS. *A k-plane P is a plane which divides T into two regions having measure k and $1-k$, where we take $0 \leqq k \leqq \frac{1}{2}$.*

A k-point p is a point on some k-plane.

$$S_k = \{p \mid p \text{ is not a } k\text{-point}\}.$$

The following Lemma is an n-dimensional analog of the well-known fact that if T is a set of finite measure in the reals, then the function $f(x) = V(T \cap (-\infty, x))$ is continuous in x.

LEMMA. *If a plane P rotates about an axis A in P (i.e., A is an $(n-2)$-dimensional subset of P), then the measures $V_1(\theta)$, $V_2(\theta)$, of the subsets T_1, T_2 of T which lie on each side of P, vary continuously with θ.*

Proof. Take any $\epsilon>0$. From the definition of Lebesgue measure in n-space, there is a bounded set B such that $V(B\cap T)>1-\epsilon/2$. Let $d(x, y)$ be Euclidean distance. Let $R=\sup\{d(A, t)\,|\,t\in B\cap T\}$ and let $D=\operatorname{diam}(B\cap T)=\sup\{d(s, t)\,|\,s, t\in B\cap T\}$. Then if P rotates through an angle δ, it sweeps through a region of $B\cap T$ which is contained in two sections of an n-dimensional right circular "cylinder" whose axis is A, whose $(n-2)$-dimensional "height" is D^{n-2}, whose radius is R and whose angle is $|\delta|$. Hence the changes in volume of $B\cap T_1$ and $B\cap T_2$ are at most $2(\frac{1}{2}R^2|\delta|)D^{n-2}=R^2D^{n-2}|\delta|$. Consequently, if we take $|\delta|<\epsilon/2R^2D^{n-2}$, then these changes are less than $\epsilon/2$. Adding in the changes which occur in $T\sim B$, which are also less than $\epsilon/2$, we see that $V_1(\theta)$ and $V_2(\theta)$ change by no more than ϵ.

THEOREM 1. *Let p be a k-point. Then p is a j-point for all j, $k\leqq j\leqq\frac{1}{2}$.*

Proof. Let P be a k-plane through p and let A be any axis in P, through p. As P rotates from its original position through an angle θ, let $V_1(\theta)$ and $V_2(\theta)$ be the volumes of the regions T_1 and T_2 lying on each side of P. We may assume that $V_1(0)\leqq V_2(0)$, so that $V_1(0)=k$ and $V_2(0)=1-k$. But when $\theta=\pi$, the regions T_1 and T_2 have been interchanged, so that $V_1(\pi)=1-k$. Since $V_1(\theta)$ is continuous, it takes on every value j such that $k\leqq j\leqq\frac{1}{2}(\leqq 1-k)$.

COROLLARY. $0\leqq k\leqq j\leqq\frac{1}{2}$ *implies* $S_j\subset S_k$.

COROLLARY. *Every point is a $\frac{1}{2}$-point, i.e.,* $S_{1/2}=\phi$.

COROLLARY. $S_k\subset S_0\subset T'$, *where T' is the convex closure of T.*

The last corollary depends on the observation that if $p\notin T'$, then there is a plane through p which does not meet T' and hence, is a 0-plane. It is easy to see that $S_0\neq T'$ can hold. It is clear that S_0 is the interior of T when T is convex, but $S_0\neq\operatorname{int}(T')$ can hold.

THEOREM 2. S_k *is convex for all* k, $0\leqq k\leqq\frac{1}{2}$.

Proof. Let p, q be in $S_k(p\neq q)$, and suppose that r is a point on the line segment pq and $r\notin S_k$. Then r is a k-point and there is a k-plane P through r. Neither p nor q can be on P so the line pq meets P in the unique point r. Therefore p and q lie on opposite sides of P. From the symmetry of the situation, we may suppose that p lies on the same side of P as does the region T_1 of smaller volume $V_1=k$, of the two regions into which P divides T. Consider the plane P' through p and parallel to P. Let T_1' be the region of T_1 which lies on the *outside* of P' (i.e. on the other side from P). Clearly the volume V_1' of T_1' is less than $V_1=k$, since $T_1'\subset T_1$. Let $V_1'=j$; then p is a j-point and $j\leqq k$. Consequently, p is a k-point by Theorem 2, contrary to hypothesis. Hence r cannot be a k-point and S_k must be convex.

COROLLARY. *S_k is simply connected.*

Note that the restriction throughout that $0 \leqq k \leqq \frac{1}{2}$ does not involve any loss of generality since $S_k = S_{1-k}$.

A natural problem suggested by this work is to find $k_0 = \inf\{k \mid S_k = \phi\}$. Hoggatt's work shows that $k_0 = 4/9$ for a triangle in 2-space.

The first author was an NSF Graduate Fellow at the University of California at the time of writing this paper.

ABSTRACT ALGEBRAS WITH A SINGLE OPERATION AND GROUP-LIKE AXIOMS

D. J. ALLEN, Bennington, Vermont

Abstract algebras and abstract operations are defined in [1]. It is revealing to study the structure of an abstract algebra by focussing attention on a single operation and axioms generalized from group theory. It is assumed throughout that the operations are of finite rank $n > 2$. The structures resulting from the imposition of these axioms are called suggestively hypersemigroups and hypergroups. The main result of this paper is to show that these axioms are necessary and sufficient conditions for n-products in hypersemigroups with identity and hypergroups to be rewritten as iterated binary products derived from the abstract operation. In other words, with either of these two structures, it is always possible to find a plane section of its "Cayley multiplication table" which determines the entire table.

AXIOM I. Associativity:

$$\begin{aligned}(a_1a_2 \cdots a_{n-1}(a_n \cdots a_{2n-1})) &= (a_1a_2 \cdots a_{n-2}(a_{n-1} \cdots a_{2n-2})a_{2n-1}) \\ &= \cdots = ((a_1a_2 \cdots a_n)a_{n+1} \cdots a_{2n-1}).\end{aligned}$$

AXIOM II. Identity: There exists a unique $e \in A$ such that

$$(ae \cdots e) = (eae \cdots e) = \cdots = (e \cdots ea) = a$$

for all $a \in A$.

AXIOM III. Inverse: For each $a \in A$, there exists a unique $(n-1)$-tuple $b_1b_2 \cdots b_{n-1}$, $(b_i \in A)$ such that $(ab_1b_2 \cdots b_{n-1}) = (b_1b_2 \cdots b_{n-1}a) = e$.

DEFINITION I. *A hypersemigroup with identity S_n^1 is a pair composed of a nonempty set S_n^1 and an n-ary operation which satisfies Axioms I and II.*

DEFINITION II. *A hypergroup G_n is a hypersemigroup with identity which also satisfies Axiom III.*

It follows immediately from Axioms I and II that in any hypersemigroup with identity S_n^1 the identity commutes with all elements of S_n^1 in the sense that

$$(ea_1a_2 \cdots a_{n-1}) = (a_1ea_2 \cdots a_{n-1}) = \cdots$$
$$= (a_1a_2 \cdots a_{m-1}ea_m \cdots a_{n-1}) = \cdots = (a_1a_2 \cdots a_{n-1}e).$$

We have, in fact:

LEMMA I. *In any hypersemigroup with identity S_n^1, the value of an n-product $(a_1 \cdots a_n)$ remains unchanged under all permutations which leave the order of the elements $a_i \neq e$ unchanged.*

THEOREM I. *If S_n^1 is an abstract algebra with one operation and if there exists a semigroup with identity S^1 defined on the same set as S_n^1 and whose binary operation is derived from the operation in S_n^1 and such that each n-product in S_n^1 can be rewritten as an iteration of the binary operation in S^1, then it is necessary and sufficient that S_n^1 be a hypersemigroup with identity.*

Proof. It is obvious that the identity in S^1 is also an identity in S_n^1. Likewise, the operation in S_n^1 is associative since S^1 is a semigroup. On the other hand, we can define a binary operation by the relation $(abe \cdots e) = a * b$. The operation $(*)$ is associative since $(a(bce \cdots e)e \cdots e) = ((abe \cdots e)ce \cdots e) \Rightarrow a * (b * c) = (a * b) * c$. We also have $e * a = a * e = a$. Thus the pair $(S_n^1, *)$ is a semigroup with identity S^1. Let $(a_1a_2 \cdots a_n)$ be any n-product in S_n^1. Now $a_1 * a_2 = (a_1a_2e \cdots e)$ and $a_1 * a_2 * a_3 = (a_1a_2a_3e \cdots e)$ as is easily verified. If this process is continued, the product $a_1 * a_2 * \cdots * a_n = (a_1a_2 \cdots a_n)$ can be constructed, which completes the proof.

We now turn to an arbitrary hypergroup G_n.

LEMMA II. *For each of the equations*

$$(xa_1 \cdots a_{n-1}) = b_1$$
$$\cdots\cdots\cdots\cdots\cdots$$
$$(a_1 \cdots a_mxa_{m+1} \cdots a_{n-1}) = b_{m+1}$$
$$\cdots\cdots\cdots\cdots\cdots$$
$$(a_1 \cdots a_{n-1}x) = b_n$$

there exists a unique solution in G_n.

Proof. Let A_{n-1}^{-1} represent the $(n-1)$-tuple inverse to a_{n-1}. Then

$$((xa_1 \cdots a_{n-1})A_{n-1}^{-1}) = (xa_1 \cdots a_{n-2}(a_{n-1}A_{n-1}^{-1})) = (xa_1 \cdots a_{n-2}e)$$
$$= (xea_1 \cdots a_{n-2}) = b_1A_{n-1}^{-1}.$$

Repeating this process leads to $x = b_1A_{n-1}^{-1} \cdots A_1^{-1} = c$. Since the A_i^{-1} are each unique, the solution is unique. The other cases are proven in a similar manner.

COROLLARY. *For every* $(n-1)$*-tuple* $a_1 \cdot \cdot \cdot a_{n-1}$ *in* G_n *there exists a unique* $b \in G_n$ *such that* $(ba_1 \cdot \cdot \cdot a_{n-1}) = e$.

THEOREM II. *If* G_n *is an abstract algebra with one operation and if there exists a group* G *defined on the same set as* G_n *and whose binary operation is derived from the operation in* G_n *and such that each n-product in* G_n *can be rewritten as an iteration of the binary operation in* G, *then it is necessary and sufficient that* G_n *be a hypergroup.*

Proof. We know from Theorem I that G_n is a hypersemigroup with identity. For any $a \in G_n$ there exists a unique $(n-1)$-tuple $a^{-1}e \cdot \cdot \cdot e$ such that $(a^{-1}e \cdot \cdot \cdot ea) = (aa^{-1}e \cdot \cdot \cdot e) = e$, since G is a group. On the other hand, we define a binary operation $(*)$ in the same way as in Theorem I. This results in a semigroup with identity G. We see from the corollary to Lemma II that if $ae \cdot \cdot \cdot e$ is an $(n-1)$-tuple in G_n, there exists a unique a^{-1} such that $(a^{-1}ae \cdot \cdot \cdot e) = a^{-1} * a = e$, so that the pair $(G_n, *)$ is a group. The rest of the proof follows as in Theorem I.

I wish to thank the referee for a very valuable suggestion.

CLASSROOM NOTES

THE SCARCITY OF CROSS PRODUCTS ON EUCLIDEAN SPACES

BERTRAM WALSH, University of California, Los Angeles

When first introduced to the dot product on $\mathbf{R}^n$ (n arbitrary) and the cross product on $\mathbf{R}^3$, students are not unlikely to inquire about the definition of a cross product for $\mathbf{R}^n$, $n \neq 3$. This note points out that by proving the elementary propositions and theorem below, students may answer this question themselves. Namely, they may show that if reasonable demands are made of "cross products" (that they satisfy the axioms for cross products in Apostol's recent Calculus text [2]), then only on $\mathbf{R}^1$, $\mathbf{R}^3$ and $\mathbf{R}^7$ can cross products exist—the one on $\mathbf{R}^1$ being trivial and the ones on $\mathbf{R}^7$ somewhat pathological. We indicate the elementary proofs, for whose rediscovery students will need knowledge of the fact that orthonormal (o.n.) sets in $\mathbf{R}^n$ have cardinalities $\leqq n$, with equality if and only if the o.n. set is a basis; orthogonal projection is required a couple of times, but projection is onto a subspace for which an orthonormal basis has already been constructed, so that the projection can be written out explicitly, componentwise.

The axioms [2, p. 275] are

(5.28) $\mathbf{a} \times \mathbf{b} = -(\mathbf{b} \times \mathbf{a})$

(5.29) $\mathbf{a} \times (\mathbf{b} + \mathbf{c}) = (\mathbf{a} \times \mathbf{b}) + (\mathbf{a} \times \mathbf{c})$

(5.30) $\lambda(\mathbf{a} \times \mathbf{b}) = (\lambda\mathbf{a}) \times \mathbf{b}$

(5.31) $\mathbf{a} \cdot (\mathbf{a} \times \mathbf{b}) = 0$

(5.32) $|\mathbf{a} \times \mathbf{b}| = [|\mathbf{a}|^2 |\mathbf{b}|^2 - (\mathbf{a} \cdot \mathbf{b})^2]^{1/2}$

for all scalars λ and all vectors $\mathbf{a}, \mathbf{b}, \mathbf{c}$. One can easily verify that in the presence of the other four axioms, (5.32) is equivalent to the statement that the cross product of two orthogonal unit vectors is also a unit vector, so that in spite of its complicated appearance the axiom is natural.

Our principal tools are the identities

(1) $$(\mathbf{a} \times \mathbf{b}) \cdot \mathbf{c} = -[\mathbf{b} \cdot (\mathbf{a} \times \mathbf{c})]$$

and

(2) $$\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) - \mathbf{c} \times (\mathbf{a} \times \mathbf{b}) = 2(\mathbf{a} \cdot \mathbf{c})\mathbf{b} - (\mathbf{b} \cdot \mathbf{c})\mathbf{a} - (\mathbf{a} \cdot \mathbf{b})\mathbf{c};$$

the first of these, which expresses the fact that the linear transformation $\mathbf{b} \to (\mathbf{a} \times \mathbf{b})$ is skew-symmetric, is easily derived from (5.31) by setting $\mathbf{a}+\mathbf{c}$ where $\mathbf{a}$ occurs, using linearity and symmetry, and canceling what one already knows about. The second is derived by two applications of the "polarization" trick: writing (5.32) as

$$(\mathbf{a} \times \mathbf{b}) \cdot (\mathbf{a} \times \mathbf{b}) = (\mathbf{a} \cdot \mathbf{a})(\mathbf{b} \cdot \mathbf{b}) - (\mathbf{a} \cdot \mathbf{b})^2$$

and setting $\mathbf{b}+\mathbf{d}$ where $\mathbf{b}$ is, using bilinearity and symmetry to get an expansion of both sides and canceling what one already knows about, one gets

$$(\mathbf{a} \times \mathbf{b}) \cdot (\mathbf{a} \times \mathbf{d}) = (\mathbf{a} \cdot \mathbf{a})(\mathbf{b} \cdot \mathbf{d}) - (\mathbf{a} \cdot \mathbf{b})(\mathbf{a} \cdot \mathbf{d}).$$

This can be written, using (1) and the linearity of the dot product, as

$$-[\mathbf{a} \times (\mathbf{a} \times \mathbf{b})] \cdot \mathbf{d} = [(\mathbf{a} \cdot \mathbf{a})\mathbf{b} - (\mathbf{a} \cdot \mathbf{b})\mathbf{a}] \cdot \mathbf{d}$$

and since $\mathbf{d} \in \mathbf{R}^n$ is arbitrary, this gives

(3) $$\mathbf{a} \times (\mathbf{a} \times \mathbf{b}) = (\mathbf{a} \cdot \mathbf{b})\mathbf{a} - (\mathbf{a} \cdot \mathbf{a})\mathbf{b},$$

a useful special case of (2). Now setting $\mathbf{a}+\mathbf{c}$ wherever $\mathbf{a}$ is in (3), expanding by linearity, canceling what one already knows about and using the skew-symmetry of the cross product (i.e. (5.28)) leads directly to (2). A useful special case, incidentally, is

(4) For mutually orthogonal $\mathbf{a}, \mathbf{b}, \mathbf{c}$, $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = \mathbf{c} \times (\mathbf{a} \times \mathbf{b})$

which one sees by observing that the right side of (2) is zero whenever $\mathbf{a}, \mathbf{b}$ and $\mathbf{c}$ are mutually orthogonal. The identities (1), (2), (3) and (4) hold for any cross product satisfying the axioms, on any $\mathbf{R}^n$.

Given such a cross product on $\mathbf{R}^n$, we make two definitions:

(I) A vector subspace A of $\mathbf{R}^n$ is *closed under* $\times$ if whenever $\mathbf{a}_1 \in A$ and $\mathbf{a}_2 \in A$, then also $\mathbf{a}_1 \times \mathbf{a}_2 \in A$.

(II) A subspace B of $\mathbf{R}^n$ is *stable under* $A\times$, where $A \subseteq \mathbf{R}^n$, if whenever $\mathbf{a} \in A$ and $\mathbf{b} \in B$, then $\mathbf{a} \times \mathbf{b} \in B$.

So A is closed under $\times$ iff stable under $A\times$. We now have

PROPOSITION 1. *Let $A \subseteq \mathbf{R}^n$, B be a subspace of $\mathbf{R}^n$. If B is stable under $A\times$, then so is its orthogonal complement $B^\perp = \{\mathbf{c} \mid \mathbf{c} \in \mathbf{R}^n, \mathbf{b}\cdot\mathbf{c} = 0$ for all $\mathbf{b} \in B\}$.*

Proof. If $\mathbf{c} \in B^\perp$, then for any $\mathbf{a} \in A$ and $\mathbf{b} \in B$

$$\mathbf{b}\cdot(\mathbf{a} \times \mathbf{c}) = -[(\mathbf{a} \times \mathbf{b})\cdot\mathbf{c}] = 0 \quad \text{since } \mathbf{a} \times \mathbf{b} \in B.$$

Thus for any $\mathbf{b} \in B$, $\mathbf{b} \perp (\mathbf{a}\times\mathbf{c})$, and so $\mathbf{a}\times\mathbf{c} \in B^\perp$. ∎

PROPOSITION 2. *Let A be a subspace of $\mathbf{R}^n$ which is closed under $\times$ and possesses an orthonormal basis $\{\mathbf{f}_1, \cdots, \mathbf{f}_k\}$. Let $\mathbf{b} \in A^\perp$. Then the vectors $\{\mathbf{b}, \mathbf{f}_1\times\mathbf{b}, \cdots, \mathbf{f}_k\times\mathbf{b}\}$ lie in $A^\perp$ and are mutually orthogonal and of the same length as $\mathbf{b}$. In particular if $\mathbf{b}$ is a unit vector they form an orthonormal set of $k+1$ elements in $A^\perp$.*

Proof. That $\{\mathbf{b}, \mathbf{f}_1\times\mathbf{b}, \cdots\} \subseteq A^\perp$ follows from Proposition 1. The orthogonality relations and lengths follow from $\mathbf{b}\cdot(\mathbf{f}_i\times\mathbf{b}) = 0$ and

$$\begin{aligned}(\mathbf{f}_i \times \mathbf{b})\cdot(\mathbf{f}_j \times \mathbf{b}) &= (\mathbf{b} \times \mathbf{f}_i)\cdot(\mathbf{b} \times \mathbf{f}_j)\\ &= -[\mathbf{b} \times (\mathbf{b} \times \mathbf{f}_i)\cdot\mathbf{f}_j] \quad \text{by (1)}\\ &= -[(\mathbf{b}\cdot\mathbf{f}_i)\mathbf{b} - (\mathbf{b}\cdot\mathbf{b})\mathbf{f}_i]\cdot\mathbf{f}_j = (\mathbf{f}_i\cdot\mathbf{f}_j)(\mathbf{b}\cdot\mathbf{b}).\end{aligned}$$ ∎

It is easy to verify that the only cross product on $\mathbf{R}^1$ is identically zero, and that there is no cross product on $\mathbf{R}^2$: it couldn't be zero, and there aren't enough dimensions for it to be nonzero. Suppose we have a cross product on $\mathbf{R}^n$, then, $n \geqq 3$. If $\mathbf{e}_1$ and $\mathbf{e}_2$ are an orthonormal pair of elements of $\mathbf{R}^n$, then $\mathbf{e}_1\times\mathbf{e}_2$ is a unit (by (5.32)) vector normal to both $\mathbf{e}_1$ and $\mathbf{e}_2$; set $\mathbf{e}_3 = \mathbf{e}_1\times\mathbf{e}_2$. Let H be the linear subspace of $\mathbf{R}^n$ spanned by $\{\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3\}$. Regardless of what n may be,

PROPOSITION 3. *H is closed under $\times$.*

Proof. Bilinearity of $\times$ insures that it suffices to check this on basis vectors. By identity (3)

$$\begin{aligned}\mathbf{e}_2 \times \mathbf{e}_3 = \mathbf{e}_2 \times (\mathbf{e}_1 \times \mathbf{e}_2) &= -[\mathbf{e}_2 \times (\mathbf{e}_2 \times \mathbf{e}_1)]\\ &= -[(\mathbf{e}_2\cdot\mathbf{e}_1)\mathbf{e}_2 - (\mathbf{e}_2\cdot\mathbf{e}_2)\mathbf{e}_1] = \mathbf{e}_1\end{aligned}$$

and similarly $\mathbf{e}_3\times\mathbf{e}_1 = \mathbf{e}_2$. ∎

Thus the basis $\{\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3\}$ has the same multiplication table as the basis $\{\mathbf{i}, \mathbf{j}, \mathbf{k}\}$ for $\mathbf{R}^3$ with the usual cross product.

One can resolve any vector $\mathbf{a} \in \mathbf{R}^n$ into

$$\mathbf{a} = \sum_{i=1}^{3} (\mathbf{a}\cdot\mathbf{e}_i)\mathbf{e}_i + \left[\mathbf{a} - \sum_{i=1}^{3} (\mathbf{a}\cdot\mathbf{e}_i)\mathbf{e}_i\right]$$

with the first component in H and the second in $H^\perp$. Thus either $H=\mathbf{R}^n$, in which case $n=3$, or else it is possible to find a unit vector $\mathbf{m}\in H^\perp$. Suppose the latter. Then by Proposition 2, the set $\{\mathbf{m}, \mathbf{e}_1\times\mathbf{m}, \mathbf{e}_2\times\mathbf{m}, \mathbf{e}_3\times\mathbf{m}\}$ is an orthonormal set in $H^\perp$, and $\{\mathbf{e}_1, \mathbf{e}_2, \mathbf{e}_3, \mathbf{m}, \mathbf{e}_1\times\mathbf{m}, \mathbf{e}_2\times\mathbf{m}, \mathbf{e}_3\times\mathbf{m}\}$ is an orthonormal set in $\mathbf{R}^n$, so $n\geqq 7$. Let C denote the subspace of $\mathbf{R}^n$ spanned by this last set.

PROPOSITION 4. *C is closed under $\times$.*

Proof. One need only check the five types of products which can occur:

(i) $\mathbf{e}_i \times \mathbf{e}_j$. Belongs to $H \subseteq C$, by Proposition 3.

(ii) $\mathbf{e}_i \times \mathbf{m}$. Belongs to C by definition.

(iii) $\mathbf{e}_i \times (\mathbf{e}_j \times \mathbf{m}) = 2(\mathbf{e}_i\cdot\mathbf{m})\mathbf{e}_j - (\mathbf{e}_j\cdot\mathbf{m})\mathbf{e}_i - (\mathbf{e}_i\cdot\mathbf{e}_j)\mathbf{m} + \mathbf{m}\times(\mathbf{e}_i\times\mathbf{e}_j)$
$= -(\mathbf{e}_i\times\mathbf{e}_j)\times\mathbf{m} - (\mathbf{e}_i\cdot\mathbf{e}_j)\mathbf{m} \in C.$

(iv) $\mathbf{m}\times(\mathbf{e}_i\times\mathbf{m}) = -\mathbf{m}\times(\mathbf{m}\times\mathbf{e}_i) = (\mathbf{m}\cdot\mathbf{m})\mathbf{e}_i - (\mathbf{m}\cdot\mathbf{e}_i)\mathbf{m} = \mathbf{e}_i \in C.$

(v) $(\mathbf{e}_i\times\mathbf{m})\times(\mathbf{e}_j\times\mathbf{m}) = (\mathbf{m}\times\mathbf{e}_i)\times(\mathbf{m}\times\mathbf{e}_j)$
$= \mathbf{e}_j \times [(\mathbf{m}\times\mathbf{e}_i)\times\mathbf{m}]$ by (4)
$= \mathbf{e}_j \times [\mathbf{m}\times(\mathbf{e}_i\times\mathbf{m})]$
$= \mathbf{e}_j \times \mathbf{e}_i$ by (iv) above. ∎

One can resolve any vector $\mathbf{a}\in\mathbf{R}^n$ into

$$\mathbf{a} = \left[\sum_{i=1}^{3} (\mathbf{a}\cdot\mathbf{e}_i)\mathbf{e}_i + (\mathbf{a}\cdot\mathbf{m})\mathbf{m} + \sum_{i=1}^{3} (\mathbf{a}\cdot(\mathbf{e}_i\times\mathbf{m}))(\mathbf{e}_i\times\mathbf{m})\right]$$
$$+ \left[\mathbf{a} - \sum_{i=1}^{3} (\mathbf{a}\cdot\mathbf{e}_i)\mathbf{e}_i - (\mathbf{a}\cdot\mathbf{m})\mathbf{m} - \sum_{i=1}^{3} (\mathbf{a}\cdot(\mathbf{e}_i\times\mathbf{m}))(\mathbf{e}_i\times\mathbf{m})\right]$$

with the first component in C and the second in $C^\perp$. Thus either $C=\mathbf{R}^n$, in which case $n=7$, or it is possible to find a unit vector $\mathbf{n}\in C^\perp$.

THEOREM. *If there exists a cross product on $\mathbf{R}^n$ which satisfies Apostol's axioms, then $n=1$, 3 or 7. Conversely, there exist cross products on these three spaces.*

Proof. We have seen that for $n\leqq 3$, cross products exist precisely when $n=1$ or 3, the cross product on $\mathbf{R}^1$ being identically zero and the two cross products on $\mathbf{R}^3$ being the classical ones, and that if $\mathbf{R}^n$ has a cross product for $n>3$, then $n\geqq 7$. If $n>7$, then one can find a unit vector $\mathbf{n}\in C^\perp$, where C is constructed as above. We shall show, however, that the existence of such a vector would lead to a contradiction. Indeed, should such an $\mathbf{n}$ exist, then $\mathbf{m}\times\mathbf{n}$ is also a unit vector in $C^\perp$; set $\mathbf{p}=\mathbf{m}\times\mathbf{n}$. Just as in Proposition 3, we have $\mathbf{n}\times\mathbf{p}=\mathbf{m}$ and $\mathbf{p}\times\mathbf{m}=\mathbf{n}$. Let us compute some products: we find that, for $i\neq j$,

$$
\begin{aligned}
&(\mathbf{e}_i \times \mathbf{m}) \times (\mathbf{e}_j \times \mathbf{n}) \\
&\quad = (\mathbf{e}_i \times \mathbf{m}) \times (\mathbf{e}_j \times (\mathbf{p} \times \mathbf{m})) \quad \text{by (4)} \\
&\quad = (\mathbf{e}_i \times \mathbf{m}) \times (\mathbf{m} \times (\mathbf{e}_j \times \mathbf{p})) \quad \text{by (4)} \\
&\quad = (\mathbf{e}_j \times \mathbf{p}) \times ((\mathbf{e}_i \times \mathbf{m}) \times \mathbf{m}) \\
&\quad = (\mathbf{e}_j \times \mathbf{p}) \times (\mathbf{m} \times (\mathbf{m} \times \mathbf{e}_i)) = (\mathbf{e}_j \times \mathbf{p}) \times [(\mathbf{m}\cdot\mathbf{e}_i)\mathbf{m} - (\mathbf{m}\cdot\mathbf{m})\mathbf{e}_i] \\
&\quad = -(\mathbf{e}_j \times \mathbf{p}) \times \mathbf{e}_i = \mathbf{e}_i \times (\mathbf{e}_j \times \mathbf{p}) = \mathbf{p} \times (\mathbf{e}_i \times \mathbf{e}_j).
\end{aligned}
$$

Similarly

$$
\begin{aligned}
(\mathbf{e}_j \times \mathbf{n}) \times (\mathbf{e}_i \times \mathbf{m}) &= \\
(\mathbf{e}_j \times \mathbf{n}) \times (\mathbf{e}_i \times (\mathbf{n} \times \mathbf{p})) &= \\
-(\mathbf{e}_j \times \mathbf{n}) \times (\mathbf{e}_i \times (\mathbf{p} \times \mathbf{n})) &= \quad \text{by (4)} \\
-(\mathbf{e}_j \times \mathbf{n}) \times (\mathbf{n} \times (\mathbf{e}_i \times \mathbf{p})) &= \quad \text{by (4)} \\
-(\mathbf{e}_i \times \mathbf{p}) \times ((\mathbf{e}_j \times \mathbf{n}) \times \mathbf{n}) &= \cdots \text{by (3)} \\
&= -(\mathbf{e}_i \times \mathbf{p}) \times (-\mathbf{e}_j) \\
&= \mathbf{p} \times (\mathbf{e}_i \times \mathbf{e}_j).
\end{aligned}
$$

(The computations indicated by the ellipsis are straightforward.) But putting these together gives $(\mathbf{e}_i \times \mathbf{m}) \times (\mathbf{e}_j \times \mathbf{n}) = (\mathbf{e}_j \times \mathbf{n}) \times (\mathbf{e}_i \times \mathbf{m})$; this contradicts the skew-symmetry of $\times$ unless this particular product is zero. However, $\mathbf{p} \times (\mathbf{e}_i \times \mathbf{e}_j)$ is the product of two perpendicular unit vectors and thus has unit norm. This contradiction shows that the case $n > 7$ cannot arise.

It remains to exhibit a cross product on $\mathbf{R}^7$ which satisfies the axioms. Such a product can be constructed from the familiar one on $\mathbf{R}^3$ as follows: $\mathbf{R}^7$ corresponds 1-1 with the set of all triples $(\mathbf{a}, \lambda, \mathbf{b})$ where $\mathbf{a}$ and $\mathbf{b}$ are in $\mathbf{R}^3$ and $\lambda \in \mathbf{R}$ under the correspondence

$$a_1\mathbf{i}_1 + \cdots + a_7\mathbf{i}_7 \to (a_1\mathbf{i} + a_2\mathbf{j} + a_3\mathbf{k},\ a_4,\ a_5\mathbf{i} + a_6\mathbf{j} + a_7\mathbf{k}).$$

It is easy to see that this correspondence turns addition and scalar multiplication in $\mathbf{R}^7$ into component-by-component addition and scalar multiplication of triples; defining the dot product of triples by

$$(\mathbf{a}_1, \lambda_1, \mathbf{b}_1)\cdot(\mathbf{a}_2, \lambda_2, \mathbf{b}_2) = (\mathbf{a}_1\cdot\mathbf{a}_2) + \lambda_1\lambda_2 + (\mathbf{b}_1\cdot\mathbf{b}_2)$$

we see easily that the dot product of two triples equals the dot product of the two elements of $\mathbf{R}^7$ to which they correspond. We actually define the cross product on these triples: if one recalls what Propositions 3 and 4 told one the multiplication table of C should be, and if one thinks of $(\mathbf{a}, \lambda, \mathbf{b})$ as representing a vector whose component in H is $\mathbf{a}$, whose component along $\mathbf{m}$ is λ, and whose component in the space spanned by $\{\mathbf{e}_1 \times \mathbf{m}, \mathbf{e}_2 \times \mathbf{m}, \mathbf{e}_3 \times \mathbf{m}\}$ is $\mathbf{b} \times \mathbf{m}$, then one is led to the definition

$$(\mathbf{a}_1, \lambda_1, \mathbf{b}_1) \times (\mathbf{a}_2, \lambda_2, \mathbf{b}_2) = ([\lambda_1\mathbf{b}_2 - \lambda_2\mathbf{b}_1 + (\mathbf{a}_1 \times \mathbf{a}_2) - (\mathbf{b}_1 \times \mathbf{b}_2)], [-(\mathbf{a}_1 \cdot \mathbf{b}_2) + (\mathbf{b}_1 \cdot \mathbf{a}_2)], [\lambda_2\mathbf{a}_1 - \lambda_1\mathbf{a}_2 - (\mathbf{a}_1 \times \mathbf{b}_2) - (\mathbf{b}_1 \times \mathbf{a}_2)]).$$

(Note that the cross products inside the brackets in the triple are products in $\mathbf{R}^3$ and thus well defined.) Knowing that the cross product in $\mathbf{R}^3$ satisfies the axioms, one easily verifies that this cross product on $\mathbf{R}^7$ (via identification of $\mathbf{R}^7$ with the triples) satisfies the axioms also. ∎

Remark: The pathological behavior of the cross product on $\mathbf{R}^7$ begins with its lack of anything near uniqueness: in $\mathbf{R}^3$ there are only two choices for the cross product of a given orthonormal pair of vectors, while in $\mathbf{R}^7$ our construction can be modified to yield cross products which choose any of the unit vectors in the five-dimensional space orthogonal to the given pair. The cross products on $\mathbf{R}^7$ also fail to satisfy the Lie identity

$$\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) + \mathbf{c} \times (\mathbf{a} \times \mathbf{b}) + \mathbf{b} \times (\mathbf{c} \times \mathbf{a}) = 0;$$

indeed

$$\mathbf{m} \times (\mathbf{e}_1 \times \mathbf{e}_2) + \mathbf{e}_2 \times (\mathbf{m} \times \mathbf{e}_1) + (\mathbf{e}_1 \times (\mathbf{e}_2 \times \mathbf{m})) = -3(\mathbf{e}_3 \times \mathbf{m}).$$

Any number of other standard identities also fail in $\mathbf{R}^7$.

Postscript. The discussion above has concentrated on the geometric problem of defining a cross product on a real inner product space, and has attacked this problem via reasoning processes close to those of three-dimensional vector geometry. The theorem it produces is actually equivalent to a classical theorem of Hurwitz which states that a bilinear "multiplication" operation (denoted by juxtaposition) with the property $|\mathbf{xy}| = |\mathbf{x}|\,|\mathbf{y}|$ can be introduced on a finite-dimensional real inner product space if and only if the space has dimension 1, 2, 4 or 8, and that the operation is then "essentially" the multiplication of the reals, complexes, Hamilton quaternions, or Cayley numbers, and actually is one of those multiplications if an identity is present. Indeed, assuming Hurwitz's theorem and being given an $\mathbf{R}^n$ with a cross product as before, write $\mathbf{R}^{n+1}$ as (isometric to) $\mathbf{R}\mathbf{e} \oplus \mathbf{R}^n$ where $\mathbf{e} \in \mathbf{R}^{n+1}$, and define a multiplication on $\mathbf{R}^{n+1}$ by

$$(\lambda\mathbf{e} + \mathbf{a})(\mu\mathbf{e} + \mathbf{b}) = (\lambda\mu - \mathbf{a} \cdot \mathbf{b})\mathbf{e} + (\mu\mathbf{a} + \lambda\mathbf{b} + \mathbf{a} \times \mathbf{b});$$

then it is easy to verify, using the cross product axioms, that this bilinear multiplication has the property $|\lambda\mathbf{e}+\mathbf{a}|\,|\mu\mathbf{e}+\mathbf{b}| = |(\lambda\mathbf{e}+\mathbf{a})(\mu\mathbf{e}+\mathbf{b})|$ and hence $n+1 = 2$, 4 or 8, $n = 1$, 3, or 7. On the other hand, Hurwitz's theorem follows quite readily from ours: given a real inner product space A with a multiplication satisfying $|\mathbf{xy}| = |\mathbf{x}|\,|\mathbf{y}|$ and a left-and-right identity $\mathbf{e}$, one finds that $(\mathbf{x} \cdot \mathbf{x})(\mathbf{y} \cdot \mathbf{y}) = (\mathbf{xy} \cdot \mathbf{xy})$ leads, after the usual couple of polarizations, to

$$2(\mathbf{z} \cdot \mathbf{x})(\mathbf{y} \cdot \mathbf{w}) = (\mathbf{zy} \cdot \mathbf{xw}) + (\mathbf{zw} \cdot \mathbf{xy}), \tag{5}$$

of which we shall need only the cases

$$(6,\ 6') \qquad (\mathbf{e}\cdot\mathbf{x})(\mathbf{y}\cdot\mathbf{y}) = (\mathbf{y}\cdot\mathbf{xy}), \qquad (\mathbf{x}\cdot\mathbf{x})(\mathbf{e}\cdot\mathbf{w}) = (\mathbf{x}\cdot\mathbf{xw})$$

and

$$(7) \qquad 2(\mathbf{z}\cdot\mathbf{e})(\mathbf{y}\cdot\mathbf{e}) = (\mathbf{zy}\cdot\mathbf{e}) + (\mathbf{z}\cdot\mathbf{y}).$$

Now let V denote the subspace $\mathbf{Re}^{\perp}$ of A, and define an operation $\times$ on V by $\mathbf{a}\times\mathbf{b} = \mathbf{ab} + (\mathbf{a}\cdot\mathbf{b})\mathbf{e}$.

Since $(\mathbf{a}\times\mathbf{b})\cdot\mathbf{e} = (\mathbf{ab}\cdot\mathbf{e}) + (\mathbf{a}\cdot\mathbf{b}) = 2(\mathbf{a}\cdot\mathbf{e})(\mathbf{b}\cdot\mathbf{e}) = 0$ by (7), $\times$ maps V bilinearly into itself, i.e. satisfies (5.29) and (5.30), and the version of (5.30) with λ applied to $\mathbf{b}$. It follows easily from (6) and (6′) that $(\mathbf{a}\times\mathbf{b})\cdot\mathbf{b} = 0 = \mathbf{a}\cdot(\mathbf{a}\times\mathbf{b})$, so (5.31) holds; moreover, it is not difficult to show from these two versions of (5.31) that (5.28) also holds. Finally, (5.32) follows quickly from (7). Thus by our theorem (which, it is easy to check, does not rest on finite-dimensionality hypotheses) V is 7, 3, 1 or possibly 0-dimensional, A is 8, 4, 2 or 1-dimensional, and quite easily seen to be isomorphic to the Cayley numbers, quaternions, complexes or reals. An elegant algebraic treatment of Hurwitz's theorem is to be found in [3].

Hurwitz's classical theorem suggests generalizations in various directions. We have noted in passing that (in the presence of an identity) finite dimensionality is a useless hypothesis; Wright [4] has shown that a nonassociative real normed division algebra with $|xy| = |x|\,|y|$ must actually have an inner-product norm, thus be one of our four standard algebras. A "nonassociative Gelfand-Mazur theorem," with merely $|xy| \leqq |x|\,|y|$, seems still to be lacking. In the situation of the classical Hurwitz theorem, the unit sphere of $\mathbb{R}^n$ ($n = 1, 2, 4$ or 8) comes equipped with a continuous product operation, with identity; a long series of profound topological results, culminating in [1], has shown that these values of n are the only ones for which such a continuous product on the unit sphere can exist.

The author thanks the referee for his suggestion that material be appended which would explicitly point out the relation of the preceding material to the Hurwitz theorem and to the recent topological results.

A COUNTEREXAMPLE TO TWO CONJECTURES IN IDEAL THEORY

R. W. GILMER, JR., Florida State University

This paper contains an example of an indecomposable one-dimensional ring T with identity which is not an integral domain and in which every ideal with prime radical is primary. (A commutative ring R is *n-dimensional* if there is a chain $P_1 \subset \cdots \subset P_{n+1}$ of prime ideals ($\neq R$) of R, but no such chain of $n+2$ prime ideals. Thus a field is 0-dimensional and the domain Z of ordinary integers is 1-dimensional.) The ring T provides a counterexample to a conjecture of Gilmer (page 78 of [1]). We also show that the zero ideal of T provides a counterexample to the following conjecture of Krull mentioned in [2; p. 733] and [3; p. 16]: If A is an ideal of the commutative ring R and if P is a maximal prime belonging to A, then P is a maximal prime ideal belonging to $A(P)$. (See [4; pp. 110, 187] for terminology and notation.) Nagata has also given a counterexample to this conjecture in [5].

To obtain the ring T, we let K be a field and we let $\{X_a\}_{a\in Q}$ be a set of indeterminates over K, where Q denotes the set of rational numbers. We set $D=K[\{X_a\}]$ and we let B be the ideal of D generated by the set $S=\{X_aX_b-X_a$ such that $a<b\}$. We show that $T=D/B$ is the required example.

T is a commutative ring with identity and we first show T is one-dimensional. If P is a proper prime ideal of D containing B there are two cases to consider:

CASE 1. Given $r\in Q$, $X_r\in P$ or $X_r-1\in P$. In this case P is maximal since $D/P\simeq K$.

CASE 2. There exists $r\in Q$ such that $X_r\notin P$, $X_r-1\notin P$. Then if $a<r$ we have $X_a(X_r-1)\in B\subseteq P$ so that $X_a\in P$ since P is prime. Similarly, if $a>r$, $X_a-1\in P$. It follows that

$$P \supseteq P_r = (N_r), \quad \text{where } N_r = \{\{X_a\}_{a<r}, \{X_a - 1\}_{a>r}\};$$

but $D/P_r\simeq K[X_r]$, and proper prime ideals of $K[X_r]$ are maximal. It then follows from elementary ideal theoretic properties of a ring homomorphism (for example, see Theorem 11, p. 151 of [6]) that either $P=P_r$ or P is maximal in D.

We conclude that T is one-dimensional and every nonmaximal prime ideal of T is of the form P_r/B for some $r\in Q$.

To show that every ideal of T with prime radical is primary it suffices to show that for $p\in P_r$, there exists $q_p\in P_r$ such that $p-pq_p\in B$ [1; p. 76]. First, if $p\in N_r$ then either $p=X_b$ where $b<r$, in which case we can take $q_p=X_d$ where $b<d<r$, or $p=X_b-1$ where $b>r$ and we take $q_p=1-X_d$ where $r<d<b$. Now observe that if $p_i-sp_i\in B$ for $1\leqq i\leqq k$ and if $p_{k+1}-tp_{k+1}\in B$, then $p_i-up_j\in B$ for $1\leqq j\leqq k+1$ where $u=s+t-st$.

It now follows by mathematical induction that if N is a finite subset of N_r, then there is an element $v\in P_r$ such that $p-pv\in B$ for each $p\in N$. Because N_r generates P_r, this condition also holds for arbitrary $p\in P_r$.

Finally, we show that the ring T is indecomposable; that is, we must show that 0 and 1 are the only idempotents of T. Because any algebraic relation $v^2 - v \in B$, where $v \in D$, can involve only finitely many of the indeterminates $\{X_a\}$, it suffices to show that if $S' = K[X_1, \cdots, X_n]$ and if B' is the ideal of S' generated by $\{X_i - X_j X_i\}_{i<j}$, then the ring $T' = S'/B'$ is indecomposable. This will follow if we can show B' is not representable as the intersection of two relatively prime ideals properly containing it. [6; p. 178]. We shall prove this on the basis of the following fact, which follows easily by induction:

If in S', P_i' is the prime ideal generated by

$$\{X_1, \cdots, X_{i-1}, X_{i+1} - 1, \cdots, X_n - 1\}, \quad \text{then } B' = \bigcap_{i=1}^{n} P_i'.$$

Now if we had $B' = C' \cap D' = C'D'$, where C' and D' are relatively prime ideals of S', then P_1' would contain one of C' or D', say $P_1' \supseteq C'$. Also $P_2' \supseteq C'$ or D'. But $P_1' + P_2' \subset S'$ and $C' + D' = S'$. Hence $P_2' \supseteq C'$. Then because $P_2' + P_3' \subset S'$, $P_3' \supseteq C'$, etc., so that $C' \subseteq B' \subseteq C'$. This completes the proof that the ring T', and therefore the ring T, is indecomposable.

Hence the ring T provides a counterexample to the conjecture of Gilmer cited previously.

We next note that if $r \in Q$, the ideal M_r generated by the set

$$\{X_a\}_{a \leqq r} \cup \{X_a - 1\}_{a > r}$$

is a maximal ideal of D containing P_r. Further, if

$$u = \sum_{i=1}^{t} b_i X_{a_i} + \sum_{i=1}^{s} c_i (X_{d_i} - 1) \in M_r$$

where $a_1 < \cdots < a_t \leqq r < d_1 < \cdots < d_s$ and if $d \in Q$ is such that $r < d < d_1$, then $X_d^2 - X_d \notin B$ (since D/B is indecomposable) and $u(X_d^2 - X_d) \in B$. This shows that M_r is a maximal prime belonging to B. But $B(M_r) = P_r$ since we always have $B(M_r) \subseteq P_r$ and in this case we have previously proved that given $p \in P_r$, there exists $q_p \in P_r$ such that $p(q_p - 1) \in B$. Now $q_p \in P_r$ implies $q_p - 1 \notin M_r$ so that $p \in B(M_r)$. Consequently $P_r = B(M_r)$ and M_r is not a prime belonging to $B(M_r)$. These observations show that the ideal B of D or the ideal (0) of T provides a counterexample to Krull's conjecture mentioned earlier.

Our proof above shows clearly what conditions are necessary in order that Krull's conjecture hold in a one-dimensional ring R in which each ideal with prime radical is primary. Namely, it is necessary and sufficient that every maximal ideal of height one contain a regular element. This statement then represents a partial converse to Theorem 2 of [1].

As a final remark, we observe that if M' is the ideal of D generated by $\{X_a\}_{a \in Q}$, M' is a minimal prime ideal of B. Yet we have already shown $B = \sqrt{B} = \bigcap_{r \in Q} P_r$.

Hence B is semi-prime but has imbedded prime components. Nagata gave an example of a semi-prime ideal with this property in [5].

PROBLEMS AND SOLUTIONS

EDITED BY E. P. STARKE

COLLABORATING EDITORS: J. BARLAZ, Rutgers—The State University; L. CARLITZ, Duke University; HASKELL COHEN, Louisiana State University; H. EVES, University of Maine; M. S. KLAMKIN, Ford Scientific Laboratory; R. C. LYNDON, University of Michigan; and A. WILANSKY, Lehigh University.

All problems (both elementary and advanced) proposed for inclusion in this Department should be sent to E. P. Starke, 1000 Kensington Ave., Plainfield, N. J. 07060. Proposers of problems are urged to enclose any solutions or information that will assist the editors. Ordinarily, problems in well-known textbooks and results in generally accessible sources are not appropriate for this Department. No solutions (except those accompanying proposals) should be sent to Professor Starke.

ELEMENTARY PROBLEMS

Solutions of Elementary Problems should be sent to M. S. Klamkin, Ford Scientific Laboratory, P. O. Box 2053, Dearborn, Mich. 48121. To facilitate their consideration, solutions for Elementary Problems in this issue should be submitted legibly on separate, signed sheets and should be mailed before June 30, 1967. Any contributor wishing acknowledgement of his solution should include a self-addressed, stamped postcard. (Solvers outside the United States may omit the stamp.)

E 1955. *Proposed by D. J. Newman, Yeshiva University*

Suppose $x_{n+1}=x_n+1/(x_1+x_2+\cdots+x_n)$ and that $x_1=1$ (thus $x_2=2$, $x_3=7/3$, $x_4=121/48$, $\cdots$). Prove that $x_n\sim\sqrt{2\log n}$.

E 1956. *Proposed by R. Sivaramakrishnan, Government Engineering College, Trichur, India*

Let a, b, c be the sides of a triangle ABC, and let R, r, r_1, r_2, r_3 be the circumradius, inradius, and exradii, and h_i $(i=1, 2, 3)$ be the altitudes from A, B, C to the opposite sides. Prove that

1. $$\frac{h_1}{bcr_1}+\frac{h_2}{car_2}+\frac{h_3}{abr_3}=\frac{1}{2R\cdot r},$$

2. $$\frac{h_1+r_1}{bcr_1}+\frac{h_2+r_2}{car_2}+\frac{h_3+r_3}{abr_3}=\frac{1}{R\cdot r}.$$

E 1957. *Proposed by C. C. Lindner, Coker College, Hartsville, S. C.*

Can the accompanying table be completed to a group table without placing x_1 again on the principal diagonal, where the ith row and ith column are both headed by x_i?

$\vdots$						
x_n						

E 1958. *Proposed by S. R. Petrick, Air Force Cambridge Research Laboratories*

Find a point P in the plane of the triangle ABC such that

$$\min\{|PA-PB|, |PB-PC|, |PC-PA|\}$$

is maximized and determine the value of this maximum.

E 1959. *Proposed by R. A. Struble, North Carolina State University*

If $f(x, y)\in C^1$ and is periodic in x with least (positive) period $P(y)$, then the partial derivative $f_y(x, y)$ is periodic if and only if $P'(y)=0$.

E 1960. *Proposed by Erwin Just, Bronx Community College*

Prove that the numerator of the fraction determined by $\sum_{k=0}^{2^n-1} 1/(2k+1)^m$, where m is an odd integer, is divisible by 2^{n+1}.

E 1961. *Proposed by L. M. Graves, Chicago, Ill.*

Note that $18\cdot 6=108$, $15\cdot 7=105$, $45\cdot 9=405$. Find all bases α other than 10 for which there exist triples (a, b, c) of digits with a corresponding property: $(\alpha a+b)c=\alpha^2 a+b$, where $0<a<\alpha$, $1<b<\alpha$, $1<c<\alpha$. Also find, for each α, the number of such triples, or a lower bound for the number.

E 1962. *Proposed by R. Sivaramakrishnan, Government Engineering College, Trichur, India*

If $\phi(n)$ denotes Euler's phi-function and $\tau(n)$ is the number of divisors of n, prove that $\phi(n)\tau(n)\geqq n$.

E 1963. *Proposed by Jack C. Abad, City College of San Francisco*

For whole numbers q and n define $S_q(0)=1$, $S_q(n+1)=q^{S_q(n)}$. Find the greatest power of 2 that will divide $S_3(n+1)-S_3(n)$.

E 1964. *Proposed by Erwin Just, Bronx Community College*

Let $\{m_i\}$ be the set of $\phi(m)$ positive integers which are less than m and relatively prime to m. If $m>2$, prove that $\sum_{i=1}^{\phi(m)} 1/m_i$ is not an integer.

SOLUTIONS OF ELEMENTARY PROBLEMS

Notice by the Editors. Six months of effort have failed to produce the files of correspondence regarding Solutions of Elementary Problems sent to the Editors since about March 25, 1966. It will be greatly appreciated if readers (including the proposers) who submitted solutions for problems E 1835 through E 1894 would find it possible to send duplicate solutions as soon as possible directly to E. P. Starke, 1000 Kensington Ave., Plainfield, N. J. 07060.

Ring Axioms

E 1812 [1965, 782]. *Proposed by Samuel Stern, State University College, Buffalo, N. Y.*

Let R be a set satisfying all ring axioms, omitting commutativity of addition. If R has a right multiplicative identity prove that R is a ring.

Solution by David M. Cohen, Tenth grade student, Central High School, Philadelphia, Pa. Let e be the right multiplicative identity. We have

$$0 = b[e + (-e)] = b(e) + b(-e) = b + b(-e). \tag{1}$$

Therefore $-b=b(-e)$.

$$0=(-b)+(-a)+a+b=b(-e)+a(-e)+a+b=(b+a)(-e)+a+b. \tag{2}$$

Therefore $a+b=-[(b+a)(-e)]$.

$$(b+a)+(b+a)(-e)=(b+a)(e)+(b+a)(-e)=(b+a)[(e)+(-e)]=0. \tag{3}$$

Therefore $b+a=-[(b+a)(-e)]$.

Hence $a+b=b+a$, completing the proof.

Also solved by R. G. Albert, George Alberts, L. R. Anderson, R. A. Avelsgaard, P. N. Bajaj, T. L. Bartlow, D. A. Blaeuer, A. K. Bose, J. V. Bou, H. G. Bray, F. S. Brenneman, J. L. Brown, Jr., S. I. Brown, A. B. Carter, P. L. Chabot, Gregory Cherlin, D. I. A. Cohen, J. K. Cole, C. R. Conniff, C. G. Cullen, R. D. Davis, M. J. DeLeon, J. F. Dillon, C. W. Dodge, J. W. Duke, E. W. Ewing, J. L. Faix, R. A. Feinman, R. W. Feldmann, Neal Felsinger, N. J. Fine, K. G. Fischer, John Ganci, P. K. Garlick, Tina Handelman, R. B. Hardin, Jr., W. E. Hoff, G. T. Hogan, J. E. Homer, Jr., Colonel Johnson, Jr., Erwin Just, P. C. Kainen, B. C. Klein, Max Klicker, Kenneth Kramer, Daryl Kreiling, E. S. Langford, Milton Legg, R. N. Leggett, Jr., Steven Ligh, C. C. Lindner, G. J. Lubrano, R. E. Maas, C. F. Marion, D. C. B. Marsh, J. J. Martinez, W. E. Mastrocola, J. T. Mathis, C. J. Maxson, J. M. McGuinness, M. R. Meck, Helen Merkel, Michael Merscher, J. J. More, G. S. Musser, Barbara W. Nason, R. W. Neufeld, John Nichols, L. D. Olson, C. B. A. Peck, Harsh Pittie, Richard Poss, Bob Prielipp, Alfred Raws III, J. T. Renfrow, Henry Ricardo,

Azriel Rosenfeld, Nina M. Roy, B. D. Rudin, L. O. Rush, P. S. Schnare, R. N. Schneider, Claude Schochet, Gerald Schrag, G. F. Schumm, Robin Sibson (England), David A. Smith, John M. Smith, LaRon Smith, Al Somayajulu, L. E. Spence, Robert Spira, Preston Stein, Margaret W. Taft, Elaine Tatham, T. K. Teague, E. W. Wallace, F. T. Walsh, A. Wilansky, C. R. Williams, Dale Woods, Paul Yang, K. L. Yocom, and the proposer.

C. J. Maxson points out that the problem was solved by Berman and Silverman [*Near Rings*, this MONTHLY, 66 (1959) 23–34] requiring (instead of the existence of e) only that every element of R be a product of two elements of R. R. A. Feinman shows that the conclusion still holds when the hypothesis is relaxed by permitting non-associative multiplication and asking only that R contain an element which is not a right divisor of zero. Other readers found essentially the same problem in seven current textbooks.

A Row Semi-magic Square

E 1813 [1965, 782]. *Proposed by Milton Legg, University of Minnesota, Duluth*

Let A be a row semi-magic square and let A_j denote the matrix obtained by replacing the jth column of A by a column of 1's. Show that $\det(A_j)$ is independent of j.

Solution by J. Wesley, Union College, Barbourville, Ky. In A_i let all columns except the ith be added to the jth, $j \neq i$. This gives for the jth column of A_i the elements $k-a_{1i}, k-a_{2i}, \cdots, k-a_{ni}$, where k is the magic number. Expanding by this column splits A_i into two determinants, one of them vanishing. In the other, transposing the ith and jth columns gives $\det(A_i)=\det(A_j)$.

Also solved by R. F. Jackson, E. S. Langford, Simeon Reich (Israel), Robin Sibson (England), Sidney Spital, and K. L. Yocom.

Fourteen other correspondents added to the jth column of A all the other columns, obtaining $\det(A)=k \det(A_j)$, and concluded that $\det(A_j)$ is constant. This proof is inconclusive in case $k=0$.

Sums of Two Squares

E 1814 [1965, 782]. *Proposed by R. C. Thompson, University of California, Santa Barbara*

Show that there exist infinitely many sets of three consecutive integers, each of which is a sum of two squares of positive integers.

I. *Solution by W. J. Blundon, Memorial University of Newfoundland.* There is at least one n (e.g. $n=72$) such that n, $n+1$, $n+2$ are each sums of two positive squares. From any such set we may obtain another, larger, set. In fact, if $n=a^2+b^2$, $n+1=c^2+d^2$, $n+2=e^2+f^2$, we have

$$n^2+2n=(af-be)^2+(ae+bf)^2,$$

$$n^2+2n+1=(c^2-d^2)^2+(2cd)^2,$$

$$n^2+2n+2=(n+1)^2+1^2.$$

Iteration of this process will produce as many sets as desired.

II. *Solution by P. N. Nagara, Kasetsart University, Bangkok, Thailand.* It is easily verified that

$$(17b - 1)^2 + (34b - 2), \qquad (15b)^2 + (8b)^2, \qquad (17b)^2 + 1^2$$

are consecutive integers. The problem is solved for all b such that $34b - 2 = (2n)^2$ or $b = (2n^2+1)/17$. Now b will be integral when $n = 17a \pm 5$ for all a.

III. *Solution by Maxey Brooke, Sweeny, Texas.* Math. Quest. Educ. Times (2), 3 (1903) 41–43 shows that $(2n)^2+(2n)^2$, $8n^2+1$, and $(2n-1)^2+(2n+1)^2$ are such a triple if n is any triangular number $n = (m^2+m)/2$. See also Dickson, *History of the Theory of Numbers*, II, p. 252.

Also solved by Leon Bankoff, E. Beck (Germany), M. T. L. Bizley (England), D. I. A. Cohen, G. C. Dodds, R. B. Eggleton (Australia), N. J. Fine, Michael Goldberg, M. L. Goodman, Cornelius Groenewoud, Wallace Growney, M. A. Jacobs, Sam Kravitz, Sidney Kravitz, Kent Kromarek, R. C. Lyness (England), C. F. Marion, D. C. B. Marsh, J. J. Martinez, G. F., Melendy, Norman Miller, F. D. Parker, Walter Penney, Robin Sibson (England), D. L. Silverman, G. C. Thompson, E. W. Trost (Switzerland), Benjamin Volk, J. Wesley, J. W. Wilson, Dale Woods, K. L. Yocom, and the proposer.

Note that, of any four consecutive integers, at least one is not representable as the sum of two squares, since it will be of form $4k-1$.

A Pairing Problem

E 1815 [1965, 902]. *Proposed by D. M. Paine, Wells College, Aurora, N. Y.*

Can $2n$ people be paired differently on $2n-1$ occasions, so that each is paired with each other on exactly one occasion?

Solution by Maxey Brooke, Sweeny, Texas. This is a modification of Kirkman's Schoolgirl Problem (*Ladies' and Gentlemen's Diary*, 1850, p. 48). One solution is to put 1 in the center of a circle and the other $2n-1$ numbers equally spaced around the circumference. Draw a diameter through one number and pair the other numbers with chords perpendicular to this diameter. The points located on the diameter and chords are one arrangement. Distinct arrangements are obtained corresponding to each such diameter. M. Kraitchek, *Mathematical Recreations*, Dover, 1942, pp. 226–227, discusses this problem in detail.

Also solved by E. P. Berger & W. J. Conover, L. J. Burton, P. J. Campbell, Gary Chartrand, Jane W. Di Paola, P. M. Ellis, R. P. Farrell, R. P. Fiske, Michael Goldberg, M. L. Goodman, Dale Griffith, D. E. Helton, J. E. Homer, Jr., Erwin Just, Kenneth Kramer & Joel Spruck, R. N. Leggett, Jr., F. W. Lozier, Charles McCracken & J. C. Koegler, R. E. Maas, Lieselotte Miller, J. J. More, P. J. Nyikos, F. D. Parker, C. B. A. Peck, Walter Penney, Harsh Pittie, Walter Sadler, J. S. Scandale, Jr., R. W. Shoemaker, Walter Stromquist, R. G. Thompson, Simon Vatriquant (Belgium), R. J. Walker, J. J. Weinkam, John Wessner, and the proposer.

For other references see J. E. Freund, *Round Robin Mathematics*, this MONTHLY, 63(1956) 112–114; O. Ore, *Graphs and their Uses*, p. 50. Farrell would like to know how many distinct solutions are there of the problem. For a similar problem see E 208 [1938, 479].

An Inequality Related to Stirling's Formula

E 1816 [1965, 902]. *Proposed by J. Garfunkel, Brooklyn, N. Y.* For $n>1$, prove

$$(n!)! > [(n-1)!]^{n!}.$$

Solution by Harsh Pittie, Swarthmore College. The inequality

$$\sum_{k=2}^{m} \log k > \int_1^m \log x dx, \quad m > 2$$

gives us $m! > m^m e^{1-m}$, so that $n^m m! > m^m e(n/e)^m$. Replacing m by $n!$ we obtain the sharpened inequality

$$(n!)! > [(n-1)!]^{n!} \cdot e(n/e)^{n!}.$$

Also solved by Larry Armi & Larry Martin, R. A. Bell, D. G. Beverage, N. P. Bhatia, L. J. Burton, P. J. Campbell, John Christopher, D. D. Culbertson, J. A. Donaldson, R. V. Esperti, R. S. Farrell, J. A. Faucher, Hyman Gabai, P. K. Garlick, Jerry Goodman, D. M. Hancasky, Bill Helliwell, Erwin Just, Kenneth Kramer & Joel Spruck, D. C. B. Marsh, J. J. More, Barbara W. Nason, P. J. Nyikos, C. B. A. Peck, L. A. Ringenberg, A. W. Roberts, J. S. Scandale, Jr., P. S. Schnare, R. Shantaram, Richard Sinkhorn, Al Somayajulu, R. P. Soni, G. P. Speck, Sidney Spital, Preston Stein, Raymond Struble, C. Van de Vyle (Belgium), John Vinson & Bob Juola, Benjamin Volk, J. J. Weinkam, J. Wesley, Dean West, L. R. Wirak, So Chul Yang, K. L. Yocom, Leonard Yonis, and the proposer.

Bhatia, Juola and Vinson obtain the result in the form

$$(n!)! > [(n-1)!]![(n-1)!]^{n!}, \quad n > 1.$$

Campbell makes use of E 1777 [1965, 420]. Marsh uses Mitrinović, *Elementary Inequalities*, 3.16, p. 85–86.

A Divisibility Problem

E 1817 [1965, 902]. *Proposed by C. F. Blackmore, University of Arkansas*

Let $r=(2n+1)^k$, where n and k are nonnegative integers. Show that, for any integer a, $a^r+(a+1)^r+\cdots+(a+2n)^r$ is always divisible by $(2n+1)^{k+1}$.

Solution by D. C. B. Marsh, Colorado School of Mines. This is a consequence of a result from number theory (easily proved by induction on k): For every nonnegative integer k, $a \equiv b \pmod{m}$ implies

$$a^{m^k} \equiv b^{m^k} \pmod{m^{k+1}}. \tag{1}$$

For $r=(2n+1)^k$ and $f(a)=a^r+(a+1)^r+\cdots+(a+2n)^r$, we have

$$f(a+1)-f(a) = (a+2n+1)^r - a^r \equiv 0 \pmod{(2n+1)^{k+1}} \tag{2}$$

by (1). With r odd, $f(-n)=(-n)^r+(-n+1)^r+\cdots+(n-1)^r+n^r=0$ is divisible by $(2n+1)^{k+1}$, whence (2) implies that $f(a)$ is divisible by $(2n+1)^{k+1}$ for every integer a.

Also solved by L. J. Burton, Carey Jensen, Erwin Just, John Keesee, Felix Magnotta, and C. Van de Vyle (Belgium).

An Equiangular Octagon

E 1818 [1965, 902]. *Proposed by I. J. Schoenberg, University of Wisconsin*

Let $A_0A_1 \cdots A_7A_0$ be a convex octagon in the plane having all its angles equal. Show that, if all the sides A_jA_{j+1} ($j=0, 1, \cdots, 7$; $A_8=A_0$) are commensurable, then opposite sides must be equal in pairs, i.e. $A_jA_{j+1}=A_{j+4}A_{j+5}$ ($j=0, 1, 2, 3$).

Solution by Michael Goldberg, Washington, D. C. Let the lengths of the sides be a, b, c, d, e, f, g, h. Then the components parallel to the side a must satisfy the equation

$$h/\sqrt{2} + a + b/\sqrt{2} = f/\sqrt{2} + e + d/\sqrt{2},$$

since each angle is 145°. Hence $(h+b-f-d)/\sqrt{2}=e-a$. If the sides are commensurable, then each member of the equation must be zero since $\sqrt{2}$ is irrational. Hence $e=a$. By symmetry, $f=b$, $g=c$, $h=d$.

Also solved by P. N. Bajaj, Mary B. Bridgham, John Burslem, D. M. Hancasky, Ned Harrell, Robert Maas, D. C. B. Marsh, C. B. A. Peck, L. A. Ringenberg, Sidney Spital, Walter Stromquist, C. Van de Vyle (Belgium), Simon Vatriquant (Belgium), William Wernick, and the proposer.

Probability in an Arrangement of Two Kinds of Elements

E 1819 [1965, 902]. *Proposed by V. K. Rohatgi, The University, Sheffield, England*

Let p, q, k be positive integers such that $pk<q$. Consider a sequence consisting of p plus ones and q minus ones in a random arrangement. Find the probability that at some point in the sequence the number of minus ones up to that point is less than k times the number of plus ones up to that point.

Solution by the proposer. There are $\binom{p+q}{q}$ possible arrangements in all. It suffices to count all possible arrangements in which the number of minus ones at some point is at least k times the number of plus ones up to that point. Noting that the last element in such arrangements could either be a plus one or a minus one it can be shown by induction that there are $r\binom{p+q}{q}$ such arrangements, where $r=(q+1-kp)/(q+1)$. Hence the required probability is $1-r=kp/(q+1)$.

This problem is a variant of the famous Bertrand Ballot Theorem [1, 66] generalized in [2]. It is also a direct generalization of an urn problem solved in [3] where a short historical account may be found.

1. W. Feller, *An Introduction to Probability Theory and its Applications*, vol. I (2nd ed.), 1957.

2. L. Takács, *A generalisation of the ballot problem and its application in the theory of queues*, J. of the Amer. Statistical Assn., 57 (1962) 327–337.

3. SIAM Review, vol. 7, No. 1 (1965) 136.

Also solved by Sidney Spital who employs Theorem 2 of A. Dvoretzky and T. Motzkin, *A problem of arrangements*, Duke Math. J., 14 (1947) 308.

II. *Solution by Ted Aldrich, Western Reserve University.* Define $a_0 = -\infty$, $a_{n+1} = +\infty$, then for k such that $a_{k-1} < x \leqq a_k$, $k \in \{1, 2, \cdots, n+1\}$, we may take

$$f(x) = \tfrac{1}{2}(f_k(x) + b_k) + \tfrac{1}{2}(-1)^{2H}(f_k(x) - b_k),$$

where the argument of H is $\prod_{i=1}^{n}(x - a_i)$.

Also solved by J. T. Burke, George Cherlin, J. A. Donaldson, R. B. Eggleton (Australia), P. K. Garlick, R. L. Farrell, F. N. Fritsch, Michael Goldberg, F. W. Keene, Kenneth Kramer, J. E. McKenna, Beatriz Margolis, D. C. B. Marsh, Steven Minsker, C. B. A. Peck, Donald Quiring, G. S. Rogers, Walter Sadler, P. A. Scheinok, John Vinson, C. Van de Vyle (Belgium), and Anders Vretblad (Sweden).

A Determinant of Binomial Expansions

E 1823 [1965, 903]. *Proposed by W. C. Brady, Washington and Jefferson College*

Show that

$$\begin{vmatrix} (a_0 + b_0)^n & (a_0 + b_1)^n \cdots (a_0 + b_n)^n \\ (a_1 + b_0)^n & (a_1 + b_1)^n \cdots (a_1 + b_n)^n \\ \cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots \\ (a_n + b_0)^n & (a_n + b_1)^n \cdots (a_n + b_n)^n \end{vmatrix} = (-1)^{n(n+1)/2} \prod_{j=0}^{n} \binom{n}{j} \prod_{\substack{j<i \\ i=0}}^{n} (a_i - a_j)(b_i - b_j).$$

Solution by P. G. Kirmser, Kansas State University. Let the determinant to be evaluated by Δ, and replace its ijth element with $\sum_{k=0}^{n} \binom{n}{k} a_{i-1}^{k} b_{j-1}^{n-k}$. Then, by the multiplication rule we can write

$$\Delta = \begin{vmatrix} 1 & a_0 & a_0^2 \cdots a_0^n \\ 1 & a_1 & a_1^2 \cdots a_1^n \\ \cdots & \cdots & \cdots\cdots \\ 1 & a_n & a_n^2 \cdots a_n^n \end{vmatrix} \cdot \begin{vmatrix} \binom{n}{0} b_0^n & \binom{n}{0} b_1^n & \cdots \binom{n}{0} b_n^n \\ \binom{n}{1} b_0^{n-1} & \binom{n}{1} b_1^{n-1} & \cdots \binom{n}{1} b_n^{n-1} \\ \cdots\cdots\cdots & \cdots\cdots\cdots & \cdots\cdots\cdots \\ \binom{n}{n} b_0^0 & \binom{n}{n} b_1^0 & \cdots \binom{n}{n} b_n^0 \end{vmatrix}.$$

If we reverse the order of columns in the first of these determinants, thereby multiplying it by $(-1)^{n(n+1)/2}$, and remove the binomial coefficient factors in the rows of the second, we have the well-known Vandermonde determinants. Hence the result as stated.

Also solved by P. N. Bajaj, P. K. Garlick, J. E. Homer, Jr., D. C. B. Marsh, Sidney Spital, Benjamin Volk, and the proposer.

An Easy Consequence of Fermat's Theorem

E 1824 [1965, 903]. *Proposed by Douglas Lind, Falls Church, Va.*

Let $p_1, p_2, \cdots, p_n$ be n primes, not necessarily distinct, let $p^{(n)}$ be the product of these primes, and let p' be the integer

$$p' = p^{(n)}(1 - 1/p_1 - 1/p_2 - \cdots - 1/p_n).$$

Prove that

$$\frac{x^{p_n}}{p_n} + \frac{x^{p_n \cdot 1}}{p_{n-1}} + \cdots + \frac{x^{p_1}}{p_1} + \frac{p'x}{p^{(n)}}$$

is an integer for all integral x.

Solution by Harsh Pittie, Swarthmore College. Substituting the expression for p', the sum becomes

$$x + \sum_{k=1}^{n} \frac{x(x^{p_k-1}-1)}{p_k}.$$

Each term in the summation is an integer; for, either $p_k \mid x$, or by Fermat's theorem, $x^{p_k-1} \equiv 1 \pmod{p_k}$. If x is a negative integer no difficulty is encountered.

Also solved by Joseph Arkin, José Asseo, Homer Bechtell, John Burslem, John Christopher, J. A. Donaldson, Ragnar Dybvik (Norway), R. B. Eggleton (Australia), P. K. Garlick, Ray Glenn, Michael Goldberg, Jerry Goodman, A. S. Howard, Erwin Just, Kenneth Kramer, Marijo LeVan, D. C. B. Marsh, J. T. Mathis, Donald Quiring, P. A. Scheinok, Al Somayajulu, Sidney Spital, Preston Stein, A. M. Vaidya (India), C. Van de Vyle (Belgium), Simon Vatriquant (Belgium), John Vinson, Benjamin Volk, J. J. Weinkam, K. L. Yocom, David Zeitlin, and the proposer.

ADVANCED PROBLEMS

All solutions of Advanced Problems should be sent to J. Barlaz, Rutgers—The State University, New Brunswick, N. J. 08903. Solutions of advanced problems in this issue should be submitted on separate, signed sheets and should be mailed before August 31, 1967. Any contributor wishing acknowledgement of his solution should include a self-addressed stamped postcard. (Solvers outside the United States may omit the stamp.)

5460. *Proposed by Adriano Behrmann, Sao Paulo, Brazil*

Prove the following series expansion for the Euler constant:

$$C = \frac{1}{2} + \sum_{n=2}^{\infty} \frac{a_n}{(2n-2)(2n-1)(2n)},$$

where a_n satisfies $2^{a_n} < 2n-1 < 2^{a_n+1}$. Compare 4353 [1951, 116].

5461. *Proposed by M. S. Klamkin, Ford Scientific Laboratory*

Show that it is possible in E_n to have $n+1$ mutually orthogonal spheres. What is the maximum number of such spheres?

5462. *Proposed by W. A. McWorter, University of British Columbia*

A finite ring is a field if and only if it has at most one nilpotent and at most two idempotents.

5463. *Proposed by W. G. Spohn, Jr., Applied Physics Laboratory, Johns Hopkins University*

For $n=2, 4, 6, \cdots$, define $f_n(x)=\log(1+x^n)$. Prove $f_n^{(n)}(-1)=0$.

5464. *Proposed by C. M. Petty and W. E. Johnson, Lockheed Aerospace Sciences Laboratory*

If A is a normal matrix (i.e., A commutes with its conjugate transpose), then the characteristic roots of A form a symmetric set with respect to the origin in the complex plane (i.e. if Z is a characteristic root of multiplicity r then $-Z$ is a characteristic root of multiplicity r) if and only if the trace $(A^{2k+1})=0$ for $k=0, 1, 2, \cdots$.

5465. *Proposed by M. S. Klamkin, Ford Scientific Laboratory*

It is a known result that an equilateral triangle cannot be imbedded in a square lattice but that it can be done in a cubic lattice. If in the latter case, one of the vertices is at the origin (0, 0, 0), determine all possible coordinates for the other pair of vertices.

5466. *Proposed by Benjamin Volk, Yeshiva University*

Discuss the convergence, as $x\to\infty$, of

$$\sum_{n\leq x}\frac{1}{n}\left(\sin\frac{x}{n}+\sin\frac{n}{x}\right).$$

Cf. 5203 [1965, 559].

5467. *Proposed by M. V. Subbarao, University of Alberta*

If $|x|<1$, prove that

$$x\left(\frac{1+x}{1-x}\right)+2x^4\left(\frac{1+x^2}{1-x^2}\right)+3x^9\left(\frac{1+x^3}{1-x^3}\right)+\cdots+nx^{n^2}\left(\frac{1+x^n}{1-x^n}\right)+\cdots$$
$$=x\frac{1-x}{(1-x)^2}+x^2\frac{(1-x^4)}{(1-x^2)^2}+x^3\frac{(1-x^9)}{(1-x^3)^2}+\cdots+x^n\frac{(1-x^{n^2})}{(1-x^n)^2}+\cdots.$$

5468. *Proposed by S. W. Williams, Lehigh University*

A subset S of a linear space is called *radial at a point* x if and only if S contains a line segment through x in every direction. A set S is *radially open* if it is radial at each of its points. Let T be the collection of radially open sets in the plane R^2. Show that the topological space (R^2, T) formed by T is separable, but neither Lindelöf, first countable, nor normal. Is it regular?

5469. *Proposed by Charles Green, University of Maine*

Let Z_m be the ring of integers modulo the composite integer m, and let k be a proper factor of m. Then $I=\{x\in Z_m: \bar{k}x=\bar{0}\}$ is an ideal in Z_m. Find necessary and sufficient conditions that I be a field; if it is, characterize the identity.

SOLUTIONS OF ADVANCED PROBLEMS

Correction: Problem 5333 [1966, 1022]. In the last line p. 1023, replace $x-g$ by xg.

Linearly Independent Sets over Countable Subfields

5344 [1965, 1135]. *Proposed by Ben Fitzpatrick, Jr., Auburn University, Alabama*

In proving that a subset of E_n is n-dimensional if and only if it contains a nonempty open subset of E_n, Hurewicz and Wallman (*Dimension Theory*, p. 45) use the intuitively appealing statement that if X and Y are two countable subsets of E_n, "it is always possible to choose the coordinate system so that the axes are in general position (no parallel to a coordinate hyperplane contains more than one point x or one point y) since this condition requires the axes to avoid at most a countable number of directions." Verify the following proposition and show that it implies their statement.

If K is a countable subfield of the field of complex (real) numbers and n is a positive integer, $n>1$, then there exists an $n\times n$ unitary (orthogonal) matrix P such that for each $i=1, \cdots, n$, the elements of the ith row of P are linearly independent over K.

Solution by the proposer. Let S denote the space of all $n\times n$ unitary (orthogonal) matrices, with metric

$$d(A, B) = \left(\sum_{i,j=1}^{n} | a_{ij} - b_{ij} |^2 \right)^{1/2}.$$

Then (S, d) is a complete metric space. Let G denote the collection to which the n-term sequence $\alpha=(\alpha_1, \cdots, \alpha_n)$ belongs if and only if $\alpha_i\in K$ for each $i=1, \cdots, n$, and $\sum_{i=1}^{n}|\alpha_i| \neq 0$. The collection G is countable. For each $\alpha\in G$ and each $i=1, \cdots, n$, denote by $U(\alpha, i)$ the set of all matrices P of S such that $\sum_{j=1}^{n}\alpha_j p_{ij}\neq 0$. It follows that each $U(\alpha, i)$ is open and dense in S. Then $\cap U(\alpha, i)$, the intersection being taken over all integers $i=1, \cdots, n$ and over all elements of G, is the intersection of countably many dense open sets in a complete metric space and thus is dense in S. Let P be an element of this intersection. Then P is the desired unitary (orthogonal) matrix.

Now suppose X and Y are countable subsets of E_n, as is also $X\cup Y$. Let L denote the set of all real numbers α such that $\alpha=s_i-t_i$ for some $i=1, \cdots, n$ and some s and t in $X\cup Y$. Then L is countable and is thus a subset of a countable subfield K of the reals. Consider an orthogonal matrix P as in the proposi-

tion above. Now if the images of two distinct points s and t under the orthogonal transformation P have the same ith coordinate for some $i=1, \cdots, n$, we have a linear combination of the elements of the ith row of P equaling 0, where the scalar multipliers are in L and hence in K.

About $\Sigma 1/n$

5346 [1965, 1136]. *Proposed by Louis Comtet, Boulogne (Seine), France*

Let $s(n)=1+\frac{1}{2}+\frac{1}{3}+\cdots+1/n$; for each $x\geqq 1$, define $n(x)$ by: $s(n(x))\leqq x<s(n(x)+1)$. With the notations: $E(x)=\exp(x-\gamma)-\frac{1}{2}$, ($\gamma=0.57\cdots$ is the Euler constant), $\alpha(x)=1/(\exp(x-1)-1)$, $[u]=$integral part of u; if $x\geqq 2$, prove that

$$\left[E(x)-\frac{3}{2}\alpha(x)\right]\leqq n(x)\leqq\left[E(x)+\frac{1}{12}\alpha(x)\right].$$

(N.B., if $x\geqq 2$, then $\frac{1}{12}\alpha(x)+\frac{3}{2}\alpha(x)<1$, and the formula gives at most two possible values for $n(x)$.)

Solution by the proposer. From the Euler-Maclaurin formula we obtain

$$\log(n)+\gamma+\frac{1}{2n}-\frac{1}{12n^2}\leqq s(n)\leqq\log(n)+\gamma+\frac{1}{2n};$$

consequently, with $n=n(x)$,

$$\log(n)+\gamma+\frac{1}{2n}-\frac{1}{12n^2}\leqq s(n)\leqq x<s(n+1)\leqq\log(n+1)+\gamma+\frac{1}{2(n+1)}.$$

It therefore follows that

$$n\Phi(n)\equiv n\exp\left(\frac{1}{2n}-\frac{1}{12n^2}\right)<\exp(x-\gamma)$$
$$<n\exp\left(\frac{3}{2}\cdot\frac{1}{n}-\frac{4}{4}\cdot\frac{1}{n^2}+\frac{5}{6}\frac{1}{n^3}-\cdots\right)\equiv n\exp[\psi(n)].$$

It is now easy to prove that, if $n\geqq 2$ (corresponding to $x\geqq\frac{3}{2}$), then

$$n\exp(\psi(n))<n+\frac{3}{2}+\frac{3}{2n}\cdot\qquad\text{and}\qquad n\Phi(n)>n+\frac{1}{2}-\frac{1}{12n}\cdot$$

Now, use the well-known inequalities $\log(n+1)<s(n)<1+\log(n)$, which imply $\exp(x-1)-1<n=n(x)<\exp(x)-1$, to obtain the final result.

Determinants in a Matrix over $GF(p)$

5358 [1966, 89]. *Proposed by H. F. Mattson and E. F. Assmus, Jr. Sylvania Electronic Systems, Waltham, Mass.*

Let A be an $m\times n$ matrix over the integers with $2<m+1<n$. Prove that if

p is a prime such that $p<\max(m, n-m)$ then p divides one of the $m\times m$ determinants in A.

I. *Solution by Robert Breusch, Amherst College.* We reduce all the entries mod p. Multiplication of a whole row by a number $a\not\equiv 0 \pmod{p}$ will not change the determinants' divisibility or non-divisibility by p, nor will any of the legitimate row operations. Moreover we allow $p\leqq\max(m, n-m)$.

Now consider the matrix formed by the first m columns. Either its determinant is $\equiv 0 \pmod{p}$, in which case there is nothing more to prove; or it is possible, by a combination of the previously mentioned operations, to bring this matrix into the form of the identity matrix (mod p), so that the whole matrix A has the form

$$\begin{Vmatrix} 1 & 0 & \cdots & 0 & a_{1,m+1} & \cdots & a_{1,n} \\ 0 & 1 & \cdots & 0 & a_{2,m+1} & \cdots & a_{2,n} \\ \cdot & \cdot & \cdots & \cdot & \cdot & \cdots & \cdot \\ 0 & 0 & \cdots & 1 & a_{m,m+1} & \cdots & a_{m,n} \end{Vmatrix}.$$

The matrix has at least two rows, and has at least two columns beyond the mth.

(1) Let $p\leqq n-m$. Consider three cases:

(a) $a_{1,r}\equiv 0 \pmod{p}$ for some $r(m+1\leqq r\leqq n)$. Then columns 2, 3, $\cdots$, m, r form a matrix whose determinant is divisible by p.

(b) $a_{2,r}\equiv 0 \pmod{p}$ for some r with $m+1\leqq r\leqq n$; then the determinant of the matrix formed by columns 1, 3, $\cdots$, m, r is divisible by p.

(c) All the $a_{1,r}$ and $a_{2,r}$ are $\not\equiv 0 \pmod{p}$, for $m+1\leqq r\leqq n$. Then (mod p), each of the ratios $a_{1,r}/a_{2,r}$ is one of the numbers 1, 2, $\cdots$, $p-1$; and since there are at least p of these ratios, two of them must be equal to each other, say, for $r=s$ and $r=t$ $(s<t)$. Then the determinant of the matrix formed by columns 3, $\cdots$, m, s, t is $\equiv 0 \pmod{p}$.

(2) If $p\leqq m$, then we work with columns number $m+1$ and $m+2$, and reasoning completely analogous to that of (1) shows again that one of the $m\times m$ matrices must have a determinant which is divisible by p.

II. *Solution by Robert Silverman, Ohio State University.* A stronger result may be proved: Let $L(q, n, m)$ denote a set of q^m ordered n-tuples on q objects, such that no two of the n-tuples agree in as many as m components. Such combinatorial configurations may be viewed as systems of $n-m$ m-dimensional orthogonal latin squares on q letters. They have been studied in [1] where it is proved that for $m\geqq 2$, $q>m$ is implied by $q>n-m$ and $n>m+1$.

Let q be a prime power and consider an $m\times n$ matrix A over $GF(q)$, such that every set of m columns is linearly independent. The row space of A forms an $L(q, n, m)$ configuration, and the result of the problem now follows immediately.

1. Robert Silverman, A metrization for power-sets with application to combinatorial analysis, Canad. J. Math., 12 (1960) 158–176.

For another viewpoint on this problem see also:

2. Carl Maneri and Robert Silverman, A vector-space packing problem, J. of Algebra, to appear.

Also solved by L. Carlitz, M. G. Greening (Australia), and the proposers.

Some Dirichlet Multiplications

5360 [1966, 205]. *Proposed by R. B. Eggleston, Avondale College, Australia*

If μ is the Möbius function, evaluate:

$$S(a) = \sum_{d|a} \mu(d)\mu(a/d) \qquad \text{and} \qquad S^*(a) = \sum_{d|a} \sum_{m|d} \mu(m)\mu(d/m).$$

Solution by H. S. Zuckerman, University of Washington. The problem is the special case $k=2$ of the following

THEOREM. *Let*

$$S_k(n) = \sum_{a_1 \cdots a_k = n} \mu(a_1)\mu(a_2) \cdots \mu(a_k), \qquad S_k^*(n) = \sum_{d|n} S_k(d).$$

Then

$$S_k(n) = \prod_{p^e \| n} (-1)^e \binom{k}{e} \qquad \text{and} \qquad S_k^*(n) = S_{k-1}(n).$$

Proof. It is clear that $S_k(n)$ is multiplicative. The summands in $S_k(p^e)$ are zero unless each a_i is 1 or p, in which case the summands are all $(-1)^e$. There are $\binom{k}{e}$ of these nonzero summands. This proves the first formula. We have also

$$\begin{aligned} S_k(n) &= \sum_{a_1 \cdots a_k = n} \mu(a_1) \cdots \mu(a_{k-1})\mu(n/a_1 \cdots a_{k-1}) \\ &= \sum_{d|n} \sum_{a_1 \cdots a_{k-1} = d} \mu(a_1) \cdots \mu(a_{k-1})\mu(n/d) \\ &= \sum_{d|n} S_{k-1}(d)\mu(n/d). \end{aligned}$$

Applying Möbius' inversion theorem we get $S_{k-1}(n) = \sum_{d|n} S_k(d) = S_k^*(n)$. Note that, in particular, we have $S_1(n) = \mu(n)$,

$$S_2(n) = \begin{cases} 0 & \text{if } n \text{ is not cube-free} \\ (-2)^r & \text{if } n = p_1 p_2 \cdots p_r p_{r+1}^2 p_{r+2}^2 \cdots p_{r+t}^2. \end{cases}$$

Also solved by Anders Bager (Denmark), Gabriel Bastien, Robert Breusch, C. C. Cadogan (West Indies), M. S. Demos, E. P. Emerson, J. D. Featherstone, Addison Fischer, F. Göbel (Netherlands), M. G. Greening (Australia), Emil Grosswald, E. C. Hook, F. T. Howard, N. Johnston & E. M. Horadam (Australia), Betty Kvarda, E. S. Langford & D. H. Wagner, R. L.

McFarland, Lieselotte Miller, C. B. A. Peck, Stanton Philipp, H. E. Reinhardt, M. S. Sarma (India), Margaret B. Seay, R. Sivaramakrishnan (India), David A. Smith, Al Somayajulu, Stephen Spindler, Sidney Spital, N. M. Stephens (England), M. V. Subbarao, M. L. Tepley, E. W. Trost (Switzerland), A. M. Vaidya (India), C. S. Venkataraman (India), C. S. Venkataraman & R. Sivaramakrishnan, Dieter Wolke (Germany), and the proposer.

Fischer achieves the above generalization by setting $\mu_1 = \mu$ and iterating

$$\mu_{m+1}^{(n)} = \sum_{d|n} \mu(d)\mu_m(n/d), \qquad \mu_m(n) = \sum_{d|n} \mu_{m+1}(d),$$

noting that μ_k is identical to S_k.

Smith notes that the calculation of $S(a)$ ($\equiv S_2$) may be found in Cashwell and Everett, *The ring of number-theoretic functions*, Pacific J. Math., 9 (1959) 979.

Derivative of Even Polynomials

5361 [1966, 205]. *Proposed by W. E. Sewell, Duke University*

Let $P_n(z)$ be a polynomial of degree n in $z = re^{i\theta}$ with only even powers of z, and let $|P_n(z)| \leqq M$ for z on the curve C whose polar equation is $r = |\cos \frac{1}{2}\theta|$. Show that, for z on C, $|P_n'(z)| \leqq 3Mn$.

Solution by R. K. Meany, Iowa State University. Let $P_n(z) = \sum_{k=0}^{n} c_k z^k$. If $z = re^{i\theta}$, $r = |\cos \frac{1}{2}\theta| = [(1+\cos\theta)/2]^{1/2}$, and $P_n(z)$ contains only even powers of z, then, on C, $P_n(z)$ becomes a trigonometric polynomial in θ of order $3n/2$, say $Q(\theta)$, and

$$Q'(\theta) = \sum_{k=0}^{n} c_k \left(kr^{k-1}e^{ki\theta}\frac{dr}{d\theta} + kir^k e^{ki\theta} \right) = \left(\frac{dr}{d\theta} + ir \right) e^{i\theta} P_n'(z).$$

Now, $\min|dr/d\theta + ir| = \min[\frac{1}{4}\sin^2\frac{1}{2}\theta + \cos^2\frac{1}{2}\theta]^{1/2} = \frac{1}{2}$, and from Bernstein's inequality (see e.g., S. N. Bernstein, *Leçons sur les propriétés extrémales et la meilleur approximations*, Paris, 1926),

$$\max |Q'(\theta)| \leqq (3n/2) \max |Q(\theta)| \leqq 3nM/2.$$

Hence $|P_n'(z)| = |Q'(\theta)| / |dr/d\theta + ir| \leqq 3nM$.

Also solved by I. N. Baker (England), and the proposer.

On Lexicographic Ordering in an Orthonormal Basis

5362 [1966, 205]. *Proposed by John de Pillis, San Francisco State College*

Let $\mathfrak{X}$ be the n-dimensional vector space of n-tuples with complex entries. Suppose $n = p \cdot q$ for some integers p and q. The elements X of $\mathfrak{X}$ can then be represented by the n-tuple

$$X = (x_{11}, x_{12}, x_{13}, \cdots, x_{1q}, x_{21}, x_{22}, \cdots, x_{2q}, \cdots, x_{p1}, \cdots, x_{pq}).$$

The ordering is lexicographic by subscripts. If every $X \in \mathfrak{X}$ is identified with its $p \times q$ matrix (the ijth entry $= x_{ij}$) then for any orthonormal basis $\{X^1, X^2 \cdots, X^n\}$ of $\mathfrak{X}$, show that $\sum_{i=1}^{n} X^i X^{i*} = q \cdot I_p$, where I_p is the $p \times p$ identity matrix and X^{i*} is the adjoint (conjugate transpose) of X^i.

Solution by Walter Noll, Carnegie Institute of Technology. Let $\{Y^1, \cdots, Y^n\}$ be the set of $p \times q$ matrices whose entries are 0 except for a single 1. It is easily verified that this set is identified with an orthonormal basis of $\mathfrak{X}$ and that

$$(*) \qquad \sum_i Y^i Y^{i*} = qI_p.$$

If $\{X^1, \cdots, X^n\}$ is an arbitrarily orthonormal basis of $\mathfrak{X}$ then there exists a $n \times n$ unitary matrix $\|u_{ij}\|$ such that

$$X^i = \sum_j u_{ij} Y^j, \qquad X^{i*} = \sum_k \bar{u}_{ik} Y^{k*}.$$

We find that

$$\sum_i X^i X^{i*} = \sum_{j,k} Y^j Y^{k*} \left(\sum_i u_{ij} \bar{u}_{ik} \right) = \sum_j Y^j Y^{j*},$$

which, together with (*), yields the desired result.

Also solved by M. G. Greening (Australia), A. S. Householder, D. G. Kabe, Marvin Marcus, J. T. Rosenbaum, and the proposer.

Unitary Operators on a Hilbert Space

5363 [1966, 205]. *Proposed by Joseph Kitchen, Duke University*

Let S be an isometry of a Hilbert space H into itself. Prove that there exists a closed subspace M and a unitary operator U on H such that (a) M^0 (the orthogonal complement of M) lies in the range of S, (b) U acts like S on M, and (c) U acts like S^{-1} on M^0.

Solution by T. Kriete, University of Virginia. Denote the range of S by R, and assume R a proper subspace of H. S^{-1} makes sense on R since if $y \in R$, $y = Sx$ for at least one $x \in H$, and if $Sx_1 = Sx_2$, $\|S(x_1 - x_2)\| = \|x_1 - x_2\| = 0$, so there is only one such x.

A theorem of P. R. Halmos (*Shifts on Hilbert Spaces*, Jour. Reine Angew. Math., 208 (1961) pp. 102 ff.) states that H may be written as the orthogonal direct sum

$$H = N \oplus R^\perp \oplus SR^\perp \oplus S^2R^\perp \oplus S^3R^\perp \oplus \cdots,$$

where S restricted to N is unitary. The solution follows easily from this representation. Let

$$M = R^\perp \oplus S^2R^\perp \oplus S^4R^\perp \oplus \cdots \text{ and } P = SR^\perp \oplus S^3R^\perp \oplus S^5R^\perp \oplus \cdots = SM.$$

Then S^{-1} makes sense on P and $S^{-1}P = M$. Let $M^0 = P \oplus N$. Clearly $H = M \oplus M^0 = M \oplus N \oplus P$. If $f \in H$, write $f = m + n + p$ where $m \in M$, $n \in N$, $p \in P$. Since S is isometric, all of the subspaces which have appeared are closed. Now

$$Uf = Um + Un + Up = Sm + S^{-1}n + S^{-1}p$$

is the described unitary operator.

Also solved by M. D. Mavinkurve, J. T. Rosenbaum, and the proposer.

Collinear Arrays of Lattice Points $\leqq x^a$

5364 [1966, 205]. *Proposed by Erwin Just and Norman Schaumberger, Bronx Community College*

Let $f(x)$ be an integral valued function defined for all positive integers with $0 \leqq f(x) \leqq x^a$, $0 < a < 1$. (a) Prove that the graph of $f(x)$ contains at least k collinear points for any positive integer k. (b) Is the same conclusion true when $0 \leqq f(x) \leqq x$?

Partial Solution by Dan Marcus, Adelphi University. With $0 < a < 1$ we may show that the graph of $f(x)$ contains, for each k, a horizontal configuration of k points. For suppose to the contrary that each horizontal line contains at most $k-1$ points. Then the number of points of $y=f(x)$ in the region bounded by $y=0$, $y=x^a$, $x=T$ does not exceed $(k-1)(T^a+1)$. But the number of points of the graph in this region must be at least T—a contradiction for sufficiently large T.

Also solved (part (a)) by the proposers. No solution for part (b) was received.

Nonsingular Decompositions of the Identity Matrix

5365 [1966, 205]. *Proposed by A. Himmelfarb, Fordham University*

Let R be a ring with identity and n a natural number greater than 1. Show that there exist two nonsingular matrices whose sum is the identity matrix.

I. *Solution by J. L. Brenner, Stanford Research Institute.* The case n even is taken care of by the decomposition

$$\begin{bmatrix} 1 & -1 \\ 1 & 0 \end{bmatrix} + \begin{bmatrix} 0 & 1 \\ -1 & 1 \end{bmatrix},$$

and the case $n>1$ odd by the additional decomposition

$$\begin{bmatrix} 1 & -1 & 0 \\ 1 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix} + \begin{bmatrix} 0 & 1 & 0 \\ -1 & 1 & 1 \\ 0 & -1 & 1 \end{bmatrix}.$$

A solution for any $n>1$ is obtained as the direct sum of matrices of these types.

II. *Solution by M. D. Mavinkurve, Siddharth College, India.* Let $A=(a_{ij})$ be the $n \times n$ matrix with $a_{i,i+1}=1$ for $i=1, \cdots, n-1$, $a_{11}=a_{n1}=1$ and $a_{ij}=0$ otherwise. $B=I-A$. These are nonsingular as may be seen by shifting rows.

Also solved by G. A. Heuer, E. S. Langford & D. H. Wagner, Azriel Rosenfeld, W. R. Scott, and the proposer.

Differentiable Functions with Prescribed Discontinuities

5366 [1966, 206]. *Proposed by H. D. Keesing, University of Wisconsin*

Find an explicit function f on $[0, 1]$ to the real numbers, such that f' is defined on $[0, 1]$ and discontinuous on the rationals in $[0, 1]$.

Solution by L. A. Steen, St. Olaf College. Let $f(x)=x^2 \sin(1/x)$; then f is differentiable everywhere, and f' is discontinuous only at $x=0$. Let $r_1, r_2, \cdots$ be an enumeration of the rationals in $[0, 1]$; define

$$g(x) = \sum_{n=1}^{\infty} 2^{-n} f(x - r_n).$$

Then $g'(x)=\sum_{n=1}^{\infty} 2^{-n} f'(x-r_n)$, since both series are uniformly convergent. Then g' exists and is discontinuous at each rational in $[0, 1]$.

Also solved by Daniel Asimov, Robert Breusch, D. A. Hejhal, H. D. Keesing, E. S. Langford, Jaroslav Lukeš (Czechoslovakia), Dan Marcus, R. E. Moyer, and Michael Schulz.

A variety of problems of this sort have been treated in the literature. For an excellent summary see the paper by A. M. Bruckner and J. L. Leonard on Derivatives in no. 11 of the Slaught Memorial Papers, *Papers in Analysis*, 73 (1966) No. 4, Pt. II, this MONTHLY. Specifically compare the paper by Hailperin referred to on p. 27.

Max Jeger, Transformation Geometry. English version by A. W. Deicke and A. G. Howson. Wiley, New York, 1966. $3.50 (paperback).

The book contains the essentials of the geometry course which the author regularly gives to his classes at the Oberrealschule (a high level science high-school) at Lucerne, Switzerland. The translation has been done very competently.

In the opinion of the reviewer, a group theoretical treatment of elementary geometry based on the Euclidean groups and affine transformations gives the students a much better insight into the working of both geometry and group theory than the usual foundations course based on projective geometry. The present booklet is by far the best available treatment of this kind for a one-quarter course in Euclidean geometry for students with a minimum of preparation. It is really teachable, in contrast to I. M. Yaglom's Geometric Transformations. It deals with the fundamentals of group theoretic geometry in a sound way. It has many interesting problems, though not enough homework problems by American standards.

On this occasion, the reviewer wants to issue a plea to the publishers of reprints and translations for a new issue, preferably in English translation, of the grandfather of all books on Euclidean transformation geometry, Hadamard's *Géometrie plane.* While that book is pre-Hilbert and therefore completely outdated from the axiomatic point of view, it still can serve as a source of much inspiration in group theoretical thinking and in geometrical problems. Any teacher wanting to supplement the problems in Jeger's book will find an ample supply in Hadamard. Many problems treated in both Yaglom and Jeger can in fact be traced back to Hadamard. Hadamard's example also shows that you can become a famous analyst by teaching geometry.

H. GUGGENHEIMER, University of Minnesota

Functions of a Complex Variable: Theory and Technique. By George F. Carrier, Max Krook, Carl E. Pearson. McGraw-Hill, New York, 1966. ix+438 pp. $10.50.

This book, in spite of its title, is primarily concerned with topics of the technique and application of complex variable theory. It treats conformal mapping, contour integration, some special functions (gamma, hypergeometric, Legendre, and Bessel functions), asymptotic expansions, and transform methods. The final chapter deals with the Wiener-Hopf method and with related material on integral equations. The authors provide many illustrative examples and a well-selected collection of interesting problems. The student who works a substantial number of these will have a good grasp of *applied* function theory. But he will need an experienced mentor! For the *theory* is not treated so effectively. The hints for the problems and those parts of the explanations that are "readily seen," are, by no means, always on the surface.

The methods here exposed will be understandable to the user only if he has had previous acquaintance with the underlying justifications, or if his study is directed by someone in a position to clarify and to tighten a good number of the arguments. But the reader with an introductory course in function theory behind him will find here a large variety of uses of this theory. They are explained lucidly, and there are, in most cases, some allusions to the conditions under which the various techniques are applicable.

This work is in no sense a handbook of special tricks; it is a serious text for a substantial year course in the topics that it treats.

E. C. SCHLESINGER, Connecticut College

Integral Transforms and Operational Calculus. By V. A. Ditkin and A. P. Prudnikov. Translated by D. E. Brown, translation edited by I. N. Sneddon. Pergamon Press, Oxford, 1965. (International series of Monographs in Pure and Applied Mathematics, Volume 78.) xii+526 pp. $15.50.

This book contains mountains of information but no proofs. Weighted more than two-to-one in favor of "tables" over "theory," the work touches on Fourier, Laplace, Mellin, Hankel, Meijer, Kontorovitch-Lebedev, Mehler-Fock, and Hilbert transforms. The Laplace transform receives, along with a table of over four hundred entries, a somewhat fuller theoretical treatment, including discussions of the inversion problem and of several applications. The "operational calculus" in the title refers to a chapter on Mikusinskii's theory. One innovation is the authors' replacement of the usual convolution by its derivative; this device makes convolution with a constant function coincide with ordinary multiplication by the constant. The chapter concludes with a brief but valuable sketch of an analogous calculus for the operator $d/dt(t(d/dt))$, in which the role of the Laplace transform is played by a certain Bessel transform.

The reader looking for a rigorous development of integral transform theory will find little here other than references to the bibliography; it is a book for those who wish to write down solutions. A beginner would find the exposition rather terse, and had better go into the tables armed with a stout heart and a copy of Whittaker and Watson. An expert might value the book as a compendious reference.

R. C. RIDDELL, University of British Columbia

Vector Analysis. By Barry Spain. Van Nostrand, London, 1965. 114 pages. $5.85.

This book contains a development of vector calculus, assuming familiarity with the calculus of real-valued functions of two and three variables. Coordinate-free definitions are given and, where there are proofs, they are coordinate-free. The book is not intended as a first introduction to the subject. The author assumes that the topics are motivated by previous acquaintance from, for example, a physics course. This reviewer concludes that the book intends to provide a mathematical foundation for the techniques of vector calculus. If this is the aim, then the book is unsuccessful. Definitions and theorems are not clearly stated. There has been an apparently arbitrary choice of what is proved and what is left unproved and many "proofs" are simply unjustified manipulations with the magic notation of Leibniz. There are some serious errors. For example, on page 33 the author concludes that a vector-valued function of one real variable is equal to its Taylor series if one only assumes that (for some n) the $(n+1)$st derivative is continuous. On page 62, an example is presented to show that curl $\mathbf{a}=0$ on a multiply-connected region does not imply that the line integral is independent of the path. This example is fallacious and, moreover, the calculation given to support it (a blindly performed change of variable in an integral) should cause the reader to question many other "proofs" which hinge on similar calculations.

H. E. CHRESTENSON, Reed College

NEWS AND NOTICES

EDITED BY RAOUL HAILPERN, SUNY at Buffalo

Readers are invited to contribute to the general interest of this department by sending news items to Raoul Hailpern, Mathematical Association of America, SUNY at Buffalo (University of Buffalo), Buffalo, New York 14214. Items must be submitted at least two months before publication can take place.

PERSONAL ITEMS

University of California, Berkeley: Professor L. A. Henkin has accepted the position of Acting Chairman of the Department of Mathematics; Associate Professor R. S. Lehman has been promoted to Professor and has accepted the position of Vice Chairman of the Department of Mathematics; Professors J. L. Kelley and P. E. Thomas have been appointed Research Professors in the Miller Institute for Basic Research, Berkeley; Dr. David Gale, Brown University, has been appointed Professor of Industrial Engineering and Mathematics; Associate Professor Hewitt Kenyon, George Washington University, has been appointed Visiting Associate Professor; Associate Professor L. E. Dubins has been promoted to Professor.

Central Missouri State College: Mr. C. H. Best and Mr. L. S. Dilley have been promoted to Assistant Professors.

Harvey Mudd College: Associate Professor C. S. Coleman has been promoted to Professor; Assistant Professors A. F. Pixley and A. M. White have been promoted to Associate Professors.

Louisiana State University in New Orleans: Assistant Professor M. P. Berri, Tulane University, has been appointed Visiting Associate Professor; Associate Professor Diran Sarafyan has been promoted to Professor; Dr. Jeong Sheng Yang, University of Miami, has been appointed Assistant Professor.

State University of New York at Buffalo: Assistant Professor G. R. Blakley, University of Illinois, has been appointed Associate Professor; Assistant Professor K. D. Magill, Jr., has been promoted to Associate Professor.

Dr. R. A. Alo, Pennsylvania State University, has been appointed Assistant Professor at Carnegie Institute of Technology.

Associate Professor J. A. Ferling, Claremont Men's College, has been promoted to Professor.

Dr. C. H. Franke, Bell Telephone Laboratory, Whippany, has been appointed Assistant Professor at Seton Hall University.

Assistant Professor T. K. Frutiger, Lycoming College, has been appointed Assistant Professor at Colgate University.

Associate Professor R. F. Gabriel, Seton Hall University, has been promoted to Professor.

Dr. R. W. Goodman, Massachusetts Institute of Technology, has been promoted to Assistant Professor.

Dr. W. E. Gould, Washington College, has been appointed Associate Professor at Bradley University.

Associate Professor Arnold Grudin, Denison University, has been promoted to Professor.

Associate Professor Melvin Hausner, New York University, has been promoted to Professor.

Assistant Professor R. C. N. Hourston, Knox College, has been promoted to Associate Professor.

Associate Professor R. B. Jackson, Jr., Davidson College, has been promoted to Professor.

Assistant Professor W. A. Kirby, Bowling Green State University, has been promoted to Associate Professor.

Assistant Professor J. A. Lutts, Loyola College, has been appointed Assistant Professor at the University of Massachusetts at Boston.

Assistant Professor E. M. Mandelbaum, West Chester State College, has been promoted to Associate Professor.

Mr. W. E. Mastrocola, Colgate University, has been promoted to Assistant Professor.

Assistant Professor R. F. McCoart, Jr., Georgetown University, has been appointed Associate Professor at Loyola College.

Mr. Stephen Milles, State University of New York at Buffalo, has been appointed Assistant Professor at Canisius College.

Mrs. Dixie Moore, Morehead State University, has been promoted to Assistant Professor.

Mr. J. G. Moser, Daniel Wagner Associates, has been appointed Associate Professor at West Chester State College.

Mrs. Janet K. Myhre, Claremont Men's College, has been promoted to Assistant Professor.

Professor F. D. Parker, SUNY at Buffalo, has been appointed Professor at the St. Lawrence University.

Dr. R. J. Plemmons, National Security Agency, has been appointed Associate Professor at the University of Mississippi.

Professor G. E. Reves has been appointed Head of the Mathematics Department at The Citadel.

Associate Professor R. A. Roberts, Denison University, has been promoted to Professor.

Assistant Professor J. I. Rosenthal, Nassau Community College, has been appointed Assistant Professor at Saint Peter's College.

Mr. R. D. Salmon, Louisiana Polytechnic Institute, has been promoted to Assistant Professor.

Assistant Professor C. S. Smith, Lake Forest College, has been promoted to Associate Professor.

Associate Professor R. A. Stokes, University of Mississippi, has been promoted to Professor.

Associate Professor W. A. Thompson, Jr., Florida State University, has been promoted to Professor and appointed Acting Head of the Mathematics Department.

Mr. Robert Vivona, Fordham University, has been appointed Assistant Professor at Marist College.

Dr. L. H. Williams, Florida State University, has been appointed Associate Professor and Director of the Computer Center at Auburn University.

Assistant Professor P. R. Young, Stanford University, has been appointed Assistant Professor at Purdue University.

Professor Emeritus P. A. Caris, University of Pennsylvania, died on July 5, 1966. He was a member of the Association for forty-three years.

Professor Bernard Friedman, University of California, Berkeley, died on September 12, 1966. He was a member of the Association for six years.

Lt. Col. C. A. Rupp, Defense Department, Washington, D.C., died in October, 1966. He was a member of the Association for forty-three years.

Associate Professor J. E. Vollmer, Western Michigan University, died on July 7, 1966. He was a member of the Association for seventeen years.

MATHEMATICAL ASSOCIATION OF AMERICA

Official Reports and Communications

MAY MEETING OF THE ROCKY MOUNTAIN SECTION

The forty-ninth annual meeting of the Rocky Mountain Section of the MAA was held at Colorado State University, Fort Collins, Colorado, on Friday and Saturday, May 13 and 14, 1966.

There were 122 people registered for the meeting, including Dean W. E. Briggs, Sectional Governor and Professor F. M. Stein, Section Chairman.

An invited address, "Algebraic Topology for Undergraduates(?)" was given on Friday afternoon by Professor A. B. Willcox, Amherst College, Second Vice-President of the Mathematical Association of America. On Saturday morning Professor George Seifert of Iowa State University delivered the SIAM invited address. His title was "Almost Periodic Solutions for Nonautonomous Systems of Ordinary Differential Equations."

At the banquet Friday night Professor M. L. Madison of Colorado State University presided. The Section was welcomed by President W. E. Morgan of Colorado State University. Following the banquet mathematical films were shown and card tables were available.

The business meeting was held on Saturday morning, at 8:45 A.M., with Professor Stein presiding.

Professor R. E. Doutt reported for the Meeting Committee that the 1967 meetings would be held at Western State College in Gunnison, Colorado. He announced that the University of Denver had extended an invitation to meet there in 1968. It was moved, seconded and carried that this invitation be accepted.

It was announced that a letter had been received from Southern Colorado State College at Pueblo requesting that that institution be listed on the rotation list for future meetings. The motion was made, seconded and carried that Southern Colorado State be added to the list of those institutions in District D.

The following officers were elected for 1966–67: Chairman, W. E. Dorgan, Western State College; Vice-Chairman, Kenneth Noble, University of Denver; and Secretary-Treasurer, W. N. Smith, University of Wyoming.

The chairman announced the appointment of Professor R. L. Eisenman of the Air Force Academy, and Professor Neville Hunsaker of Utah State University, to serve on the Meeting and Nomination Committees, respectively. These standing committees are now:

Meeting Committee: R. E. Doutt, South Dakota School of Mines; Chairman: R. W. Ellingwood, University of Colorado; R. L. Eisenman, Air Force Academy.

Nomination Committee: F. N. Fisch, Colorado State College; Chairman: W. E. Dorgan, Western State College; Neville Hunsaker, Utah State University.

Professor E. R. Deal of Colorado State University, Contest Chairman for the Annual High School Mathematics Contest, reported that 140 schools had participated—18 from Wyoming, 24 from Utah and 98 from Colorado.

The following 17 papers were presented at the meeting:

1. *Hilbert space with an indefinite inner product*, by R. W. McKelvey, University of Colorado.

An indefinite inner product $[x, y]$ on a vector space V is a symmetric bilinear functional such that $[x, x]$ may be positive, negative or zero. A Nevanlinna space is a Hilbert space with positive definite inner product (x, y) and a second indefinite inner product given by $[x, y]=(Jx, y)$ where J and J^{-1} are bounded self-adjoint operators. The talk is a brief exposition of the theory of Nevanlinna space: subspaces, orthogonal projectors, Cartesian sum decompositions, and the spectral resolution for a self-adjoint operator.

2. *The generalized Jordan canonical form*, by D. W. Robinson, Brigham Young University.

One of the topics usually considered in a course in linear algebra is the study of various matrix representations for a linear transformation on a vector space over a field. If the field is algebraically closed, then the most useful and well-known representation is the Jordan canonical form. However, it is not as well known that, by means of a slight extension, this form may essentially be used over a much larger class of fields. The purpose of this paper is to suggest a way to bring this "generalized Jordan canonical form" into the classroom.

3. *Approximate continuity*, by J. E. Kimber, Jr., Utah State University.

4. *Trilinear equations in a finite field*, by A. Duane Porter, University of Wyoming.

Let $F=GF(q)$ be the finite field of $q=p^r$ elements, p arbitrary, and let $N(n_1a)$ denote the number of solutions in F of $a_1x_1y_1z_1+\cdots+a_nx_ny_nz_n=a$. Also, let $N(n, a_i, b_i, a, b)$ denote the number of solutions in F of the system $a_1x_1y_1z_1+\cdots+a_nx_ny_nz_n=a$, $b_1x_1y_1z_1+\cdots+b_nx_ny_nz_n=b$, where all coefficients are from F. Explicit formulas for both $N(n, a)$ and $N(n, a_i, b_i, a, b)$ are obtained. To evaluate $N(n, a_i, b_i, a, b)$, two cases are considered. First, when $a_i, b_i\neq 0$, $1\leqq i\leqq n$, a, b arbitrary, and second, when a_i, b_i are all arbitrary.

5. *On Ramanujan's sum*, by G. S. Donovan, University of Colorado.

6. *Compound stochastic processes*, by S. A. Patil and M. M. Siddiqui, Colorado State University.

7. *A simple remark on Waring-type problems and linear Diophantine equations*, by A. J. Kempner, University of Colorado.

"Obvious, but not trivial": $1x_1+2x_2+3x_3+\cdots+kx_k+\cdots=n$, $n, x_1, x_2, x_3, \cdots$ integers $\geqq 0$, has for all n solutions $3\geqq x_1\geqq x_2\geqq x_3\geqq\cdots$ (0 from same point on). Similarly $1x_1+3x_2+5x_3+\cdots+(2k-1)x_k+\cdots=n$ has for all n solutions $4\geqq x_1\geqq x_2\geqq x_3\geqq\cdots$ (0 from same point on). Corresponding statements are given for Waring's general theorem, for Fermat's $x^n+y^n=F^n$, etc.

8. *A problem on integral operators*, by G. H. Meisters, University of Colorado.

Because everywhere-defined linear transformations of Hilbert space are bounded whenever they (1) are closed, (2) have adjoints with dense domains, (3) have a matrix representation—and for other reasons, the author conjectures first (vaguely) that linear transformations which are "constructively" defined everywhere on Hilbert space (or any B-space) are necessarily bounded, and second (precisely) that everywhere-defined (absolutely convergent Lebesgue) integral operators on Hilbert space are necessarily bounded. The author proves that if there exists a measurable set $E_1\subset E(=\text{measurable }\subset R^n)$ such that $m(E-E_1)=0$ and that for all $x\in E_1$ and all $f\in L_2(E)$, $Kf(x)=\int_E k(x, y)f(y)dy$ exists and belongs to $L_2(E)$, where k is measurable, then $K:L_2(E)\to L_2(E)$ is bounded.

9. *Differential inequalities with exceptional sets*, by J. W. Bebernes and G. H. Meisters, University of Colorado.

The following two theorems are slightly generalized versions of results of G. H. Meisters and this author. THEOREM 1: If $D_+u(t)\leqq f(t, u(t))$ a.e., and $D_+u(t)<+\infty$ nearly everywhere on $[a, b]$ (n.e. allows a countable exceptional set) where u and f are continuous, then any maximal solution ϕ_m of $x'=f(t, x)$ with $\phi_m(a)\geqq u(a)$ satisfies $u(t)\leqq\phi_m(t)$ on its interval of existence. THEOREM 2: Suppose there is a nonnegative continuous function $h(t, u)$ such that $u'=h(t, u)$, $u(t_0)=0$, has zero as its unique (right) solution and that $x_1\leqq x_2$ implies $f(t, x_2)-f(t, x_1)\leqq h(t, x_2-x_1)$ a.e. on $[a, b]$. If $D^+u(t)<+\infty$, $D^+v(t)>-\infty$ n.e., and if $D^+u(t)-f(t, u(t))\leqq D^+v(t)-f(t, v(t))$ a.e., for continuous u and v with $u(a)\leqq v(a)$, then $u(t)\leqq v(t)$ on $[a, b]$.

10. *The approximate solution of Riccati's equation*, by Ronald Huffstutler and F. M. Stein, Colorado State University.

This paper discusses the approximate solution of the Riccati equation $L(y)\equiv y'-P(x)y-Q(x)y^2=R(x)$ over $[0, 1]$ by a sum of zero-th order Bessel functions $S_n(x)=\sum_{m=1}^{n}B_mJ_0(\lambda_m x)$,

satisfying $y_0=y(x_0)$, that is the *best approximation* in the sense that $\int_0^1|R(x)-L[S_n(x)]|^m dx$, $m>0$, is a minimum. Particular use is made of the fact that $J_0'(x)=-J_1(x)$, and thus both the solution $y(x)$ and its derivative $y'(x)$ can be uniformily approximated by $S_n(x)$ and $S_n'(x)$ respectively throughout $[0, 1]$.

11. *On triples of quasi-conjugate matrices*, by L. S. Johnson and V. J. Varineau, University of Wyoming.

The concept of quasi-conjugate n-tuples of matrices is re-examined and some of its most interesting properties are discussed. A similarity relation for quasi-conjugate n-tuples is defined. The set of quasi-conjugate triples over a finite field is examined with respect to the similarity partition and the number of triples in each class is determined. The number of similarity classes for a finite field with m elements is found to be m.

12. *Geometry and vision: A plea for perspective geometry in senior high school*, by A. J. Kempner, University of Colorado.

Few of our students realize that we live our daily lives in two mutually contradictory worlds of geometry: the tactile (Euclidean) and the optical (perspective). An understanding of this situation—apparently totally lacking under our present high-school training—would be of marked scientific, cultural and philosophical value. To mention only one aspect: it would prepare the ground for psychological acceptance of the various non-Euclidean geometries and of the Einstein-Minkowski geometry of relativity, etc. A course including a satisfactory foundation of projective geometry could well be fitted into our present high school set-up.

13. *The statistics program at Colorado State University*, by J. S. Williams, Colorado State University.

14. *Implementation of CUPM Recommendations, Levels I and III*, Panel on Teacher Training, by J. J. Fisher, Colorado State Department of Education.

15. *The junior college mathematics curriculum*, by T. D. Cavanagh, Colorado State College.

The speaker discussed a study he had made of the junior college mathematics curriculum. The study was primarily a questionnaire study. A survey of the catalogues available from the junior colleges in the sample was included as a part of the study. The speaker discussed the present mathematics offerings of the junior colleges, the ways in which these offerings are changing, and the factors which influence such changes. He also made some recommendations for change in the junior college mathematics curriculum.

16. *Use of modern language techniques in the teaching of mathematics*, by Miss Ann Pape, Lakewood, Colorado.

Over a four year period, the audio-lingual methods used in the teaching of languages, including extensive use of tape recorders, have been applied in mathematics classes. Postulates and theorems are taught like grammar drills in a language situation. There are a number of advantages to this method. Necessary repetition is attained with less effort; slow learners and chronic absentees are helped without infringing upon teacher time; novelty and variety are added. The progress of groups using audio-lingual methods shows a significant improvement in accomplishment over control groups.

17. *Information feedback for mathematics student teachers*, by J. M. Moser, University of Colorado.

The paper discussed a study of the mathematics student teaching experience. The study attempted to minimize the subjective nature of evaluations of student teaching through the medium of feeding back objective information to the student teacher by means of audio tape recordings and discussions of teaching behavior matrices which are part of the Minnesota System of Interaction Analysis. Observations made during a year indicated that student teachers tend to become fairly

rigid in the pattern of their teaching behavior once they have found one which suits their personality. The greatest amount of student participation and teacher-student interaction was found in those classes which used SMSG or UICSM text materials.

W. N. SMITH, *Secretary-Treasurer*

CALENDAR OF FUTURE MEETINGS

Forty-eighth Summer Meeting, University of Toronto, Toronto, Ontario, Canada, August 28–30, 1967.

Fifty-first Annual Meeting, San Francisco, California, January 25–27, 1968.

ALLEGHENY MOUNTAIN, West Virginia University, Morgantown, May 6, 1967.

ILLINOIS, University of Illinois, Urbana, May 12–13, 1967.

INDIANA, Wabash College, Crawfordsville, May 13, 1967.

IOWA, Drake University, Des Moines, April 21, 1967.

KANSAS, Fort Hays State College, Hays, April 22, 1967.

KENTUCKY, Murray State University, Murray, April 1, 1967.

LOUISIANA-MISSISSIPPI, Jung Hotel, New Orleans, Louisiana, March 4–5, 1967.

MARYLAND-DISTRICT OF COLUMBIA-VIRGINIA, University of Virginia, Charlottesville, April 22, 1967.

METROPOLITAN NEW YORK, Long Island University, Brooklyn Division, March 18, 1967.

MICHIGAN, University of Michigan, Ann Arbor, March 18, 1967.

MINNESOTA, St. John's University, Collegeville, May 6, 1967.

MISSOURI, Northeast Missouri State Teachers College, Kirksville, April 29, 1967.

NEBRASKA, University of South Dakota, Vermillion, May 6, 1967.

NEW JERSEY

NORTHEASTERN, Mt. Allison University, Sackville, New Brunswick, June 23–24, 1967.

NORTHERN CALIFORNIA

OHIO, Ohio State University, Columbus, April 22, 1967.

OKLAHOMA-ARKANSAS, Northeastern State College, Tahlequah, Oklahoma, April 1–2, 1967.

PACIFIC NORTHWEST, University of Montana, Missoula, June 16–17, 1967.

PHILADELPHIA, University of Delaware, Newark, November 18, 1967.

ROCKY MOUNTAIN, Western State College of Colorado, Gunnison, May 12–13, 1967.

SOUTHEASTERN, Florida Presbyterian College, St. Petersburg, Florida, March 31–April 1, 1967.

SOUTHERN CALIFORNIA, San Diego State College, San Diego, March 11, 1967.

SOUTHWESTERN, University of Arizona, Tucson, March 31–April 1, 1967.

TEXAS, Austin College, Sherman, April 14–15, 1967.

UPPER NEW YORK STATE, State University College, Plattsburgh, May 20, 1967.

WISCONSIN, St. Norbert College, DePere, May 6, 1967.

FUTURE MEETINGS OF OTHER ORGANIZATIONS

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, New York, N. Y., December 26–31, 1967.

AMERICAN MATHEMATICAL SOCIETY, Toronto, Ontario, Canada, Aug. 29–Sept. 1, 1967.

AMERICAN SOCIETY FOR ENGINEERING EDUCATION, Michigan State University, June 19–23, 1967.

ASSOCIATION FOR COMPUTING MACHINERY, Sheraton-Park, Washington, D. C., August 29–31, 1967.

ASSOCIATION FOR SYMBOLIC LOGIC

CENTRAL ASSOCIATION OF SCIENCE AND MATHEMATICS TEACHERS, Chicago, November 23–25, 1967.

INSTITUTE OF MATHEMATICAL STATISTICS

NATIONAL COUNCIL OF TEACHERS OF MATHEMATICS, Convention Center, Las Vegas, Nevada, April 16–20, 1967.

OPERATIONS RESEARCH SOCIETY OF AMERICA, New York Hilton Hotel, May 31–June 2, 1967.

PI MU EPSILON

SOCIETY FOR INDUSTRIAL AND APPLIED MATHEMATICS, Shoreham Hotel, Washington, D. C., June 12–15, 1967 (Symposium on applied probability and fluid dynamics).

Van Nostrand

Publishes the Finest Mathematics Texts

The University Series in Undergraduate Mathematics. Editors: John L. Kelley, University of California, Berkeley; and Paul R. Halmos, University of Michigan.

LINEAR GEOMETRY
by K. W. Gruenberg, Queen Mary College of the University of London, and Alan J. Weir, University of Sussex. Available March, 1967; about 250 pages; approximately $7.50. Recommended for algebraic approaches to linear geometry at the undergraduate level.

A MODERN INTRODUCTION TO GEOMETRIES
by Annita Tuller, Hunter College of the City University of New York. **Just Published.** 312 pages; $7.50. Recommended for the basic undergraduate course.

CALCULUS WITH ANALYTIC GEOMETRY
by Albert Fadell, State University of New York at Buffalo. 1964; 705 pages; $9.75. Recommended for the first year of calculus.

The University Series in Higher Mathematics. Editorial Board: Marshall H. Stone, The University of Chicago; L. Nirenberg, New York University; and S. S. Chern, University of California, Berkeley.

A HILBERT SPACE PROBLEM BOOK
by Paul R. Halmos, The University of Michigan. Available March, 1967; about 340 pages; approximately $11.50.

DENUMERABLE MARKOV CHAINS
by John G. Kemeny and J. Laurie Snell, both of Dartmouth College, and Anthony W. Knapp, Massachusetts Institute of Technology. 1966; 452 pages; $12.50.

VALUE DISTRIBUTION THEORY
by Leo Sario, University of California, Los Angeles, and Kiyoshi Noshiro, Nagoya University. 1966; 256 pages; $7.50.

Van Nostrand (London) Books

LAPLACE TRANSFORM THEORY
by M. G. Smith, Sir John Cass College, London. 1966; 124 pages; $3.75 (paper).

FUNCTIONS OF REAL VARIABLES
by R. Cooper, Queen's University of Belfast. 1966; 228 pages; $4.95 (paper).

Van Nostrand Mathematical Studies Series. General Editors: Paul R. Halmos and Frederick W. Gehring, both of The University of Michigan.

LECTURES ON THE THEORY OF FUNCTIONS OF A COMPLEX VARIABLE 9
by George W. Mackey, Harvard University. Available March, 1967; 274 pages; $3.95 (paper).

LECTURES ON QUASICONFORMAL MAPPINGS 10
by Lars B. Ahlfors, Harvard University. 1966; 146 pages; $2.75 (paper).

SIMPLICIAL OBJECTS IN ALGEBRAIC TOPOLOGY 11
by J. Peter May, Yale University. Available March, 1967; 176 pages; $2.95 (paper).

TOPICS IN THE THEORY OF FUNCTIONS ON ONE COMPLEX VARIABLE 12
by Wolfgang Fuchs, Cornell University, in collaboration with A. Schumitsky. Available March, 1967; 108 pages; $3.25 (paper).

SELECTED PROBLEMS IN EXCEPTIONAL SETS 13
by Lennart Carleson, University of Upsala. Available March, 1967; about 160 pages; approximately $2.95 (paper).

ELEMENTS OF APPROXIMATION THEORY 14
by Leopoldo Nachbin, University of Rochester and Instituto de Matemática Pura e Applicada. Available March, 1967; about 128 pages; approximately $2.75 (paper).

Send for your on-approval copies.

A New Text From Macmillan

First Year Calculus

By Arthur B. Simon, Northwestern University

"I believe," says Professor Simon in the preface, "that each student, whether a math major or not, **deserves the opportunity to be challenged**—not only by applications in the form of exercises but also by the concepts themselves. FIRST YEAR CALCULUS, a modern introduction to the study of single variable calculus, including infinite series and vectors, accomplishes this goal.

The text successfully blends three vital elements to make it especially teachable: **drill,** counterbalanced by **intuition,** and tempered by **rigor.** Thus, individual proofs are developed rigorously and sufficient explanatory material is provided so that students may intuitively grasp the derivation.

Exercises form an integral part of the text. They appear at the end of each section and are graded in difficulty, starred exercises being the most difficult. Review exercises appear throughout the book, and compel the student to review important concepts studied earlier and needed in later lessons. Answers to selected problems are provided at the end of the book.

1967, approx. 400 pages, prob. $9.95

Write to the faculty service desk for an examination copy.

THE MACMILLAN COMPANY

866 Third Avenue, New York, N.Y. 10022

New Texts From Macmillan

Modern Calculus with Analytic Geometry VOLUME I
By Dr. A. W. Goodman, The University of South Florida
Mathematical rigor, clarity, and lively, imaginative language combine to make this new text an exceptionally good introductory book for students in science, mathematics, and engineering. All important theorems are rigorously proved. This volume covers functions of single variables. Volume II will cover functions of several variables.
1967, approx. 832 pages, prob. $10.95

Algebra
By Saunders MacLane, The University of Chicago, and Garrett Birkhoff, Harvard University
Emphasizing the new concepts of category and functor, the authors present a truly modern introductory approach to linear algebra. The starting point is the idea of functions and the composition of functions; in the treatment of set theory this idea leads to the first instances of the general concept of universality. Following these introductory concepts is a discussion of the basic types of algebraic systems.
1967, approx. 672 pages, prob. $11.95

Elements of Abstract Algebra, SECOND EDITION
By John T. Moore
This second edition of a successful text has been almost entirely rewritten. The clarity and sound organization of the original work has been retained, plus much broader, more comprehensive coverage.
1967, approx. 304 pages, prob. $7.95

Boundary Value Problems of Mathematical Physics, VOLUME I
By Ivar Stakgold, Northwestern University
MACMILLAN SERIES IN ADVANCED MATHEMATICS AND THEORETICAL PHYSICS, MARK KAC, EDITOR
This first of a two-volume work examines Green's functions and eigen function expansions. The volume contains much of the modern mathematical material needed in the development of these two points of view.
1967, 000 pages, prob. $12.95

An Introduction to Analysis
By Wilson M. Zaring, University of Illinois
Here is an excellent text for a course in analysis taken by junior and senior undergraduate mathematics majors, especially prospective teachers. The author takes a structural point of view, emphasizing the role of the field postulates and includes a number of proofs and theorems that do not appear in other books at this level.
1967, approx. 352 pages, prob. $8.75

A Survey of Modern Algebra, THIRD EDITION
By Garrett Birkhoff, Harvard University, and Saunders MacLane, The University of Chicago
". . . still probably the best introduction to the subject because it never loses sight of the concrete origins of the abstract ideas or of their applications in other fields, and is clearly written with many examples and exercises."—**Science Books, May, 1966**
1965, 437 pages, $8.50

Topics from the Theory of Numbers
By Emil Grosswald, University of Pennsylvania
Written for advanced undergraduate and graduate courses, this self-contained development of number theory presents many of the topics in number theory appropriate at this level.
1966, 299 pages, $8.50

Introduction to Probability and Statistics, SECOND EDITION
By B. W. Lindgren, and G. W. McElrath, both of the University of Minnesota
Extensive revision of this widely adopted text permits its use in courses requiring only algebra as a prerequisite, as well as courses requiring calculus. The basic goal remains the same: to provide a readable, teachable introduction to basic ideas of statistical inference and probability. A Solutions Manual is available.
1966, 288 pages, $7.95

Write to the faculty service desk for examination copies.

THE MACMILLAN COMPANY, **866 Third Avenue, New York, N.Y. 10022**

LINEAR SPACES OF ANALYTIC FUNCTIONS

PASQUALE PORCELLI • Louisiana State University

Approximation theory is the central theme of this monograph. Most of the theorems stated either lead to approximation theorems or are interesting results obtained from them. Designed to ground the student in analytic function theory and to familiarize him with both recent and historical literature.

1966

ELEMENTARY METHODS IN ANALYTIC NUMBER THEORY

A. E. GELFOND and U. V. LINNIK

Translated by Amiel Feinstein, Revised and Edited by L. J. Mordell

A systematized, simplified collection of results representing many different and important aspects of number theory. Illustrates the use of elementary methods in additive problems, problems of counting the number of integer points inside contours, and the distribution of primes. Each chapter is self-contained and may be read independently.

1965 • 242 pages • $8.75

AN INTRODUCTION TO MODERN MATHEMATICS

NATHAN J. FINE • Pennsylvania State University

This basic text presents concepts of modern mathematics to undergraduates through a balanced selection of topics and exercises. Fundamental concepts rather than techniques and manipulation are emphasized. Units are integrated by use of continuing themes; yet chapters may be rearranged to suit individual teaching methods. Numerous exercises provide theory applications; the Teacher's Manual contains complete solutions to all problems of any difficulty.

1965 • 509 pages • $8.50

LEADING PUBLISHERS SINCE 1868

THE ALLYN AND BACON SERIES
TOPICS IN CONTEMPORARY MATHEMATICS

This timely new series is composed of selected topics designed to facilitate instructional flexibility, and add to the enrichment of a variety of courses. Each topic has been chosen for its fundamental importance and interest to both professor and student. These short, paperbound volumes will introduce students to such topics as linear algebra, the real number system, probability, logic, and statistics.

CALCULUS: Part I

By EDWIN E. MOISE, *Harvard University.*

This text for first-year courses in elementary calculus is available in a complete edition and in two parts. *Part I* treats exponentials, logarithms, and trigonometric functions, and assumes *some,* but not a great deal of, prior knowledge of these topics. Ideas such as that of a coordinate system in a plane and mathematical induction are explained from the beginning. Nearly all ideas are introduced intuitively before being formalized, and figures are used freely in the exposition.

The book is, nevertheless, theoretically thorough in the sense that every topic introduced is eventually treated logically and exactly. There is a steady rise in the maturity level at which ideas are presented. Various abstract ideas are discussed at times when they are needed. Problems were composed by the author and are designed to teach the subject.

498 pp. 529 illus. $8.95

CALCULUS: Part II

By EDWIN E. MOISE, *Harvard University.*

Part II treats the calculus of several variables. Among the topics covered are infinite series, the discussion of which strongly emphasizes term-wise integration and differentiation and the differential equations which characterize the elementary functions of classical analysis. Discussions of linear algebra and solid analytic geometry with vectors, and a conventional short introduction to functions of several variables are also included.

Multiple integrals are stressed as the conceptually natural formulation of geometric and physical ideas, and the material on differential equations mainly emphasizes the real domain.

CALCULUS: Complete

By EDWIN E. MOISE, *Harvard University.*

In Press.

ALGEBRAIC STRUCTURES

By SERGE LANG, *Columbia University.*

This book is designed for use as a text in modern algebra. Together with the author's *Linear Algebra,* it constitutes a curriculum for an algebra program addressed to undergraduates. Although the present book is self-contained logically, it is perhaps advisable to take the linear algebra course *before* being introduced to the more abstract notions of groups, rings, and fields, and the systematic development of their basic abstract properties. Where overlap exists between this book and *Linear Algebra,* such as on groups of matrices and rings of endomorphisms, the emphasis is quite different.

173 pp. $6.95

INTRODUCTION TO TRANSCENDENTAL NUMBERS

By SERGE LANG, *Columbia University.*

The theory of transcendental numbers consists in determining the transcendence and algebraic independence of numbers obtained as values of classical functions, suitably normalized. This advanced text examines all of the several variations of the one main method of this theory. Applications range from a very elementary setting (concerning the function e^t), to rather sophisticated contexts involving abelian functions and automorphic functions.

105 pp. $7.50

INTRODUCTION TO DIOPHANTINE APPROXIMATIONS

By SERGE LANG, *Columbia University.*

The aim of this book is to illustrate by significant special examples three aspects from the theory of diophantine approximations: first, the formal relationships which exist between various counting processes and functions entering into the theory; second, the determination of these functions for numbers which are given as classical numbers; and third, certain asymptotic estimates holding almost everywhere (e.g. the Khintchine theorems and the Leveque-Erdös-Schmidt theorems).

LINEAR LATTICES *by Hidegorô Nakano*

Although there is continuing interest in the general theory of linear lattices, much of Professor Nakano's basic work on the subject has long been out of print. *Linear Lattices* has been published to facilitate further study. The book reprints the preliminary part of *Modulared Semi-Ordered Spaces* (Tokyo, 1950) and contains Professor Nakano's discussion of projectors, spectral representation theory, and reflexive and normed spaces.

New mathematics texts published by Prentice-Hall

THE STRUCTURE OF THE REAL NUMBER SYSTEM: A Programmed Introduction, *by John D. Baum, Oberlin College, and Roy a Dobyns, McNeese State College.* A self-instructional, programmed book on the real number systems following the recommendations of the C.U.P.M. Panel of teaching training. The authors' presentation is first descriptive and then axiomatic. Containing more than just the development of real number systems, the book includes some introductory material on set theory, truth sets, inequalities, coordinate systems, and functions. A teacher's manual is available. *April 1967, approx. 288 pp., $6.95*

INTEGRATED ALGEBRA AND TRIGONOMETRY: WITH ANALYTIC GEOMETRY, 2nd Edition, 1967, *by Robert C. Fisher, The Ohio State University, and Allen D. Ziebur, State University of New York at Binghampton.* A thorough revision of one of the most successful pre-calculus mathematics texts published (over 158,000 copies of the previous edition sold). The unifying theme of the text is the concept of the function and its graph. New to this edition are the introduction of the language and notation of sets, and the treatment of analytic geometry. *February 1967, approx. 448 pp., $8.95*

INTRODUCTORY COMPLEX ANALYSIS, *by Richard A. Silverman, formerly of the Courant Institute of Mathematical Sciences of New York.* A basic senior or first year graduate course in Complex Variable Theory and its applications. Completely self-contained, the text requires students to have a background in advanced calculus. Presents a thorough treatment of elementary functions, especially polynomials and rational functions, with separate chapters on harmonic functions, conformal mapping and analytic continuation. *January 1967, approx. 352 pp., $8.75*

INTRODUCTION TO CONTEMPORARY ALGEBRA, *by Marvin L. Tomber, Michigan State University.* Based on the structure of algebra, Dr. Tomber's underlying theme is the rational development of algebra as a fundamental human discipline. An informal development of algebra from the axioms of algebra, it has been prepared to meet the requirements of modern algebra courses as outlined by the Committee of the Undergraduate Program in Mathematics. *January 1967, approx. 448 pp., $7.95*

APPLIED DIFFERENTIAL EQUATIONS, 2nd Edition, 1967, *by Murray R. Spiegel, Rensselaer Polytechnic Institute.* "Spiegel's book is outstanding for its attempts at unified treatments of many topics, for its very good selection of exercises, and for its clarity in presenting techniques for solution of differential equations. . . . This book remains what it always was: one of the best of its type. . . . The additional material on numerical methods is very welcome." *From a Pre-Publication Review. January 1967, approx. 384 pp., $8.50*

MODERN ELEMENTARY STATISTICS, 3rd Edition, 1967, *by John E. Freund, Arizona State University.* While retaining the highly teachable, lucid aspects of the two previous editions, the new third edition has been almost completely rewritten. Its objectives, however, remain the same: to acquaint beginning students in the biological, social, and physical sciences with the fundamentals of modern statistics. Most of the illustrations and exercises are new. *January 1967, approx. 448 pp., $9.25; Answerbook, February 1967, 16 pp., $.50*

LINEAR TRANSFORMATIONS AND MATRICES, *by F. A. Ficken, New York University.* A new text presenting the basic theory of finite-dimensional real and complex linear spaces. For students taking a first "conceptual" course. The material has been class-tested by the author for over two years before final publication. *January 1967, approx. 368 pp., $10.50*

MAXIMUM PRINCIPLES IN DIFFERENTIAL EQUATIONS, *by Murray Protter, University of California, Berkeley, and Hans Weinberger, University of Minnesota, Minneapolis.* An elementary account of maximum principles for ordinary differential equations as well as elliptic, parabolic, and hyperbolic second order partial differential equations, and their applications. The authors stress applications to the numerical approximation of solutions and to error bounds in the application. *September 1967, approx. 256 pp., $8.00*

FOR YOUR MATH COURSES, HOLT OFFERS...

CALCULUS AND ANALYTIC GEOMETRY, Second Edition

ABRAHAM SCHWARTZ, The City College of the City University of New York

As in the first edition, this text for the introductory calculus course begins with chapters on the differential and integral calculus which rest on an intuitive basis rather than an abstract one. In this second edition, the definition of "function" at the beginning of the book has been rewritten in more precise terms, and the first, intuitive definition for integrals in Chapter Two has been improved.

March 1967 1024 pp. $11.95 tent.

INTRODUCTION TO NUMBER THEORY

JAMES E. SHOCKLEY, Virginia Polytechnic Institute

Designed for a one semester course in number theory, this text offers a good deal of exposition in its treatment of the subject. While maintaining rigor, proofs are treated in a more gradual style than the usual terse manner of presentation. Most of the chapters are virtually independent of each other, and can be treated in any sequence.

February 1967 256 pp. $7.95 (tent.)

A SURVEY OF COLLEGE MATHEMATICS

DONALD R. HORNER, Eastern Washington State College

Here is an introduction to mathematics that offers, at an elementary level, both an appreciation of mathematical abstractions and a broad survey of the main topics in mathematics. Some of the concepts of pure mathematics are developed in the first chapters where logic, set theory and basic number systems are introduced. Other chapters provide a review of high school mathematics and broad treatment of matrices and determinants, probability and statistics, analytic geometry, trigonometry, and elementary calculus.

March 1967 320 pp. $6.50 tent.

Announcing These New Additions to Harper's Series in Modern Mathematics

Israel N. Herstein and Gian-Carlo Rota, Editors

DIFFERENTIAL GEOMETRY

Louis Auslander

This treatment of classical differential of surfaces combines both modern and classical orientations. The first three chapters establish the algebraic and analytic prerequisites for the remaining material. Chapter III is unusual in treating Matrix Lie groups rather than Lie groups, thus providing the student with general results without unnecessary abstraction. Chapters IV and V treat the local theory of surfaces, first from a modern point of view, then from a classical one. The concluding chapters introduce the theory of manifolds through presentation of such subjects as non-euclidian geometry. *Coming in March*

CONSTRUCTIVE REAL ANALYSIS

Allen A. Goldstein

The central concern of this text, the first of its kind, is the ideas involved in developing constructions for solving the closely related problems of finding roots of systems of equations and operator equations in a given region, and the extremal problems of minimizing or maximizing functions defined on subsets of finite and infinite dimensional spaces. Rather than provide practical algorithms for solving problems, the aim here is to furnish tools for studying and developing algorithms. *Coming in April*

INTRODUCTION TO LINEAR ALGEBRA

Peter J. Kahn

Emphasis is on the development of mathematical insight and problem-solving capacity as the book proceeds from the specific to the general, the concrete to the abstract, the geometric to the algebraic. Illustrating this organization, the first chapter presents informally many examples while later chapters supply theoretical foundation; determinants are presented as scalar changes in oriented volume due to linear transformation (starting with a detailed examination of the real two-dimensional case), and algebraic consequences are then developed. *Coming in May*

ORDERED TOPOLOGICAL VECTOR SPACES

Anthony L. Peressini

This systematic treatment of the theory of ordered topological vector spaces brings together information largely available only in scattered research papers. The text includes motivational material and many examples and applications which make it useful to graduate students who have completed only an introductory course in functional analysis. There is detailed discussion of vector lattices, Choquet simplexes, order convergence, continuity and extensive properties of positive linear mappings and functionals, topological convergence of monotone families, normal cones, order topologies, and order properties of spaces of continuous linear mappings. *Coming in June*

Harper & Row, Publishers 150th ANNIVERSARY **49 E. 33d St., N.Y. 10016**

CASPER GOFFMAN

Calculus of Several Variables

"A beautifully written book, written by a master mathematician. We need more books like this one. I intend to use it as a text the next time I teach this material." *Professor A. W. Goodman, University of South Florida* 185 pages; $7.00

Introduction to Real Analysis

The text presents, for upperclass students, many significant concrete theorems and, along with continuity, differentiation, and integration, treats both Power series and Fourier series at a depth not customary at this level of instruction. Equally useful either as a separate text or in combination with *Calculus of Several Variables* to form the complete undergraduate course in real calculus. 160 pages; $7.50

A. H. LIGHTSTONE

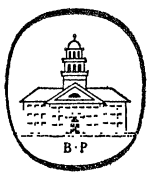
Concepts of Calculus I

This unified treatment of calculus uses one argument and develops the subject in a logical, consistent manner. Concepts of calculus are clarified by using elementary set ideas and set notation. Two themes dominate: the notion of a function and that of the limit of a sequence. 544 pages; $8.75

Concepts of Calculus II

Beginning with a discussion of axiomatic method and modern algebra, followed by a substantial treatment of linear algebra, the text presents the calculus of functions with several arguments. Numerical approximations are stressed, an efficient predictor-corrector method is used for the numerical solution of a first-order differential equation, and many problems are solved using an automatic digital computer.
502 pages; $8.75

Symbolic Logic and the Real Number System



"A. H. Lightstone has two primary objectives: to set forth 'the impact of symbolic logic on mathematics' and 'to develop the real number system on the basis of ordinary arithmetic.' This exposition should lead the reader to a real feeling for the concepts of logic rather than merely an ability to manipulate." *Science* 225 pages; $7.50

ANTHONY R. LOVAGLIA and GERALD C. PRESTON

Foundations of Algebra and Analysis: an elementary approach

This text covers the mathematics fundamental to courses in algebra and analysis, particularly to the calculus sequence. Beginning with a chapter on elementary logic and sets, it proceeds through the usual number systems, functions, polynomials, trigonometry, and finite and infinite sets, considering matrices in the final chapter.
516 pages; $8.95

Harper & Row, Publishers 150th ANNIVERSARY **49 E. 33d St., N.Y. 10016**

Mathematics Texts from Blaisdell

COMBINATORIAL THEORY

Marshall Hall, *California Institute of Technology*

Intended for advanced undergraduate and beginning graduate students, the text covers a branch of discrete mathematics. Prerequisites to this material are linear algebra and probability. Among the topics included: theory of permutations and combinations, theory of partitions and material relevant to design of experiment, linear programming, and finite geometries. *In press.*

NUMERICAL INTEGRATION

Philip J. Davis, *Brown University*
Philip Rabinowitz, *Weizmann Institute, Israel*

This monograph provides a balance between practical applications and theoretical topics, which underlie numerical integration. The coverage is broad, comprehensive, and computer oriented. The Appendix includes FORTRAN programs, a bibliography of ALGOL procedures, and a reproduction of "On the Practical Evaluation of Integrals" by M. Abramowitz. *Available January*

STATISTICAL COMPUTATIONS ON A DIGITAL COMPUTER

William J. Hemmerle, *University of Rhode Island*

This text is useful to both statisticians and to numerical analysts. The statistical theory is briefly presented for various applications which are selected because of their importance in applied statistics and numerical analysis. A basic knowledge of computer programming and some advanced calculus and matrix algebra are assumed. *Available April*

INTRODUCTION TO ALGEBRA

Sam Perlis, *Purdue University*

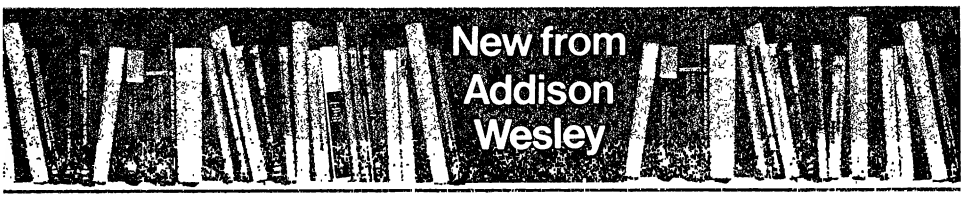
Designed for an introductory course in modern algebra or separate courses in linear and abstract algebra, this text presents the concepts and elementary facts of five systems: groups, rings, integral domains, fields, and vector spaces. Coverage extends to low-level topics such as induction, roots of unity, multiple roots of polynomials, and irreducibility. Matrices are used to move from the concrete to the abstract; repetition and examples clarify advanced concepts. *1966. 440 pages. $9.50*

INTRODUCTION TO ORDINARY DIFFERENTIAL EQUATIONS

Shepley Ross, *University of New Hampshire*

This text covers essentially the first nine chapters of the author's larger work, DIFFERENTIAL EQUATIONS. It treats the most fundamental methods of elementary differential equations, but omits the more advanced, specialized, and theoretical topics which would be presented in an intermediate course. However, such specialized topics as numerical methods and Laplace Transform are included. *1966. 337 pages. $7.50*

PROBLEMS IN GROUP THEORY



John Dixon, *University of New South Wales*

This book supplements group theory texts now available by providing a generous source of challenging problems. The problems illustrate methods and techniques used in many branches of group theory and enable the student to become familiar with the applications of the theorems which he is studying. *In press.*

BLAISDELL PUBLISHING COMPANY

A Division of Ginn and Company

275 Wyman Street, Waltham, Massachusetts 02154

MATHEMATICS FOR LIBERAL ARTS

By MORRIS KLINE, *New York University.*

Intended for liberal arts and terminal students, this book is a revision and abridgement of the author's *Mathematics: A Cultural Approach.* This revision aims to meet special needs: courses for students who should have a little more review and drill on elementary concepts and techniques, courses for elementary school teachers, and one-semester twelfth-year high school or college courses.

The book offers a review of high school algebra and geometry and a selection of topics from trigonometry, analytic geometry, projective geometry, calculus, non-Euclidean geometry, other algebras, statistics and probability.

In Press.

MATHEMATICS FOR ELEMENTARY TEACHERS: AN INTRODUCTION

By G. CUTHBERT WEBBER, *University of Delaware.*

Intended for elementary school and in-service teachers, or as a supplement to content and methods courses for elementary school personnel, this book lays a foundation for both present-day and traditional courses. The text discusses the mathematics which underlies mathematical topics taught in elementary school curricula, tying together arithmetic ideas usually treated as unrelated topics. In Press.

ELEMENTARY CALCULUS FROM AN ADVANCED VIEWPOINT

By GEORGE B. THOMAS, JR., *Massachusetts Institute of Technology,* JOHN K. MOULTON, *Brookline High School, Massachusetts,* and MARTHA ZELINKA, *Weston High School, Massachusetts*

This text grew out of a series of lectures given to high school teachers of advanced placement calculus, and is intended to provide a deeper understanding of elementary calculus. The main purpose of the book is to show the structure of elementary calculus and its analytical foundations. Theoretical ideas are carefully explained and motivated, and applied to particular problems. In Press.

MATRICES AND LINEAR TRANSFORMATIONS

By CHARLES G. CULLEN, *University of Pittsburgh.*

The first five chapters of this book on linear algebra comprise a one-term text for science, engineering and mathematics students which covers those topics most frequently encountered in applications. Only a first course in calculus and analytic geometry is required. Aimed at the sophomore-junior level, the text approaches the subject from the matrix theory point of view rather than from the more abstract approach using linear transformations.

227 pp. $8.95

INTRODUCTION TO ANALYTIC FUNCTIONS

By WILFRED KAPLAN, *University of Michigan.*

The present book is designed to provide an elementary introduction to functions of complex variables and their applications, for senior and graduate students of science and engineering. The text is based directly on Chapter Nine of the author's *Advanced Calculus,* and also includes a completely new chapter on analytic functions of several complex variables, coverage rarely made accessible at this level.

212 pp. 78 illus. $7.95

INTRODUCTION TO LINEAR ANALYSIS

By DONALD L. KREIDER, *Dartmouth College,* ROBERT G. KULLER, *Wayne State University,* DONALD R. OSTBERG, *State University of New York at Buffalo,* and FRED W. PERKINS, *Dartmouth College.*

This book, which assumes a background in calculus, is designed to serve as an introductory text in applied analysis for students of science and engineering. It covers much of the traditional material, however it also treats topics which are of importance in present day mathematics. The concept of linearity is emphasized and used as a unifying thread which ties together the treatment of topics often presented in an isolated manner. Conceptual understanding is stressed throughout.

THE SIGN OF EXCELLENCE

TOPOLOGY: AN INTRODUCTION WITH APPLICATIONS TO TOPOLOGICAL GROUPS.
By GEORGE McCARTY, University of California at Irvine.

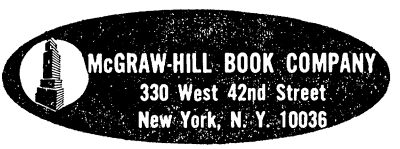
This new, introductory text helps the student to develop his geometric intuition and shows him how to translate it into the solid arithmetic of a proof. It carries a beginning student through a sustained geometric development to a concluding theorem which draws on nearly the entire contents of the book. The first part covers the elements of "point set" or "general" topology. The second half applies the techniques of point-set topology to homotropy theory and topological groups. Clarity is ensured by the informal, lucid presentation and by extensive diagrams and worked-out examples. Exercises and practice problems are also provided.
Winter.

COLLEGE ALGEBRA, 5th Edition.
By PAUL K. REES, Louisiana State University, and FRED W. SPARKS, Texas Technological College.

The new edition of this fine text features the rigorous axiomatic approach, using modern terminology and the theory of sets rather than the traditional, rather loose approach. The result is a highly teachable text with proper motivation, numerous illustrations and illustrative examples. Clearly and concisely it presents the topics essential for further progress in mathematics and for the successful pursuit of courses in science and engineering. Graded problems are provided a normal lesson apart, with the degree of difficulty increasing gradually through the exercise.
Winter.

ALGEBRA, TRIGONOMETRY AND ANALYTIC GEOMETRY.
By PAUL K. REES, Louisiana State University, and FRED W. SPARKS, Texas Technological College.

Using the axiomatic approach, this introductory text presents the basic concepts of algebra, trigonometry and analytic geometry necessary for the successful study of calculus. The first 26 chapters are from the author's ALGEBRA AND TRIGONOMETRY (McGraw-Hill, 1962) and the remainder presents the geometry background necessary for a course in analytic geometry or calculus. While principles and methods of procedure are fully developed and illustrated, this is a reasoning approach rather than a rule book. There are 82 exercise sets with some 2800 problems arranged according to difficulty.
Winter.



FUNDAMENTAL MATHEMATICS, 3rd Edition.
By THOMAS L. WADE and HOWARD E. TAYLOR, both of Florida State University.

In the third edition of this highly successful introductory college mathematics text, the topics covered now proceed from a basis in sets and are discussed using modern terminology. The authors have succeeded in presenting the modern viewpoint without unduly raising the level of the text. The book is thoroughly revised and expanded, with increased emphasis on structure or pattern in fundamental mathematics and an increased use of the concept of set, set operations, and set symbolism. A proper balance is maintained between teaching for understanding and for manipulative techniques. **Winter.**

MODERN GEOMETRY. 2nd Edition.
By CLAIRE ADLER, Long Island University and C. W. Post College.

Revised throughout, this helpful text demonstrates the great discoveries and developments that followed Euclid. It meets the specific needs of prospective teachers of secondary curriculum and is also an excellent way for specialists in other disciplines to round out their geometric background. The book covers integrated theory of Euclidean, non-Euclidean and projective geometry. This edition highlights the close relationship between coordinate projective geometry and linear algebra, and also offers a new approach to coordinate geometry that eliminates many of the older, clumsier methods of algebraic geometry. **Winter.**

EXAMINATION COPIES AVAILABLE ON REQUEST

SPRING 1967

MODERN COLLEGE ALGEBRA

SECOND EDITION

by

ELBRIDGE P. VANCE

Oberlin College

When the first edition of this highly successful college algebra text was being written, the influence of CUPM, SMSG, and the Commission on Mathematics of the College Entrance Examination Board upon mathematics at this level was already seriously felt. Since that time, certain other suggestions have been made by various influential groups. It is because of the changing mathematical world, and the suggested introduction of additional new topics that a new edition of this book seemed appropriate.

Special Features of Second Edition . . .

1. This edition has included new material on matrices, and a new approach to vectors, both strongly recommended at this level and both perfect preparation for later courses in linear algebra.
2. Several references are made to computing machines and methods used in this field.
3. The problems in this new edition have been augmented. Also, there are four new sets of review problems included at appropriate places.
4. Some problems emphasize the important ability to manipulate, while others deal with more theoretical ideas.

This text for a first course not only covers the essentials of algebra, but also attempts to instill in the student an appreciation of algebra as a logical subject. The importance of developing computational skill, as a basis for future courses, is not overlooked. To this end adequate time is devoted to manipulative work, without diminishing the student's interest, and ample problems are provided.

Perhaps the most unusual feature of the book is the author's use of the postulational approach. Although not emphasized, the notion of sets is introduced at the beginning and used throughout. The order axioms, along with a detailed discussion of inequalities, are presented. Enough use is made of coordinate systems to lend more significance to the study of equations. The concepts of function and relation are introduced early, and are an integral part of the exposition throughout the remainder of the book.

TABLE OF CONTENTS

Sets and Numbers
The Algebra of Numbers as a Logical System
Extensions of the Logic of Algebra
Inequalities, Absolute Values, and Coordinate Systems
Functions and Their Graphical Representation
Linear and Quadratic Functions
Determinants
Polynomial Functions
Inverse Functions
Permutations, Combinations, and the Binomial Theorem
Mathematical Induction
Exponential and Logarithmic Functions

THE AMERICAN MATHEMATICAL MONTHLY

(FOUNDED IN 1894 BY BENJAMIN F. FINKEL)

R. A. ROSENBAUM, *Editor*

EDITORIAL CORRESPONDENCE AND MANUSCRIPTS OF PAPERS should be addressed to the Editor, R. A. Rosenbaum, Wesleyan University, Middletown, Conn. 06457.

ADVERTISING CORRESPONDENCE should be addressed to RAOUL HAILPERN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

NOTICE OF CHANGE OF ADDRESS by members of the Association as well as correspondence regarding subscriptions to the MONTHLY should be sent to the Executive Director, H. M. GEHMAN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

THIS IS THE OFFICIAL JOURNAL OF THE

MATHEMATICAL ASSOCIATION OF AMERICA, INC.

(Devoted to the Interests of Collegiate Mathematics)

General Office: SUNY at Buffalo, Buffalo, N. Y. 14214. *Executive Director:* H. M. GEHMAN

OFFICERS OF THE ASSOCIATION

President, E. E. MOISE, Harvard University
Past-President, R. L. WILDER, University of Michigan
First Vice-President, G. S. YOUNG, Tulane University
Second Vice-President, R. J. WALKER, Cornell University
Editor, R. A. ROSENBAUM, Wesleyan University
Secretary, H. L. ALDER, University of California, Davis
Treasurer, H. M. GEHMAN, State University of New York at Buffalo
Associate Secretary, RAOUL HAILPERN, State University of New York at Buffalo

Additional Members of the Board of Governors: J. J. ANDREWS, R. G. BARTLE, DOROTHY L. BERNSTEIN, R. H. BING, D. W. BLAKESLEE, E. A. CAMERON, E. J. CAMP, D. E. CHRISTIE, HARVEY COHN, R. B. DEAL, WADE ELLIS, K. W. FOLLEY, CALVIN FOREMAN, EMIL GROSSWALD, R. C. JAMES, P. S. JONES, D. E. KIBBEY, VICTOR KLEE, A. T. LONSETH, L. F. MCAULEY, N. H. MCCOY, D. W. MILLER, J. M. H. OLMSTED, C. R. PHELPS, G. B. PRICE, P. K. REES, ABRAHAM SCHWARTZ, L. L. SCOTT, M. F. SMILEY, F. M. STEIN, A. F. STREHLER, A. W. TUCKER, C. J. VANDERLIN, JR., D. W. WALL, J. R. WESSON, G. N. WOLLAN, MARTIN WRIGHT.

Annual dues for members of the Association (including a subscription to the American Mathematical Monthly) are $6.00. For nonmembers the subscription price is $10.00.

PUBLISHED BY THE ASSOCIATION at Menasha, Wisconsin, and Buffalo, N. Y. during the months of January, February, March, April, May, June–July, August–September, October, November, December.

Second-class postage paid at Menasha, Wisconsin. Acceptance for mailing at special rate of postage provided for in the Act of February 28, 1925, embodied in Paragraph 4, Section 538, P. L. and R., authorized April 1, 1926.

RECENT ADVANCES IN DIFFERENCE SETS

H. B. MANN, Mathematics Research Center, U. S. Army, University of Wisconsin

A difference set (v, k, λ) in a finite group G of order v is a set of elements $a_1, \cdots, a_k$ of G such that the equation

$$a_i a_j^{-1} = g$$

has exactly λ solutions for every $g \in G$, $g \neq 1$. It is easy to check that the blocks $B_g = (a_1 g, \cdots, a_k g)$ form a balanced incomplete block design (bib) with parameters v, k, λ. Hence we have

$$\lambda(v - 1) = k(k - 1). \tag{1}$$

According to Schuetzenberger [5] we also know, that *if v is even then $k-\lambda$ is a square.*

The incidence matrix of a (bib) with parameters $(4N-1, 2N-1, N-1)$ can be used to construct Hadamard matrices of order $4N$. To do this one replaces the zeros of the incidence matrix by -1 and borders the resulting matrix by a row and a column of 1's. Other Hadamard matrices may be obtained directly (without bordering) from (bib) designs with parameters $4N^2$, $2N^2-N$, N^2-N. Hadamard matrices have been used in the construction of binary codes [4], and there is no reason why other (bib) designs should not prove advantageous especially in asymmetric channels. It seems also reasonable to expect that codes constructed from groups and especially from Abelian groups will be relatively easy to implement. Apart from its intrinsic interest as a problem in combinatorial analysis, therefore, the construction of difference sets and the question of their existence for certain parameter combinations is of interest in the theory of error correcting codes.

We shall restrict ourselves here principally to Abelian groups because not much is known about difference sets in non-Abelian groups. The difference sets with $k = v$ and with $k = v - 1$ are called trivial and will not be considered here. It is easy to see that the complement of every difference set is a difference set so that we may always assume $k < v/2$. The research here goes in two directions: The construction of new sets, and the proof of the impossibility of solutions for certain parameter combinations. While progress in construction of difference sets was comparatively slow, an impressive number of theorems ruling out many infinite classes of parameter combinations have been obtained in recent years. These impossibility proofs sometimes refer to all Abelian groups and sometimes to specific groups only. Cyclic and elementary Abelian groups have received special attention. A complete result has been obtained for groups of order 2^m. It has been shown [3] that the only possible solutions for v, k, λ are $v = 2^{2m}$, $k = 2^{2m-1} - 2^{m-1}$, $\lambda = 2^{2m-2} - 2^{m-1}$. Difference sets for these parameter combinations can be constructed easily in groups which are the direct products of four-groups and of cyclic groups of order 4. According to R. Turyn [7] one can take

all elements of a direct product of m of these groups for which an odd number of components are unit elements. These difference sets yield Hadamard matrices directly. Very few solutions are known in other groups of order 2^{2m}. At any rate, by Corollary 2.3, the exponent of such a group is at most 2^{m+1} so that there are no cyclic solutions except the trivial ones.

Another set of solutions likely to be useful in coding are the difference sets of Stanton and Sprott [6]. If $p^n+2=q^m$, p, q primes then we consider the additive group of the direct product R of G.F.$(p^n)\times$G.F.(q^m). Let x be a primitive root of G.F.(p^n) and y a primitive root of G.F.(q^m). Write the elements of R as pairs (a, b), $a\in$G.F.(p^n), $b\in$G.F.(q^m) and put $z=(x, y)$, $s=p^n$. Then

$$z^0, z^1, \cdots, z^{(s^2-3)/2}, (0, 0), (1, 0), \cdots, (x^{s-2}, 0)$$

is a difference set for the additive group of R with parameters $v=p^nq^m$, $k=(v-1)/2$, $\lambda=(v-3)/4$. These sets also lead to Hadamard matrices.

Another difference set that yields an Hadamard matrix consists of the squares of G.F.(p^m) where $p^m\equiv 3(4)$.

In 1956 Marshall Hall [1] published an enumeration of all cyclic difference sets with $k\leqq 50$, which left 12 cases undecided. It is a rather curious fact that only in 1962 these problems were attacked, and simultaneously by four researchers. The most satisfactory solution was obtained by K. Yamamoto [8] who disposed at once of all of Hall's 12 cases by one theorem on congruence relations in cyclotomic fields.

To formulate Yamamoto's theorem consider a function $C(i)$ which vanishes except when i is an integer. Such a function will be called a number-theoretic function. We define

$$\Delta(\rho) = C(i+\rho) - C(i).$$

We shall denote the field of rational numbers by R, and ζ_m will denote a primitive mth root of unity. Yamamoto's theorem runs as follows:

THEOREM 1 (Yamamoto). *Let $N=p_1^{e_1}\cdots p_r^{e_r}$ be the prime power decomposition of N. Let m be relatively prime to N, C a periodic number-theoretic function with period N whose values $C(i)$ are integers of $R(\zeta_m)$ and $f(x)=\sum_{i=0}^{N-1} C(i)x^i$. Moreover let d be a divisor of N and α an integer of $R(\zeta_m)$.*

Then, in order that $f(\zeta_N^t)\equiv 0(\alpha)$ for all divisors t of d, it is necessary and sufficient that

$$p_1^{t_1}\cdots p_r^{t_r}\Delta(Np_1^{-t_1-1})\Delta(Np_r^{-t_r-1})C(i) \equiv 0(\alpha) \tag{2}$$

for all i and for all $t_1, \cdots, t_r$ such that $d\equiv 0\ (p_1^{t_1}\cdots p_r^{t_r})$.

Applying Yamamoto's theorem to the case $d=1$ and $m=1$ one easily proves by induction:

COROLLARY 1.1. *If u is a rational integer, $\sum C(i)\zeta_N^i\equiv 0(u)$, $\sum C(i)\zeta_N^{(i)}\neq 0$ and if $|C(i)|\leqq M$ then $u\leqq 2^rM$, if $0\leqq C(i)\leqq M$ then $u\leqq 2^{r-1}M$.*

To apply the corollary to Abelian groups in general we consider the group ring $R(G)$ over a ring R of an Abelian group G. The group ring $R(G)$ consists of expressions of the form $\sum_{g\in G} a_g g$, $a_g \in R$. We define

$$\sum_{g\in G} a_g g + \sum_{g\in G} b_g g = \sum_{g\in G} (a_g + b_g)g, \qquad \sum_{g\in G} a_g g \sum b_g g = \sum_{g^*\in G} g^* \sum_{gg'=g^*} a_g b_{g'}.$$

If D is any set of G we shall write $D(t) = \sum_{g\in D} g^t$. If D is a difference set then

$$D(1)D(-1) = n + \lambda G, \tag{3}$$

where $n = k - \lambda$ and n stands for n times the identity of G.

A character χ of an Abelian group G is a mapping of G into a group of roots of unity. The character χ given by $\chi(g) = 1$, $g \in G$ is called the principal character and will be denoted by χ_0. If $g_1, \cdots, g_t$ is a basis of G, the character χ is defined when $\chi(g_i)$ is defined and we may choose for $\chi(g_i)$ any root of unity whose order divides the order of g_i. We define the product of two characters χ, χ' by

$$\chi\chi'(g) = \chi(g)\chi'(g).$$

Under this definition the characters themselves form a group isomorphic to G. Now let R be a ring whose elements are numbers. We extend the definition of the characters χ to the group ring. If

$$A = \sum_{g\in G} a_g g$$

then we define $\chi(A) = \sum_{g\in G} a_g \chi(g)$.

A character maps the group ring homomorphically into a cyclotomic field. One easily establishes the inversion formula: *If v is the order of G and*

$$A = \sum a_g g \tag{4}$$

then

$$a_g = \frac{1}{v} \sum_{\chi} \chi(A)\chi(g^{-1}). \tag{5}$$

Now let R be the ring of integers of a number field F and let $\mathfrak{M}$ be an ideal in R. From (5) one easily gets

LEMMA 1. *If $(\mathfrak{M}, v) = 1$ and $\chi(A) \equiv 0(\mathfrak{M})$ for all characters χ then $a_g \equiv 0(\mathfrak{M})$. If $\chi(A) \equiv 0(\mathfrak{M})$ for all nonprincipal characters χ then*

$$A = \mu G(1) + M, \qquad \mu \in R, \qquad M \in R(G), \tag{6}$$

where all coefficients of M are in $\mathfrak{M}$.

We now proceed to prove a theorem of Turyn [7].

THEOREM 2 (TURYN). *Let v be the order of G and D any subset of G, m a rational integer, χ_1 a character of order v_1, r the number of distinct prime factors of v_1, $\hat{H}$ a*

group of characters of G of order v_2, $(m, v_2)=1$, $\chi_1^j \notin \hat{H}$ if $\chi_1^j \neq \chi_0$.

If $r \geqq 0$, $\chi\chi_1(D) \neq 0$ for at least one χ and $m \mid \chi\chi_1(D)$ for all $\chi \in \hat{H}$ then

$$2^{r-1}v \geqq mv_1v_2. \tag{7}$$

If $r \geqq 0$, $\chi\chi_1(D) \neq 0$ for at least one nonprincipal χ and $m \mid \chi\chi_1(D)$ for all nonprincipal characters $\chi \in \hat{H}$ then

$$2^r v \geqq mv_1v_2. \tag{7a}$$

We first prove

LEMMA 2. *Let H be the kernel of $\hat{H}$ and set*

$$\psi(g_1) = \sum_{g \in Hg_1} y_g \chi_1(g), \tag{8}$$

where $D(1) = \sum_{g \in G} y_g g$. If $m \mid \chi\chi_1(D)$ for all $\chi \in \hat{H}$ then for all $g \in G$

$$\psi(g) \equiv 0(m). \tag{9}$$

If $m \mid \chi\chi_1(D)$ for all nonprincipal $\chi \in \hat{H}$ then for any pair g_1, g_2 in G

$$\psi(g_1) \equiv \psi(g_2)(m). \tag{10}$$

Proof. The characters χ of $\hat{H}$ can be considered as the group of characters of the factor group $G/H = H^*$ consisting of the cosets Hg of H. Consider the element

$$A = \sum_{h^* \in H^*} h^* \sum_{g \in h^*} y_g \chi_1(g)$$

of the group ring of H^* over the integers of $R(\zeta_{v_1})$. For any character χ in $\hat{H}$ we then have

$$\chi(A) = \sum_{h^*} \sum_{g \in h^*} y_g \chi\chi_1(g) = \sum_{g \in G} y_g \chi\chi_1(g) = \chi\chi_1(D). \tag{11}$$

Lemma 2 now follows from Lemma 1 and equation (11).

We now prove the theorem of Turyn. Let

$$\psi(g_1) = \sum_{g \in Hg_1} y_g \chi_1(g) = \sum_{i=0}^{v_1-1} Y_i \zeta_{v_1}^i.$$

If $g \in Hg_1$, $\chi_1(g) = \zeta_{v_1}^i$, $\chi \in \hat{H}$ for fixed i then $\chi\chi_1(g) = \chi(g_1)\zeta_{v_1}^i$. Hence all these g lie in the same coset modulo the kernel of $\hat{H} \times \{\chi_1^j\}$. But the assumptions of our theorem imply that the order of this kernel is v/v_1v_2. Hence $Y_i \leqq v/v_1v_2$. From (11) it also follows that $\chi(A) \neq 0$ for at least one χ, hence $\psi(g) \neq 0$ for at least one g in the first case and $\psi(g_1) \neq \psi(g_2)$ for at least one pair g_1, g_2 in the second case. Theorem 2 now follows from Lemma 2 and Corollary 1.1.

We now return to our difference sets. From (3) we have for all nonprincipal characters χ of G

$$\chi(D(1))\chi(D(-1)) = n. \tag{12}$$

Now let $v \equiv 0(v_2)$, let χ be a nonprincipal character whose order is a divisor of v_2 and assume that

$$n \equiv 0(p^j), \qquad n \not\equiv 0(p^{j+1}), \tag{13}$$

where $v_2 = p^\alpha v_1$, $\alpha \geqq 0$ and $p^\beta \equiv -1(v_1)$ for some $\beta \geqq 0$. Then the automorphism $\zeta_{v_2} \to \zeta_{v_2}^{-1}$ of $R(\zeta_{v_2})$ leaves all prime factors of p invariant so that 12 implies that

$$\chi(D) \equiv 0(p^{j/2}). \tag{14}$$

A prime p for which $v_2 = p^\alpha v_1$, $p^\beta \equiv -1(v_1)$ will be called self-conjugate mod v_2. If all prime factors of an integer m are self conjugate mod v_2 then m is called self-conjugate mod v_2.

We now derive the following corollaries of Theorem 2.

COROLLARY 2.1. *If there is in G a difference set (v, k, λ), if $p \mid n$ and p is a prime self conjugate* mod v^* *where v^* is the exponent of G, then the highest power of p dividing n is even. If $p^{2s} \mid n$, the p exponent of G is p^e and $v = p^t w$, $(p, w) = 1$ then*

$$p^{s+e} \leqq p^t. \tag{15}$$

(This means in particular that the p component of G cannot be cyclic.)

Proof. If $w > 1$ then the first part of the theorem is true because p has no multiple factors in $R(\zeta_w)$. If $w = 1$ then it follows from the equation $\lambda p^t = k^2 - n$.

Now in Theorem 2 let $\hat{H}$ be the subgroup of characters of order w and let χ_1 be any character of order p^e. Then if $\chi_1 \neq \chi_0$ we have $\chi\chi_1(D) \equiv 0(p^s)$ for all $\chi \in \hat{H}$ and if $\chi_1 = \chi_0$ then $\chi\chi_1(D) \equiv 0(p^s)$ for all nonprincipal $\chi \in \hat{H}$ whence $p^s p^e w \leqq p^t w$, $p^{s+e} \leqq p^t$.

COROLLARY 2.2. *Let D be a difference set in a group which has a character of order w. Let $m^2 \mid n$ and let m be self conjugate* mod w. *If $(m, w) > 1$ then $wm \leqq 2^{r-1}v$, where r is the number of distinct prime factors of (m, w). If $(m, w) = 1$ then $wm \leqq v$.*

Proof. Let $w = v_1 v_2$ where v_1 is a product of prime powers dividing (m, w), (if there are any) and $(v_2, m) = 1$. Let χ_1 be a character of order v_1 and χ_2 of order v_2. In Theorem 2 let $\{\chi_2^j\} = \hat{H}$ and the corollary follows.

An Hadamard matrix can be constructed from a difference set $4p^{2s}$, $2p^{2s} - p^s$, $p^{2s} - p^s$. We shall refer to such sets as Hadamard sets. We have

COROLLARY 2.3. *Let D be an Hadamard set in a group G. If $v = 4p^{2s}$, p a prime, and if p^e is the p exponent of G, then $e \leqq s+2$ if $p = 2$ and $e \leqq s$ if $p \neq 2$.*

For proof we may, in Theorem 2, put $v_1 = 2^e$, $v_2 = 1$ for $p = 2$ and $v_1 = p^e$, $v_2 = 2$ for $p > 2$.

Corollaries 2.1 and 2.2 suffice to dispose of all of Marshall Hall's [1] unsolved cases, disposing in a number of cases not only of cyclic difference sets but of other Abelian sets and sometimes of all Abelian sets as well. Corollary 2.3 shows

that there are no circulant Hadamard matrices when n is a prime-power unless $n=1$. (The conjecture that there are no circulant Hadamard matrices unless $v=4$ is still unproved.)

About two years ago I investigated difference sets in elementary Abelian groups. We already mentioned that the Hadamard sets $v=2^{2m+2}$, $k=2^{2m+1}-2^m$, $\lambda=2^{2m}-2^m$ are the only nontrivial sets in elementary Abelian groups of order 2^t for any t. It is also easy to check that the squares of G.F.(m) form a difference set $(m, (m-1)/4, (m-3)/4)$ in the additive group of G.F.(m) if $m\equiv -1(4)$. For difference sets in elementary Abelian groups of order p^m, $p\equiv 1(2)$ the following theorem holds. We recall that the number t is multiplier of D if $D(t)=gD(1)$ for some $g\in G$.

THEOREM 3. *If the quadratic residues* mod p *are multipliers of the elementary Abelian difference set D with parameters p^m, k, λ, then the equation*

$$x^2 + py^2 = 4n \tag{16}$$

is solvable. Let $(x_1, y_1), \cdots, (x_l, y_l)$ be the solutions of (16) *then*

$$k + \tfrac{1}{2}(p-1)(x_1z_1 + \cdots + x_lz_l) = \epsilon p^m, \tag{17}$$

where $z_1, \cdots, z_l$ are nonnegative integers and ϵ may take either the value 0 *or the value* 1 *(but not both) and*

$$z_1 + \cdots + z_l = (p^m - 1)/(p - 1). \tag{18}$$

COROLLARY 3.1. *If $l=1$ then $k=(p^m-1)/2$.*

COROLLARY 3.2. *If $p>3$ then n is not a prime.*

A family of cases in which the condition of Theorem 3 holds is given by

THEOREM 4. *If $p=2q+1$, q a prime and if no prime divisor of n is congruent to* 1 mod p *then the quadratic residues* mod p *are multipliers of any elementary Abelian difference set (p^m, k, λ) and n is not a prime if such a difference set exists.*

A search for noncyclic elementary Abelian difference sets with $v\leqq 2500$, $v\equiv 1(2)$ failed to produce any solutions except for the parameters p^m, $(p^m-1)/2$, $(p^m-3)/4$. Corollary 2.1 together with Theorem 3 and its corollaries rule out all but 9 of the other solutions of (1). Since the completion of my paper, 6 of the nine cases have been ruled out by R. J. Turyn and one by A. Gleason. The only open cases with $v\leqq 2500$ are 31^2, 256, 68 and 3^6, 273, 102. This gives some support to the conjecture that no elementary noncyclic Abelian set exists unless either $v=2^{2m+2}$, $n=2^{2m}$ or $v=p^m$, $k=(p^m-1)/2$.

This work was sponsored by the Math. Research Center, U. S. Army, Madison, Wisconsin.

ON CONVOLUTED NUMBERS AND SUMS

DAVID ZEITLIN, University of Minnesota

1. Preliminaries. Recently, Arkin [1], defining numbers $C_n^{(k)}$ by the identity

$$(1.1) \qquad (1 - x - x^2)^{-k} = \sum_{n=0}^{\infty} C_n^{(k)} x^n \quad (k = 1, 2, \cdots),$$

gave four relations involving $C_n^{(k)}$, where for $k=1$, $C_n^{(1)} = F_{n+1}$, the Fibonacci sequence defined by $F_{n+2} = F_{n+1} + F_n$, $n = 0, 1, \cdots$, with $F_0 = 0$ and $F_1 = 1$. It should be noted that the numbers $C_n^{(k)}$ are not new; they have appeared previously (but in a different notation) in the paper by Riordan [2, pp. 11–12], who refers to $C_n^{(k)}$ as the "kth convoluted Fibonacci number," because the left side of (1.1) is the kth power of the generating function for Fibonacci numbers. Thus, we obtain from (1.1) the following convoluted sum identity:

$$(1.2) \qquad C_n^{(k)} = \sum_{i_1+i_2+\cdots+i_k=n} F_{1+i_1} F_{1+i_2} \cdots F_{1+i_k},$$

where the ordered set of indices $i_1, i_2, \cdots, i_k$ assume the values of all permutations of all sets of k nonnegative integers whose sum is n. Alternatively, one could write (1.2) as

$$C_n^{(k)} = C_n^{(1)} * C_n^{(k-1)} = \sum_{j=0}^{n} C_j^{(1)} C_{n-j}^{(k-1)} = C_n^{(1)} * C_n^{(1)} * \cdots * C_n^{(1)},$$

where $H_n * G_n$ is the convolution (defined above) of the sequences $(H_0, H_1, \cdots)$ and $(G_0, G_1, \cdots)$.

Recalling that

$$(1 - y)^{-k} = \sum_{j=0}^{\infty} \binom{k-1+j}{k-1} y^j,$$

we see that for $y = x + x^2$,

$$(1.3)\qquad \begin{aligned}(1-x-x^2)^{-k} &= \sum_{j=0}^{\infty}\binom{k-1+j}{k-1}(x+x^2)^j \\ &= \sum_{j=0}^{\infty}\binom{k-1+j}{k-1}\sum_{i=0}^{j}\binom{j}{i}x^{i+j} \\ &= \sum_{n=0}^{\infty}x^n\sum_{m=0}^{[n/2]}\binom{k+n-1-m}{k-1}\binom{n-m}{m}.\end{aligned}$$

Comparison of (1.3) with (1.1) gives

$$(1.4)\qquad C_n^{(k)} = \sum_{m=0}^{[n/2]}\binom{k+n-1-m}{k-1}\binom{n-m}{m} \quad (k=1,2,\cdots).$$

For $k=1$, (1.4) reduces to a well-known identity for Fibonacci numbers.

Associated with the identity

$$(1.5)\qquad \delta_{nk} = \sum_{j=0}^{n-k}(-1)^j\binom{n-j}{j}\frac{k}{(2n-2j-k)}\binom{2n-2j-k}{n-j},$$

where δ_{nk} is the Kronecker delta, one has the inverse relations (see [3])

$$(1.6)\qquad a_n = \sum_{j=0}^{[n/2]}\binom{n-j}{j}b_{n-j}, \qquad b_n = \sum_{j=0}^{n}(-1)^j\frac{n-j}{n+j}\binom{n+j}{j}a_{n-j}.$$

An application of (1.6) with $a_n=C_n^{(k)}$ and $b_n=\binom{k+n-1}{k-1}$ gives the companion formula to (1.4) as

$$(1.7)\qquad \binom{k+n-1}{n} = \sum_{j=0}^{n}(-1)^j\frac{n-j}{n+j}\binom{n+j}{j}C_{n-j}^{(k)} \quad (k=1,2,\cdots).$$

For $k=1$, (1.7) gives

$$(1.8)\qquad 1 = \sum_{j=0}^{n}(-1)^j\frac{n-j}{n+j}\binom{n+j}{j}F_{n+1-j} \quad (n=0,1,\cdots).$$

One aim of this paper is to generalize (1.1) and the related identities, (1.2), (1.4), and (1.7), by replacing the Fibonacci sequence by a general linear recurring sequence of order two with real constant coefficients and arbitrary initial conditions. We will also obtain an explicit formula for these generalized kth convoluted numbers, which appear naturally in the evaluation of convoluted sums for linear recurring sequences of order two and higher.

2. A generalization of (1.1). The first generalization of (1.1) is given by

$$(2.1)\qquad (1-ax-bx^2)^{-k} = \sum_{n=0}^{\infty}C_n^{(k)}(a,b)x^n \quad (k=1,2,\cdots),$$

where a and $b\neq 0$ are real numbers. It should be noted that the numbers

$C_n^{(k)}(a, b)$ are not new, for they have appeared previously (but in a different notation) in the paper by Carlitz [4, p. 522]. Expanding (2.1) just as above on (1.3), we readily find that

$$(2.2)\quad C_n^{(k)}(a, b) = \sum_{m=0}^{[n/2]} b^m a^{n-2m} \binom{k+n-1-m}{k-1} \binom{n-m}{m} \quad (k = 1, 2, \cdots).$$

If we multiply both sides of (2.2) by $a^n b^{-n}$ and then apply (1.6) with

$$a_n = a^n b^{-n} C_n^{(k)}(a, b), \qquad b_n = a^{2n} b^{-n} \binom{k+n-1}{k-1},$$

we obtain, after simplification, the companion formula to (2.2) as

$$(2.3)\quad a^{2n} \binom{k+n-1}{n} = \sum_{j=0}^{n} (-1)^j \frac{n-j}{n+j} \binom{n+j}{j} a^{n-j} b^j C_{n-j}^{(k)}(a, b),$$

which gives (1.7) for $a = b = 1$.

We note that $C_n^{(k)}(a, b)$ and Gegenbauer polynomials, $P_n^{(k)}(t)$, are closely related. The generating function for the latter (see [5], pp. 81–85) is

$$(2.4)\quad (1 - 2tz + z^2)^{-k} = \sum_{n=0}^{\infty} P_n^{(k)}(t) z^n \quad (k = 1, 2, \cdots).$$

Hence

$$(2.5)\quad P_n^{(k)}(t) = \sum_{m=0}^{[n/2]} (-1)^m \binom{k+n-1-m}{k-1} \binom{n-m}{m} (2t)^{n-2m},$$

and

$$(2.6)\quad C_n^{(k)}(a, b) = b^{n/2} i^n P_n^{(k)}(-ia/(2\sqrt{b})) \quad (i^2 = -1;\ k = 1, 2, \cdots).$$

Since $C_n^{(k)} = C_n^{(k)}(1, 1) = i^n P_n^{(k)}(-i/2)$, the relations I and III in [1], p. 276 are instances of two well-known identities for Gegenbauer polynomials (see [5], p. 83, (4.7.17); p. 84, (4.7.27)).

If we multiply both sides of (2.5) by $(-1)^n (2t)^n$ and then apply (1.6) with

$$a_n = (-1)^n (2t)^n P_n^{(k)}(t), \qquad b_n = (-1)^n (2t)^{2n} \binom{k+n-1}{k-1},$$

we obtain the companion formula to (2.5),

$$(2.7)\quad (2t)^{2n} \binom{k+n-1}{n} = \sum_{j=0}^{n} \frac{n-j}{n+j} \binom{n+j}{j} (2t)^{n-j} P_{n-j}^{(k)}(t).$$

Identity (2.7) is of special interest, since $P_n^{(k)}(t)$, for $k = \frac{1}{2}, 1$, reduces, respectively, to Legendre polynomials and Chebyshev polynomials, $U_n(t)$, of the second kind. Since (see [5], p. 82, (4.7.8))

$$\lim_{k\to 0} k^{-1}\cdot P_m^{(k)}(t) = (2/m)T_m(t) \quad (m = 1, 2, \cdots), \tag{2.8}$$

where $T_m(t)$ is the Chebyshev polynomial of the first kind, and noting that

$$\binom{k+n-1}{n} = (k/n)\binom{k+n-1}{n-1},$$

we obtain from (2.7), upon using (2.8) with $m=n-j$, the identity

$$(2t)^{2n} = \sum_{j=0}^{n-1} \frac{2n}{n+j}\binom{n+j}{j}(2t)^{n-j}T_{n-j}(t) \quad (n = 1, 2, \cdots). \tag{2.9}$$

As already indicated, we obtain from (2.7) with $k=1$

$$(2t)^{2n} = \sum_{j=0}^{n-1} \frac{n-j}{n+j}\binom{n+j}{j}(2t)^{n-j}U_{n-j}(t) \quad (n = 1, 2, \cdots). \tag{2.10}$$

An application of (2.9) and (2.10) will be given in the next section.

Inverse relations (2.9) and (2.10) may be contrasted, respectively, to the following well-known inverse relations (see problem 4b of [6], Chapter 8, p. 223):

$$(2t)^n = 2\sum_{j=0}^{[n/2]}\binom{n}{j}T_{n-2j}(t) \quad (n = 1, 2, \cdots), \tag{2.11}$$

$$(2t)^n = \sum_{j=0}^{[n/2]}\left[\binom{n}{j} - \binom{n}{j-1}\right]U_{n-2j}(t) \quad (n = 1, 2, \cdots). \tag{2.12}$$

Inverse relation (2.7) may also be contrasted to the known result (see [7], p. 282 (32))

$$(1-t)^n 2^{-n-1} = n!(k+\tfrac{1}{2})_n \sum_{j=0}^{n}(-1)^j \frac{(k+j)}{(n-j)!(2k)_{n+j+1}} P_j^{(k)}(t), \tag{2.13}$$

where $(p)_n = p(p+1)\cdots(p+n-1)$.

3. A generalized k-th convoluted number for recurring sequences of order two. For complete generality, we recall from the theory of generating functions that if W_0, W_1, a, and $b\neq 0$ are real numbers, and if

$$W_{n+2} = aW_{n+1} + bW_n \quad (n = 0, 1, \cdots), \tag{3.1}$$

then for $k=1, 2, \cdots$, the identity

$$\begin{aligned}[W_0 + (W_1 - aW_0)x]^k(1 - ax - bx^2)^{-k} &= \left(\sum_{n=0}^{\infty} W_n x^n\right)^k \\ &= \sum_{n=0}^{\infty} A_n^{(k)}(a, b; W_0, W_1)x^n,\end{aligned} \tag{3.2}$$

defines the kth convoluted numbers $A_n^{(k)}(a, b; W_0, W_1) \equiv A_n^{(k)}$. Since $(1-ax-bx^2)\cdot(W(x))^k = [W_0+(W_1-aW_0)x](W(x))^{k-1}$, where $W(x) = W_0+W_1x+W_2x^2+\cdots$, the $A_n^{(k)}$ have the recurrence

$$(3.3)\quad A_n^{(k)} = aA_{n-1}^{(k)} + bA_{n-2}^{(k)} + W_0A_n^{(k-1)} + (W_1 - aW_0)A_{n-1}^{(k-1)} \quad (n, k = 2, 3, \cdots),$$

where $A_n^{(1)}(a, b; W_0, W_1) = W_n$, $n = 0, 1, \cdots$. We define the Lucas functions (of n) associated with (3.1) as Z_n and V_n, where $Z_n = A_n^{(1)}(a, b; 0, 1)$ and $V_n = A_n^{(1)}(a, b; 2, a)$, $n = 0, 1, \cdots$. Using (3.2), we note that $A_n^{(k)}(a, b; W_0, aW_0) = W_0^kC_n^{(k)}(a, b)$, $C_n^{(k)}(a, b) = A_n^{(k)}(a, b; 1, a)$, $n = 0, 1, \cdots$, and $A_n^{(k)}(a, b; 0, W_1) = W_1^kC_{n-k}^{(k)}(a, b)$, $n = k, k+1, \cdots$.

If we multiply both sides of (2.1) by $(W_0+(W_1-aW_0)x)^k$ and recall (3.2), we obtain the following result:

$$(3.4)\quad A_n^{(k)}(a, b; W_0, W_1) = \sum_{s=0}^{n} C_s^{(k)}(a, b)\binom{k}{n-s}(W_1 - aW_0)^{n-s}W_0^{s+k-n} \quad (n = 0, 1, \cdots).$$

If $k = 1$, we obtain from (3.4) the relations

$$(3.5)\quad Z_n = C_{n-1}^{(1)}(a, b) = \sum_{m=0}^{[(n-1)/2]} \binom{n-1-m}{m} b^m a^{n-1-2m} \quad (n = 1, 2, \cdots),$$

$$(3.6)\quad W_n = W_0C_n^{(1)}(a, b) + (W_1 - aW_0)C_{n-1}^{(1)}(a, b) \equiv W_0Z_{n+1} + (W_1 - aW_0)Z_n \quad (n = 1, 2, \cdots),$$

$$(3.7)\quad V_n = 2C_n^{(1)}(a, b) - aC_{n-1}^{(1)}(a, b) \equiv 2Z_{n+1} - aZ_n \quad (n = 1, 2, \cdots).$$

If we define

$$(3.8)\quad G_n(y) = \sum_{j=1}^{n} A_{n-j}^{(j)}(a, b; W_0, W_1)y^j \quad (n = 1, 2, \cdots),$$

then from (3.3), with $k = j$, both sides multiplied by y^j, and n replaced by $n+2-j$, we obtain by summation on j from 1 to $n+2$

$$(3.9)\quad G_{n+2}(y) = (a + W_0y)G_{n+1}(y) + [b + (W_1 - aW_0)y]G_n(y) \quad (n = 1, 2, \cdots),$$

where $G_1(y) = W_0y$ and $G_2(y) = W_1y+W_0^2y^2$. If we define

$$(3.10)\quad G(x, y) = \sum_{n=0}^{\infty} G_{n+1}(y)x^n,$$

then, from (3.2) with $k = 1$, we obtain the generating function

$$(3.11)\quad G(x, y) = y[W_0+(W_1-aW_0)x]/[1-(a+W_0y)x-(b+(W_1-aW_0)y)x^2];$$

and if $w = W_1/W_0$, $W_0 \neq 0$, then

$$G(x(a+y)^{-1}, yW_0^{-1}) = y[1+(w-a)(a+y)^{-1}x] \\ /[1-x-(b+wy-ay)(a+y)^{-2}x^2] \\ = y[1+(w-a)(a+y)^{-1}x]K(x,(b+wy-ay)(a+y)^{-2}), \tag{3.12}$$

where

$$K(x,u) = (1-x-ux^2)^{-1} = \sum_{n=0}^{\infty} K_n(u)x^n. \tag{3.13}$$

Thus, from (3.12), with $z=(b+wy-ay)(a+y)^{-2}$, we obtain

$$G_{n+1}(y/W_0) = y(a+y)^n[K_n(z)+(w-a)(a+y)^{-1}K_{n-1}(z)] \quad (n=0,1,\cdots). \tag{3.14}$$

Since $K_n(u)=C_n^{(1)}(1,u)$, we obtain from (2.2) that

$$K_n(u) = \sum_{m=0}^{[n/2]} \binom{n-m}{m} u^m \quad (n=0,1,\cdots), \tag{3.15}$$

and (3.15) can be used in (3.14) to obtain $G_{n+1}(y)$ as a sum. We note that

$$(1-ax-bx^2)^{-1} = K(ax, b/a^2). \tag{3.16}$$

For $h=\sqrt{1+4u}$, we have the known identity

$$K_n(u) = \begin{cases} 2^{-n-1}h^{-1}[(1+h)^{n+1}-(1-h)^{n+1}], & h \neq 0; \\ 2^{-n}(n+1), & h=0, \end{cases} \tag{3.17}$$

(see problem 5b of [6], Chapter 8). Substitution of (3.17) with $u=z$ into (3.14) gives $G_{n+1}(y)$ explicitly.

If $W_1=aW_0$, then $w=a$, and (3.14), with $g_{n+1}(y)\equiv G_{n+1}(y/W_0)$ reduces to

$$g_{n+1}(y) = y(a+y)^n K_n(b/(a+y)^2) = \sum_{j=1}^{n+1} C_{n+1-j}^{(j)}(a,b)y^j \quad (n=0,1,\cdots). \tag{3.18}$$

If $a=b=y=1$, then (3.18), using (3.17) with $h=\sqrt{2}$, gives relation IV in [1]. Using (3.15), we obtain from (3.18)

$$g_{n+1}(y) = y\sum_{m=0}^{[n/2]} \binom{n-m}{m} b^m(a+y)^{n-2m} \quad (n=0,1,\cdots). \tag{3.19}$$

An interesting example of (3.18) occurs when $b<0$ and $b/(a+y)^2=-\frac{1}{4}$. Let $b=-p^2$, $p>0$. Choosing $a+y=2p$, we obtain from (3.18) (since $h=0$) the identity

$$\sum_{j=1}^{n+1} (2p-a)^{j-1}\cdot C_{n+1-j}^{(j)}(a,-p^2) = (n+1)p^n \quad (p>0;\ n=0,1,\cdots). \tag{3.20}$$

We note that the right-hand side of (3.20) is independent of a. Since (see (2.2))

$$(3.21)\quad C_{2n+1}^{(k)}(0, b) = 0, \qquad C_{2n}^{(k)}(0, b) = b^n \binom{n + k - 1}{n} \quad (n = 0, 1, \cdots),$$

we obtain from (3.20) with $a=0$ the following identities for $n=2m+1$ and $n=2m$, respectively:

$$(3.22)\quad \sum_{r=1}^{m+1} (-1)^{m+1-r} \binom{m + r}{2r - 1} 4^r = 4m + 4 \quad (m = 0, 1, \cdots),$$

$$(3.23)\quad \sum_{r=1}^{m+1} (-1)^{m+1-r} \binom{m + r - 1}{2r - 2} 4^r = 8m + 4 \quad (m = 0, 1, \cdots).$$

Since $P_n^{(k)}(y) = (-1)^n P_n^{(k)}(-y)$ (see (2.5)), we obtain from (2.6) that $C_n^{(k)}(2x, -1) = P_n^{(k)}(x)$. Thus, from (3.20) with $a=2x$ and $p=1$, we obtain an identity for Gegenbauer polynomials,

$$(3.24)\quad \sum_{j=1}^{n+1} (2 - 2x)^{j-1} P_{n+1-j}^{(j)}(x) = n + 1 \quad (n = 0, 1, \cdots).$$

If we multiply both sides of (3.19) by $(a+y)^n b^{-n}$ and then apply (1.6) with

$$a_n = (a + y)^n b^{-n} g_{n+1}(y) \quad \text{and} \quad b_n = y b^{-n} (a + y)^{2n},$$

we obtain the following companion formula to (3.19):

$$(3.25)\quad y(a + y)^{2n} = \sum_{j=0}^{n} (-1)^j \frac{n - j}{n + j} \binom{n + j}{j} b^j (a + y)^{n-j} g_{n+1-j}(y).$$

It is of interest to note that the Lucas functions, V_n and Z_n, associated with (3.1) can be expressed in terms of Chebyshev polynomials as follows:

$$(3.26)\quad V_n = 2(-b)^{n/2} T_n(a/(2i\sqrt{b})) \qquad (n = 0, 1, \cdots),$$

$$(3.27)\quad Z_{n+1} = (-b)^{n/2} U_n(a/(2i\sqrt{b})) \qquad (n = 0, 1, \cdots).$$

To prove (3.26), set $x=a/(2i\sqrt{b})$ in the identity $T_{n+2}(x) = 2xT_{n+1}(x) - T_n(x)$, and then multiply both sides by $2(-b)^{(n+2)/2}$. Thus, using (3.26), we have $V_0=2$, $V_1=a$, and $V_{n+2}=aV_{n+1}+bV_n$, $n=0, 1, \cdots$. A similar proof using $U_n(x)$ can also be given for (3.27).

If we set $t=a/(2i\sqrt{b})$ in (2.9) and (2.10) and then simplify by using (3.26) and (3.27), we obtain, respectively,

$$(3.28)\quad a^{2n} = \sum_{j=0}^{n-1} (-1)^j \frac{n}{n + j} \binom{n + j}{j} a^{n-j} b^j V_{n-j} \qquad (n = 1, 2, \cdots),$$

$$(3.29)\quad a^{2n} = \sum_{j=0}^{n-1} (-1)^j \frac{n - j}{n + j} \binom{n + j}{j} a^{n-j} b^j Z_{n+1-j} \quad (n = 1, 2, \cdots).$$

The companion formula to (3.29) is given by (3.5).

If $a=b=1$, then (3.1) defines the Fibonacci sequence with $Z_n \equiv F_n$ and $V_n \equiv L_n$, the Lucas sequence. Thus, from (3.28), we obtain the identity

$$1 = \sum_{j=0}^{n-1} (-1)^j \frac{n}{n+j}\binom{n+j}{j} L_{n-j} \quad (n = 1, 2, \cdots); \tag{3.30}$$

and from (3.29) we obtain a previous result, (1.8).

If $a=2$ and $b=-1$, then (3.1) defines sequences where $Z_n \equiv n$ and $V_n \equiv 2$. Thus, from (3.28) and (3.29), we obtain, respectively,

$$2^{2n-1} = \sum_{j=0}^{n-1} \frac{n}{n+j}\binom{n+j}{j} 2^{n-j}, \tag{3.31}$$

$$2^{2n} = \sum_{j=0}^{n-1} \frac{n-j}{n+j}\binom{n+j}{j} 2^{n-j}(n+1-j). \tag{3.32}$$

From (3.5), we obtain

$$n = \sum_{m=0}^{[(n-1)/2]} (-1)^m 2^{n-1-2m}\binom{n-1-m}{m}. \tag{3.33}$$

Moreover, since

$$(1-x)^{-2k} = \sum_{n=0}^{\infty}\binom{2k+n-1}{n} x^n,$$

we have

$$C_n^{(k)}(2, -1) = \binom{2k+n-1}{n}$$

(see (2.1)). Thus, from (2.3), we obtain the identity

$$2^{2n}\binom{k+n-1}{n} = \sum_{j=0}^{n} \frac{n-j}{n+j}\binom{n+j}{j}\binom{2k+n-j-1}{n-j} 2^{n-j}. \tag{3.34}$$

4. Evaluation of convoluted sums for recurring sequences of order three. Let Q_1, Q_2, m_1, m_2, and $m_3 \neq 0$ be real numbers and let Q_n, with $Q_0 = 0$, satisfy

$$Q_{n+3} + m_1 Q_{n+2} + m_2 Q_{n+1} + m_3 Q_n = 0 \quad (n = 0, 1, \cdots). \tag{4.1}$$

The generating function of Q_n is given by

$$\sum_{n=0}^{\infty} Q_n x^n = x(Q_1 + (Q_2 + m_1 Q_1)x)/(1 + m_1 x + m_2 x^2 + m_3 x^3). \tag{4.2}$$

Let $f(x) \equiv 1 + m_1 x + m_2 x^2 + m_3 x^3 = (1 - rx)(1 - ax - bx^2)$, where $r^{-1} \neq 0$ is a real root of $f(x) = 0$. Then $m_1 = -a - r$, $m_2 = ar - b$, and $m_3 = br$; and thus $b = m_3/r$

and $a=-m_1-r$. Recalling that

$$(1-x)^{-k}=\sum_{j=0}^{\infty}\binom{k-1+j}{k-1}x^j,$$

we obtain from (4.2), with $W_0=Q_1$ and $W_1-aW_0=Q_2+m_1Q_1$,

$$\begin{aligned}\left(\sum_{n=0}^{\infty}Q_nx^n\right)^k&=\left(\frac{x}{1-rx}\right)^k\left(\frac{W_0+(W_1-aW_0)x}{1-ax-bx^2}\right)^k\\&=\sum_{n=k}^{\infty}r^{n-k}\binom{n-1}{k-1}x^n\sum_{j=0}^{\infty}A_j^{(k)}(a,b;W_0,W_1)x^j\\&=\sum_{n=k}^{\infty}\left(\sum_{j=0}^{n-k}r^{n-j-k}\binom{n-j-1}{k-1}A_j^{(k)}(a,b;W_0,W_1)\right)x^n.\end{aligned}\tag{4.3}$$

Thus, from (4.3), we obtain an identity for the kth convoluted sum (or number) for a recurring sequence Q_n of order three, namely,

$$\begin{aligned}&\sum_{j=0}^{n-k}r^{n-k-j}\binom{n-1-j}{k-1}A_j^{(k)}(-m_1-r,m_3/r;Q_1,Q_2-rQ_1)\\&\qquad=\sum_{i_1+i_2+\cdots+i_k=n}Q_{i_1}Q_{i_2}\cdots Q_{i_k}\quad(n\geqq k).\end{aligned}\tag{4.4}$$

We note that the left-hand side of (4.4) is a linear combination of kth convoluted numbers generated by a recurring sequence of order two.

As an example of (4.4), it is readily verified that $Q_n=Z_nZ_{n+1}$, $n=0,1,\cdots$, satisfies (4.1) with $m_1=-b-a^2$, $m_2=-ba^2-b^2$, and $m_3=b^3$. Since $Q_1=a$ and $Q_2=a^3+ab$, we have $Q_2+m_1Q_1=0$. Thus, from (4.2) we obtain the generating function

$$\sum_{n=0}^{\infty}Z_nZ_{n+1}x^n=\frac{x}{1+bx}\cdot\frac{a}{1-(a^2+2b)x+b^2x^2}.\tag{4.5}$$

Since $r=-b$, we have $-m_1-r=a^2+2b$, $m_3/r=-b^2$, $Q_2-rQ_1=a^3+2ab$, and so $Q_2-rQ_1=(-m_1-r)Q_1$. We obtain from (4.4) the identity

$$\begin{aligned}&a^k\sum_{j=0}^{n-k}(-b)^{n-k-j}\binom{n-1-j}{k-1}C_j^{(k)}(a^2+2b,-b^2)\\&\qquad=\sum_{i_1+i_2+\cdots+i_k=n}\prod_{s=1}^{k}Z_{i_s}Z_{1+i_s}\quad(n\geqq k).\end{aligned}\tag{4.6}$$

For the special case $a=2$ and $b=-1$, we have, as before,

$$Z_n\equiv n\quad\text{and}\quad C_j^{(k)}(2,-1)=\binom{2k+j-1}{j}.$$

Thus, from (4.6), we obtain the identity

$$(4.7)\quad 2^k \sum_{j=0}^{n-k} \binom{n-1-j}{k-1}\binom{2k+j-1}{j} = \sum_{i_1+i_2+\cdots+i_k=n} \prod_{s=1}^{k} i_s(1+i_s) \quad (n \geqq k).$$

Since $C_0^{(k)}(x, y)=1$ and $C_1^{(k)}(x, y)=xk$, then (4.6), with $k=n-1$, gives the identity

$$(4.8)\quad a^{n-1}(a^2+b)(n-1) = \sum_{i_1+i_2+\cdots+i_{n-1}=n} \prod_{s=1}^{n-1} Z_{i_s}Z_{1+i_s} \quad (n=2, 3, \cdots).$$

An identity for Chebyshev polynomials can be obtained from (4.8), for when $a=2x$ and $b=-1$, we have $Z_n \equiv U_{n-1}(x)$, $n=0, 1, \cdots$.

REMARKS. The above method may be used to evaluate convoluted sums for recurring sequences of order four and higher. As an example, we note that $R_n=F_nF_{n+1}F_{n+2}$ or $F_{n+1}^2F_{n+2}$ satisfies $R_{n+4}-3R_{n+3}-6R_{n+2}+3R_{n+1}+R_n=0$ for $n=0, 1, \cdots$. Thus, we have the following generating functions:

$$(4.9)\quad \sum_{n=0}^{\infty} F_nF_{n+1}F_{n+2}x^n = \frac{2x}{1-3x-6x^2+3x^3+x^4} = \frac{2x}{1+x-x^2}\cdot\frac{1}{1-4x-x^2},$$

$$(4.10)\quad \sum_{n=0}^{\infty} F_{n+1}^2F_{n+2}x^n = \frac{1-x}{1+x-x^2}\cdot\frac{1}{1-4x-x^2}.$$

Recalling (2.1), and (3.2) we obtain from (4.9)

$$(4.11)\quad \left(\sum_{n=0}^{\infty} F_nF_{n+1}F_{n+2}x^n\right)^k = \sum_{n=0}^{\infty} A_n^{(k)}(-1, 1; 0, 2)x^n \sum_{j=0}^{\infty} C_j^{(k)}(4, 1)x^j,$$

and from (4.11) the identity for $n \geqq k$,

$$(4.12)\quad 2^k \sum_{j=k}^{n} C_{n-j}^{(k)}(4, 1)C_{j-k}^{(k)}(-1, 1) = \sum_{i_1+i_2+\cdots+i_k=n} \prod_{s=1}^{k} F_{i_s}F_{1+i_s}F_{2+i_s}.$$

Using (2.1) and (3.2), we obtain from (4.10)

$$(4.13)\quad \left(\sum_{n=0}^{\infty} F_{n+1}^2F_{n+2}x^n\right)^k = \sum_{j=0}^{\infty} A_j^{(k)}(-1, 1; 1, -2)x^j \sum_{n=0}^{\infty} C_n^{(k)}(4, 1)x^n;$$

and from (4.13), we obtain the identity

$$(4.14)\quad \sum_{j=0}^{n} A_j^{(k)}(-1, 1; 1, -2)C_{n-j}^{(k)}(4, 1) = \sum_{i_1+i_2+\cdots+i_k=n} \prod_{s=1}^{k} F_{1+i_s}^2F_{2+i_s}.$$

5. Additional convoluted sums. Since

$$(1-ax-bx^2)^{-1} = \sum_{j=0}^{\infty} Z_jx^{j-1},$$

we obtain after one differentiation (for $k=1$)

$$\left(\sum_{n=0}^{\infty}(n+1)Z_{n+2}x^n\right)^k = \left(\frac{a+2bx}{(1-ax-bx^2)^2}\right)^k$$

$$= (1-ax-bx^2)^{-k}\cdot\left(\frac{a+2bx}{(1-ax-bx^2)}\right)^k \tag{5.1}$$

$$= \sum_{j=0}^{\infty} C_j^{(k)}(a,b)x^j \sum_{n=0}^{\infty} A_n^{(k)}(a,b;a,a^2+2b)x^n,$$

and from (5.1) we obtain the identity

$$\sum_{j=0}^{n} C_{n-j}^{(k)}(a,b)A_j^{(k)}(a,b;a,a^2+2b) = \sum_{i_1+i_2+\cdots+i_k=n}\ \prod_{s=1}^{k}(1+i_s)Z_{2+i_s}. \tag{5.2}$$

For $a=2$ and $b=-1$,

$$A_n^{(k)}(2,-1;2,2) = 2^k\binom{k-1+n}{k-1},$$

and thus (5.2) gives

$$2^k\sum_{j=0}^{n}\binom{2k+n-1-j}{2k-1}\binom{k-1+j}{k-1} = \sum_{i_1+i_2+\cdots+i_k=n}\ \prod_{s=1}^{k}(1+i_s)(2+i_s). \tag{5.3}$$

For $a=2x$ and $b=-1$, (5.2) gives an identity for Gegenbauer polynomials,

$$\sum_{j=0}^{n} P_{n-j}^{(k)}(x)A_j^{(k)}(2x,-1;2x,4x^2-2) = \sum_{i_1+i_2+\cdots+i_k=n}\ \prod_{s=1}^{k}(1+i_s)U_{1+i_s}(x). \tag{5.4}$$

For $k=1$, (5.4) simplifies to

$$2\sum_{j=0}^{n} U_{n-j}(x)T_{j+1}(x) = (n+1)U_{n+1}(x). \tag{5.5}$$

Recalling (3.26) and (3.27), we obtain from (5.5) for $x=a/(2i\sqrt{b})$ the identity

$$(n+1)Z_{n+2} = \sum_{j=0}^{n} Z_{n+1-j}V_{j+1} \tag{5.6}$$

for the Lucas functions associated with (3.1).

For $W_n\equiv Z_n$, (3.1) is of special interest when $b=-c^2$, $c\neq 0$. Since $x/(1-ax+c^2x^2)=\sum_{n=0}^{\infty}Z_nx^n$, we obtain after one differentiation (for $k=1$)

$$\left(\sum_{n=0}^{\infty}(n+1)Z_{n+1}x^n\right)^k = \left(\frac{1+cx}{1-ax+c^2x^2}\right)^k\left(\frac{1-cx}{1-ax+c^2x^2}\right)^k, \tag{5.7}$$

and from (5.7) we obtain the identity

$$\sum_{j=0}^{n} A_j^{(k)}(a, -c^2; 1, a+c)A_{n-j}^{(k)}(a, -c^2; 1, a-c) = \sum_{i_1+i_2+\cdots+i_k=n} \prod_{s=1}^{k} (1+i_s)Z_{1+i_s}. \tag{5.8}$$

If $a=2$, $c=1$, then $Z_n \equiv n$, with

$$\sum_{n=0}^{\infty} A_n^{(k)}(2, -1; 1, 1)x^n = (1-x)^{-k} = \sum_{j=0}^{\infty} \binom{k-1+j}{j} x^j,$$

and

$$\sum_{j=0}^{\infty} A_j^{(k)}(2, -1; 1, 3)x^j = (1+x)^k(1-x)^{-2k} = \sum_{j=0}^{\infty} \left(\sum_{s=0}^{j} \binom{k}{j-s} \binom{2k-1+s}{s} \right) x^j.$$

Thus, from (5.8), we obtain the identity

$$\sum_{j=0}^{n} \binom{n+k-1-j}{k-1} \sum_{s=0}^{j} \binom{k}{j-s} \binom{2k-1+s}{s} = \sum_{i_1+i_2+\cdots+i_k=n} \prod_{s=1}^{k} (1+i_s)^2. \tag{5.9}$$

Added in proof. Additional simplification of (4.7) and (5.3) occurs by noting, respectively, that

$$\sum_{j=0}^{n-k} \binom{n-1-j}{k-1} \binom{2k+j-1}{j} = \binom{2k+n-1}{n-k}, \tag{6.1}$$

$$\sum_{j=0}^{n} \binom{2k+n-1-j}{2k-1} \binom{k-1+j}{k-1} = \binom{3k+n-1}{n}. \tag{6.2}$$

Acknowledgment. I wish to thank the referee for his constructive review of my paper, and especially for his suggestion of (1.6), which appears to have many interesting applications.

THE GROUP OF AUTOMORPHISMS OF THE GAME OF 3-DIMENSIONAL TICKTACKTOE

ROLAND SILVER, MITRE Corporation

1. The automorphisms of a board-game. The player of the ordinary game of Ticktacktoe recognizes intuitively that an initial play in the upper-left hand corner square is essentially the same as an initial play in any other corner. He also will admit that the following eight positions are essentially the same, all consisting of "an X in a corner square, and an O in an adjacent side square."

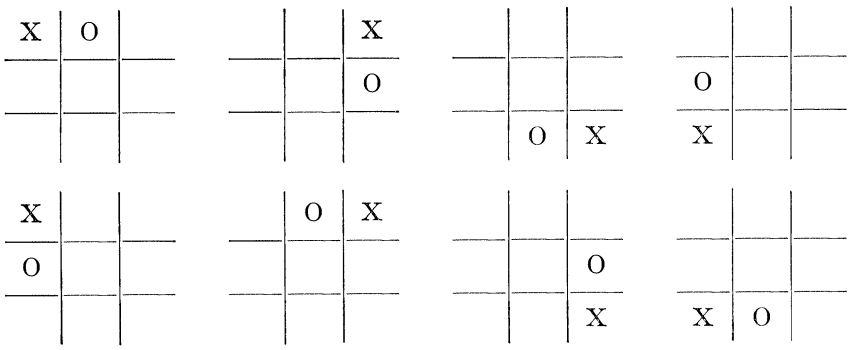

FIG. 1. Equivalent positions.

After some thought, he will probably agree that no other position is essentially the same as one of these.

Behind this notion of the "essential sameness" of two positions P_1 and P_2 is a formal idea: There is a one-one mapping F of the board (the set of squares) onto itself, such that:

(1) $P_2 = P_1F$ (P_2 is the image of P_1 under the mapping F).

(2) For any sequence of legal moves $m_1 \cdot \cdot \cdot m_k$ made starting from position P_1 and leading to position P_3, the corresponding sequence of moves $m_1F \cdot \cdot \cdot m_kF$ are legal starting from position P_2 and lead to position P_3F.

(3) P_3 is won for X, won for O, drawn, or undecided, according as P_3F is won for X, won for O, drawn, or undecided, respectively.

Looking at it another way, if a player has a strategy for playing from position P_1, the transformation F gives him a recipe for transforming that strategy into one for playing from position P_1F. The essential property that F possesses is that it *preserves 3 in a row*: Three distinct points a, b, c of the board are collinear if and only if aF, bF, cF are collinear. An *automorphism* of Ticktacktoe is a mapping of the board onto itself that preserves 3 in a row.

The set $\overline{T}_2$ of mappings of the Ticktacktoe board onto itself is a set of 9! elements. Given U, V in $\overline{T}_2$, we define the *product* UV to be the mapping which takes a square s of the board into the square $(sU)V$. The set $\overline{T}_2$ forms a group

under this product operation; in fact it is isomorphic to S_9, the symmetric group on 9 elements.

The set of automorphisms $\overline{A}_2$ of the game is a subgroup of $\overline{T}_2$; in fact it is just the group of symmetries (rotations and reflections) of the square, having 8 elements. The elements of $\overline{A}_2$ map the position P into the 8 positions shown in Figure 1, which perhaps makes clearer why these 8 positions and only these are equivalent to P.

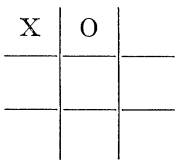

FIG. 2. A position.

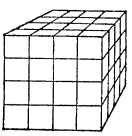

FIG. 3.

2. The board and rules of 3 DT (3-dimensional Ticktacktoe). 3 DT (3-Dimensional Ticktacktoe) is played by two players on a board consisting of 64 unit cubes (*cells*) stacked into a larger $4\times4\times4$ cube. The first player chooses any cell of the board, and places his mark ("X") in it. The second player then chooses any other cell, and places his mark ("O") in it. The game proceeds as the players alternate marking previously unmarked cells, until one of two things happens:

(1) The mover wins by making a cell which creates four-in-a-row, i.e., there are 4 cells, all marked by him, whose centers are collinear.

(2) The board is completely filled, but neither player has 4-in-a-row, constituting a tie.

Just as in Ticktacktoe, there are one-one mappings of the 3DT board which preserve the "essential sameness" of positions. We will define these automorphisms, and show that they form a group of 192 elements. This group will be seen to contain some peculiar mappings which scramble the cells of the board while preserving 4-in-a-row.

3. Points and lines of 3DT. We choose a coordinate system in which the center of each board cell has integer coordinates 0, 1, 2, or 3. We will refer to a triple (x, y, z) with $0\leqq x\leqq3$, $0\leqq y\leqq3$, $0\leqq z\leqq3$ as a *point* of the board. For clarity

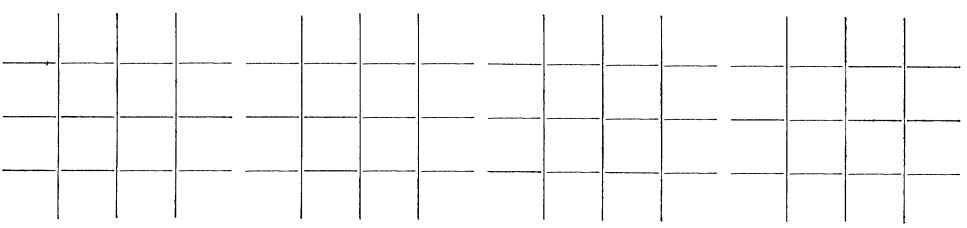

FIG. 4. A representation of the 3DT board.

we shall depict the board as four 4×4 squares representing the cross-sections $Z=0$, $Z=1$, $Z=2$, $Z=3$, from left to right.

We partition the 64 points of the board into two classes: *rich* points and *poor* points. The 16 rich points are marked "r" in the following diagram; the other 48 points are poor. A point (x, y, z) is *rich* if each of x, y, and z is 0 or 3, or if each of x, y, and z is 1 or 2; otherwise it is poor.

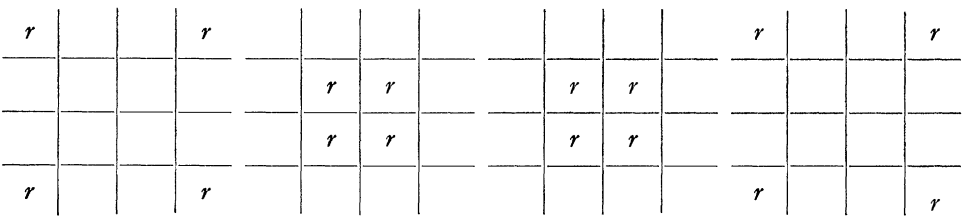

FIG. 5. The 16 rich points.

A *line* is a set of four distinct points of the board which lie in a straight line in the 3-dimensional space in which the points of the board are embedded. We will speak of a point being *on* a line, and of two lines *intersecting* in a point, in the usual sense. Two or more distinct points $p_1, \cdots, p_n$ are *collinear* if they all lie on some line. There are just 76 lines, which we divide into four classes:

3.1. *Full lines*—A *full* line consists of four rich points. There are 4 full lines: the "space" diagonals (see the line marked "f" in Figure 6).

3.2. *Empty lines*—An *empty* line consists of 4 poor points. There are 24 empty lines: the lines parallel to the coordinate axes which do not pass through rich points (see the lines marked "e_1," and "e_2" in Figure 6).

3.3. *Diagonal line*—A *diagonal* line consists of 2 rich and 2 poor points, and passes through two opposite edges of the cube. There are 24 diagonal lines (see the lines marked "d_1" and "d_2" in Figure 6).

3.4. *Ranking lines*—A *ranking* line consists of 2 rich and 2 poor points and is parallel to a coordinate axis. There are 24 ranking lines (see the line marked "r_1" and "r_2" in Figure 6).

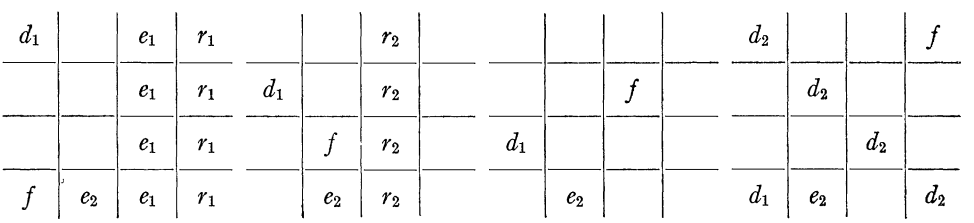

FIG. 6. Examples of the four classes of lines.

We note some interesting properties of these classifications:

3.5. Each rich point lies on 7 lines: 1 rich, 3 diagonal, and 3 ranking.

3.6. Each poor point lies on 4 lines: 2 poor, 1 diagonal, and 1 ranking.

Let us define the *star* of a line L to be the set of all points not on L, but collinear with some point on L.

3.7. Each diagonal line has 34 points in its star (see Figure 7).

3.8. Each ranking line has 36 points in its star (see Figure 8).

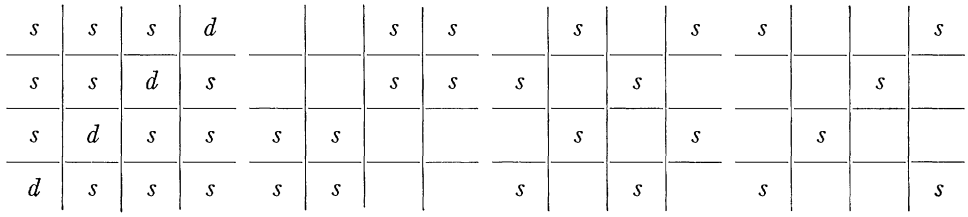

FIG. 7. The star of a diagonal line.

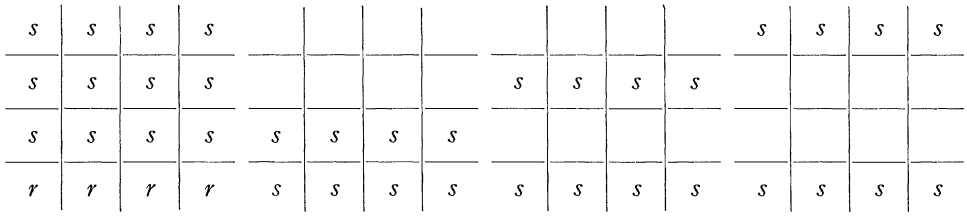

FIG. 8. The star of a ranking line.

4. Automorphisms of 3DT; Invariants. The set $\overline{T}_3$ of all one-one mappings of the 3DT board onto itself has 64! elements. Given a mapping $T \in \overline{T}_3$ and a line $L = \{p_1, p_2, p_3, p_4\}$, we define LT to be $\{p_1T, p_2T, p_3T, p_4T\}$. Given U, V in $\overline{T}_3$, we define the *product* UV to be the mapping: $p \to (pU)V$. Under this product operation, the set $\overline{T}_3$ forms a group isomorphic to S_{64}, the symmetric group on 64 elements.

An *automorphism* A of 3DT is a member of $\overline{T}_3$ which preserves lines, that is, for any line $\{p_1, p_2, p_3, p_4\}$, the four points p_1A, p_2A, p_3A, p_4A are collinear. Let $\overline{A}_3$ be the set of automorphisms of $\overline{T}_3$.

4.1. It is obvious that the product of any two automorphisms is an automorphism. It follows that $\overline{A}_3$ is a group.

4.2. For any automorphism A, A^{-1} is an automorphism, so that p_1, p_2, p_3, p_4 are collinear if and only if p_1A, p_2A, p_3A, p_4A are. Clearly an automorphism maps distinct lines into distinct lines. A set of points $\overline{P}$ is *invariant* if for any A in $\overline{A}_3$, p in $\overline{P}$ implies pA in $\overline{P}$.

A set of lines $\overline{L}$ is *invariant* if for any $A \in \overline{A}_3$, $L \in \overline{L}$ implies LA in $\overline{L}$.

4.3. It is clear that the following sets are invariant: rich points (by 3.5), poor points (by 3.6), full lines (by 3.1), empty lines (by 3.2), diagonal lines (by 3.7), ranking lines (by 3.8).

These classifications will be useful further on in proving that we have caught all the members of $\bar{A}_3$. It will turn out that the points and lines cannot be parti-

tioned more finely than we have done, in the sense that none of the six sets of 4.3 contains an invariant proper subset. In fact, $\overline{A}_3$ will turn out to be transitive over each of these sets.

5. The group $\overline{R}$ of rotations of the 3DT board. There are 24 rotations which carry the cube into itself:

5.1. The identity.

5.2. Rotation by 90°, 180°, 270° about each of three axes through the centers of opposite faces of the cube.

5.3. Rotation by 180° about each of six axes bisecting opposite edges of the cube.

5.4. Rotation by 120° and 240° about each of 4 axes through opposite corners of the cube.

These 24 rotations form a subgroup $\overline{R}$ of $\overline{T}_3$. They are obviously automorphisms.

6. The evisceration mapping E and the scramble mapping S. Consider the mapping E: $(x, y, z)\rightarrow(xe, ye, ze)$ where $0e=1$, $1e=0$, $2e=3$, $3e=2$. The mapping E turns the board inside out, mapping the 8 interior rich points onto the 8 exterior rich points, and *vice versa*.

Also, consider S: $(x, y, z)\rightarrow(xs, ys, zs)$, where $0S=0$, $1S=2$, $2S=1$, $3S=3$. S scrambles the interior rich points, mapping each into its opposite, while leaving the 8 exterior rich points fixed.

It is not too hard to see that both E and S are automorphisms.

7. The "flexible" group $\overline{F}$ of the 3DT board. Consider e and s as permutations on the set $\{0, 1, 2, 3\}$. Letting "i" denote the identity element, we have

$$\begin{aligned} e &= (01)(23) & e^2 &= i \\ s &= (12) & s^2 &= i \\ es &= (0231) \\ se &= (0132) \\ ese &= (03) \\ ses &= (03)(12) \\ eses &= sese = (03)(12). \end{aligned}$$

Thus s and e generate the 8 element group $\{i, e, s, es, se, ese, ses, eses\}$. In an analogous way, S and E generate the 8 element group $\overline{F}=\{I, E, S, ES, SE, ESE, SES, ESES\}$, which is evidently a subgroup of $\overline{A}_3$. For example

$$(x, y, z)ESE = (xe, ye, ze)SE = (xes, yes, zes)E = (xese, yese, zese).$$

In fact, $\overline{F}$ is isomorphic to the group of symmetries of the square!

8. The group $\overline{R}\times\overline{F}$. The set $\overline{R}\overline{F}$ of all elements of the form RF, with R in $\overline{R}$ and F in $\overline{F}$ is a direct product if

(1) $\overline{R}\cap\overline{F}=\{I\}$, and (2) $\overline{R}$ and $\overline{F}$ commute.

8.1. It is obvious that no member of $\overline{F}$ except I is a rotation.

8.2. Let us define a to be $ses = (03)(12)$, and define the following mappings in $\overline{T}_3$:

$$(x, y, z)T_x = (xa, y, z) \qquad (x, y, z)T_{xy} = (y, x, z)$$

$$(x, y, z)T_y = (x, ya, z) \qquad (x, y, z)T_{yz} = (x, z, y)$$

$$(x, y, z)T_z = (x, y, za) \qquad (x, y, z)T_{xz} = (z, y, x).$$

Every rotation in R can be expressed as a product of some of these 6 elements. To show that $\overline{R}$ and $\overline{F}$ commute, it will suffice then to show that each of these six elements commutes with E and with S.

- We have $ae = esese = eeses = ea$, and $as = esess = seses = sa$. Now:

$$(x, y, z)T_xE = (xae, ye, ze) = (xea, ye, ze) = (x, y, z)ET_x; \quad \text{so } T_xE = ET_x.$$

$(x, y, z)T_{xy}E = (y, x, z)E = (ye, xe, ze) = (xe, ye, ze)T_{xy} = (x, y, z)ET_{xy}$, so $T_{xy}E = ET_{xy}$. The other 10 commutation relations are demonstrated similarly. We have thus that the product $\overline{RF}$ is in fact a direct product.

This group $\overline{R}\times\overline{F}$ is a subgroup of $\overline{A}_3$ containing $24\times 8 = 192$ elements.

9. Completeness of $\overline{R}\times\overline{F}$. We want to show that in fact $\overline{R}\times\overline{F} = \overline{A}_3$. This will follow if we can show two things:

9.1. Given any automorphism A, there is an X in $\overline{R}\times\overline{F}$ such that AX leaves the four points (0, 0, 0), (1, 0, 0), (3, 0, 0), (0, 3, 0) fixed.

9.2. If an automorphism A leaves the four points (0, 0, 0), (1, 0, 0), (3, 0, 0), (0, 3, 0) fixed, then $A = I$.

Let us proceed: $P = (0, 0, 0)A$ is a rich point. If p is an interior point, then let $X_1 = E$, otherwise let $X_1 = I$. Thus, pX_1 is an exterior rich point. There is some rotation X_2 which takes pX_1 into (0, 0, 0), so (0, 0, 0) is fixed under AX_1X_2.

Now consider the line L through (0, 0, 0) and (3, 0, 0). L is a ranking line, so LAX_1X_2 is a ranking line L' through (0, 0, 0). There is clearly a rotation X_3 which leaves (0, 0, 0) fixed, and for which $L'X_3 = L$. Thus $AX_1X_2X_3$ fixes (0, 0, 0) and maps L into L. Since (3, 0, 0) is the other rich point on L, $AX_1X_2X_3$ fixes (3, 0, 0). $AX_1X_2X_3$ takes the ranking line through (0, 0, 0) and (0, 3, 0) into either the ranking line through (0, 0, 0) and (0, 3, 0) or the ranking line through (0, 0, 0) and (0, 0, 3). In the former case, let $X_4 = I$. In the latter case, consider the mapping R: $(x, y, z)R = (xa, za, ya)$. R is clearly the rotation about the bisectors of the edges $\{(0, 0, 3), (3, 0, 3)\}$ and $\{(0, 3, 0), (3, 3, 0)\}$. Let $X_4 = RESES$. Thus X_4 is in $\overline{R}\times\overline{F}$.

We have $(0, 0, 0)X_4 = (0, 0, 0)$, $(3, 0, 0)X_4 = (3, 0, 0)$, $(0, 0, 3)X_4 = (0, 3, 0)$. Thus X_4 leaves (0, 0, 0) and (3, 0, 0) fixed, and maps $(0, 3, 0)AX_1X_2X_3$ into (0, 3, 0). Therefore $AX_1X_2X_3X_4$ leaves the three points (0, 0, 0), (3, 0, 0) and (0, 3, 0) fixed. Now $(1, 0, 0)AX_1X_2X_3X_4$ is a poor point on the line through (0, 0, 0) and (3, 0, 0), hence it is either (1, 0, 0) or (2, 0, 0). Let $X_5 = I$ or S accordingly. Both S and I leave (0, 0, 0), (3, 0, 0) and (0, 3, 0) fixed.

Thus, $AX_1X_2X_3X_4X_5$ leaves the four points fixed. Letting $X = X_1X_2X_3X_4X_5$, we have proven 9.1.

Let A be an automorphism. We have evidently:

9.3. If A fixes three points on a line, then it fixes the fourth also.

9.4. If A leaves a diagonal (ranking) line invariant, and fixes one of its rich points, then it fixes its other rich point also.

9.5. If A leaves each of two different intersecting lines invariant, then it fixes their intersection.

9.6. If A fixes two points on a line, then it leaves the line invariant.

9.7. Let p be a rich point, and let p_1, p_2, p_3 be the rich points on the three diagonal (ranking) lines through p. If A fixes p, p_1 and p_2, then it fixes p_3.

9.8. Let p be a rich point, and let p_1, p_2, p_3 be the rich points on diagonal (ranking) lines through p. If A fixes p_1, p_2, p_3, then A fixes p.

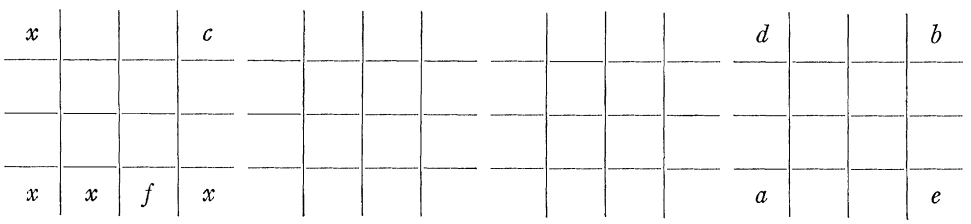

FIG. 9. Fixed points of A.(1) a and b are fixed, by 9.7; c, d and e are fixed, by 9.8; f is fixed, by 9.3.

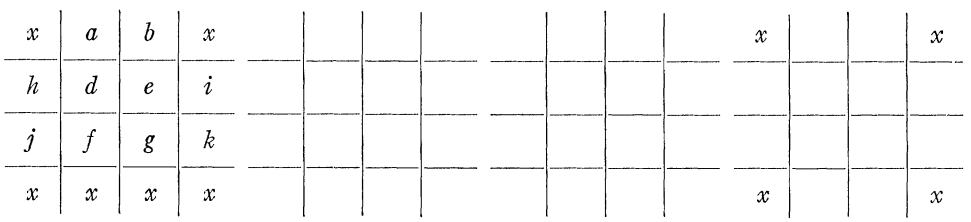

FIG. 10. Fixed points of A.(2).

Now suppose that A fixes (0, 0, 0), (1, 0, 0), (3, 0, 0) and (0, 3, 0): a is on the invariant (9.6) line through (0, 3, 0) and (3, 3, 0), hence aA is one of the poor points a or b. But a is collinear with (1, 0, 0) while b is not, and (1, 0, 0) is fixed, so $aA = a$. b is fixed (9.3).

The line through a and d is invariant (9.6), as is the line through g and d (9.6) so d is fixed (9.5). Similarly, e, f and g are fixed.

The line through d and e is invariant, as is the line through (0, 0, 0) and (0, 3, 0), so h is fixed. Similarly i, j and k are fixed.

The sequence of arguments above showed that from the six fixed points of the left square of Figure 10 we could deduce that all the points of that square are fixed. Each of the other faces of the cube can be treated similarly. Thus, all of the exterior points of the cube are fixed. But each interior point is on the intersection

of two lines each of which intersects the surface, hence 9.6 and 9.5 show the interior points fixed as well.

This completes the proof of 9.2, and thus $\overline{R}\times\overline{F}=\overline{A}_3$.

10. Transitivity. We have succeeded in discovering the group of automorphisms $\overline{A}_3=\overline{R}\times\overline{F}$ of the 3 DT board. It turns out to be isomorphic to the direct product of the group of rotations of the cube by the group of symmetries of the square.

We will now show that $\overline{A}_3$ is transitive over each of the invariant sets of 4.3. First note that if $\overline{A}_3$ is transitive over the set $\overline{S}$, and also over the set $\overline{T}$, and if some A in $\overline{A}_3$ maps a member of $\overline{S}$ into a member of $\overline{T}$, then $\overline{A}_3$ is transitive over $\overline{S}\cup\overline{T}$.

10.1. *Rich Points.* Clearly $\overline{R}$ is transitive over the set $\overline{S}$ of exterior rich points and the set $\overline{T}$ of interior rich points. But E maps a point of $\overline{S}$ into a point of $\overline{T}$. Therefore, $\overline{A}_3$ is transitive over $\overline{S}\cup\overline{T}$, the rich points.

10.2. *Poor points.* Clearly $\overline{R}$ is transitive over the set $\overline{S}$ of poor edge points, and also over the set $\overline{T}$ of poor points on a face but not on an edge. But E maps $\overline{S}$ points into $\overline{T}$ points, so $\overline{A}$ is transitive over $\overline{S}\cup\overline{T}$, the poor points.

Full lines. Clearly $\overline{R}$ is transitive over the full lines.

Empty lines. Clearly $\overline{R}$ is transitive over the empty lines.

Diagonal lines. The diagonal lines can be partitioned into two classes of 12 lines each: the set $\overline{S}$ of these that lie on a face of the cube, and the set $\overline{T}$ of these that do not. Clearly $\overline{R}$ is transitive over each of these sets, while E maps the $\overline{S}$-line $\{(0, 0, 0), (1, 1, 0), (2, 2, 0), (3, 3, 0)\}$ into the $\overline{T}$-line $\{(0, 0, 1), (1, 1, 1), (2, 2, 1), (3, 3, 1)\}$.

Ranking lines. The ranking lines can be partitioned into two classes of 12 lines each: the set $\overline{S}$ of those that are edges of the cube, and the set $\overline{T}$ of those that are not. Clearly $\overline{R}$ is transitive over $\overline{S}$ and $\overline{T}$, while E maps the $\overline{S}$-line. $\{(0, 0, 0), (1, 0, 0), (2, 0, 0), (3, 0, 0)\}$ into the $\overline{T}$-line $\{(0, 1, 1), (1, 1, 1), (2, 1, 1), 3, 1, 1)\}$.

11. Applications to the game of 3DT. Of the 192 automorphisms $\overline{A}_3$ of the 3DT board, 48 are obvious (the symmetries of the cube), while the others are not so obvious. This is an extraordinarily large group of automorphisms for a board game: contrast the order of the automorphism group for checkers (1), chess (1), checkers with kings only (4), Go and Go-moku (8), Ticktacktoe (8). In any attempt to analyze the game, or to provide a heuristic computer program for playing it, this group will provide a powerful method for pruning the move tree by eliminating positions equivalent to one already considered. For example, it should be evident from 10 that there are essentially two opening moves: playing on a rich point, and playing on a poor point.

The research reported in the paper was sponsored by the Air Force Electronic Systems Division, Air Force Systems Command, under Contract AF 19(628)2390. INFINITELY DIVISIBLE DISTRIBUTIONS ON CYCLIC GROUPS

LEOPOLD FLATTO, Yeshiva University and P. A. SCHEINOK, Hahnemann Medical College

I. Introduction. The theory of infinitely divisible distributions on the real line, their characterization and application to the limit theorems of the Theory of Probability (see [3], [4], and [5]) although not formulated until the mid-nineteen-thirties is now classic fare in the basic graduate curriculum in Probability and Statistics. At the same time, in the past fifteen years probabilists have been trying to extend many of the classic results in the Theory of Probability relating to the real line to abstract spaces having certain algebraic relations defined on them. They have thus been investigating such structures as groups, semigroups, topological vector spaces, and algebras to see what the counterpart of the classic Theory of Probability is within such individual frameworks. For a fairly recent summation of results in this area see Grenander [2]. One of the subjects which is being studied in the setting of such algebraic structures is that of the characterization of infinitely divisible distributions. In [1] W. Böge proved a general representation theorem which characterizes the infinitely divisible distributions on finite groups, and answered certain uniqueness questions relating to such a representation. Although Böge's generalized treatment can nontrivially be particularized to the situation discussed below, the authors have wished to proceed from first principles in order to see what concrete analytic representation one can give for very simple groups. In the ensuing, the cyclic groups of order three and four will be examined and characterized. (The case $n=2$ is trivial.) The complexity of the case $n=4$ leads us to believe that this method cannot be generalized to arbitrary values of n. Still, the cases $n=3, 4$ seem to be most interesting in their own right, and present us with a very elegant solution, which we believe to be pedagogically useful.

II. Basic definitions. Classically [3], the definition of infinite divisibility is as follows.

DEFINITION. *The random variable X is infinitely divisible if for every natural number n it can be represented as the sum*

$$X = Y_{n1} + Y_{n2} + \cdots + Y_{nn}$$

of n independent identically distributed random variables $Y_{n1}, Y_{n2}, \cdots, Y_{nn}$.

Let $F_X(x)$ be the distribution function of X, and let $\phi_X(t) = \int_{-\infty}^{\infty} e^{itx} dF_X(x)$ be its characteristic function (Fourier-Stieltjes transform of $F_X(x)$). Then by the well-known properties of characteristic functions, X will be infinitely divisible if and only if for every natural number n, $\phi_X(t)$ is the nth power of some characteristic function $\phi_{Y_{ni}}(t)$. This characteristic function $\phi_{Y_{ni}}$ is naturally dependent on n.

Many of the famous classic probability distributions are infinitely divisible,

which of course is what led the impetus to research in this area. We shall see several examples of this.

Example 1: Let X have the Gaussian distribution with mean μ and variance $\sigma^2(X\sim N(\mu, \sigma^2))$, then for every natural number $n>0$, $X=\sum_{i=1}^{n} Y_{ni}$ where each $Y_{ni}\sim N(\mu/n, \sigma^2/n)$, $i=1, \cdots, n$.

Example 2: Let X have the Poisson distribution with mean λ, $(X\sim P(\lambda))$, then for every natural number $n>0$, $X=\sum_{i=1}^{n} Y_{ni}$, where each $Y_{ni}\sim P(\lambda/n)$, $i=1, \cdots, n$.

It is easiest to use the properties of characteristic functions in order to verify these examples.

In our situation, consider a random variable X which assumes the values $0, 1, \cdots, n-1$. Suppose addition of random variables is done modulo n, and let $p(k)=\Pr\{X=k\}$ $0\leqq k\leqq n-1$. We wish to find criteria for p to be infinitely divisible. To do this we shall consider the transform $\hat{p}$, and our criteria will be on the real and imaginary parts of $\hat{p}$. Let $\zeta=e^{2\pi i/n}$, then one defines the Fourier transform as

$$\hat{p}(j) = \sum_{k=0}^{n-1} p(k)\zeta^{kj} \tag{2.1}$$

and one has the inversion formula

$$p(k) = \frac{1}{n}\sum_{j=0}^{n-1} \hat{p}(j)\zeta^{-jk}. \tag{2.2}$$

If there exists a probability distribution $g(k)$ such that $p=g*\cdots*g$, an n-fold convolution, then this is equivalent to $\hat{p}=\hat{g}^n$. We also note that the conditions for p to be a probability distribution

$$p(k) \geqq 0 \qquad (0 \leqq k \leqq n-1) \tag{2.3}$$

$$\sum_{k=0}^{n-1} p(k) = 1 \tag{2.4}$$

are equivalent respectively to the conditions on the transform,

$$\sum_{j=0}^{n-1} \hat{p}(j)\zeta^{-jk} \geqq 0 \qquad (0 \leqq k \leqq n-1) \tag{2.3'}$$

$$\hat{p}(0) = 1. \tag{2.4'}$$

To characterize the infinitely divisible $p(k)$ one wishes to find conditions on $\hat{p}(j)$ $(0\leqq j\leqq n-1)$ satisfying (2.3') and (2.4') which will guarantee that for each integral $m\geqq 0$, $\hat{p}^{1/m}$ will also satisfy (2.3') and (2.4'). We shall examine in detail the cases $n=3, 4$. We note that

$$\hat{p}(n-k) = \overline{\hat{p}(k)} \qquad (k = 0, 1, 2, \cdots, n-1) \tag{2.5}$$

a fact very useful in the sequel.

III. The case $n=3$. In this case one notes that the condition (2.1) implies that the points $\hat{p}(0)$, $\hat{p}(1)$, $\hat{p}(2)$ lie inside or on the triangle with vertices at 1, ω, ω^2 in the complex plane, where ω represents one of the cube roots of unity. We have $\hat{p}(0)=1$, $\hat{p}(2)=\overline{\hat{p}(1)}$, and we see that $\hat{p}$ is infinitely divisible if and only if $[\hat{p}(1)]^{1/m}$ lies inside the triangle for every positive integer $m\geqq 1$.

Write $p(1)=re^{i\theta}$, $0\leqq|\theta|\leqq\pi$. The result we seek is embodied in the following theorem.

THEOREM. *For the case $n=3$, $p(k)$ is an infinitely divisible law if and only if $\hat{p}(1)=re^{i\theta}$ is such that $r\leqq e^{-\sqrt{3}|\theta|}$, $0\leqq|\theta|\leqq\pi$.*

Proof. Suppose $p(k)$ is infinitely divisible. Because of symmetry it suffices to restrict oneself to points $\hat{p}(1)$ in the upper half of the complex plane. By hypothesis, the point $[\hat{p}(1)]^{1/m}=r^{1/m}e^{i(\theta+2\pi k)/m}$ must lie inside the triangle $(1, \omega, \omega^2)$ for some value of k, $k=0, 1, \cdots, m-1$. If one lets $m=3j$, $j=1, 2, \cdots$, then it is clear that if there is an mth root which lies inside the triangle, there will always be one in the sector $|\theta|\leqq\pi/3$ which will lie inside the triangle, and since all the mth roots are on the circle $|Z|=r^{1/m}$, it is clear that the root $r^{1/m}e^{i\theta/m}$ which is closest to the axis, must also be inside the triangle. Thus, if we consider the line $r=\frac{1}{2}\sec(\theta-\pi/3)$ which connects the points 1 and ω, we demand that $\hat{p}(1)=re^{i\theta}$ be such that

$$r^{1/m}\leqq\tfrac{1}{2}\sec\left(\frac{\theta}{m}-\frac{\pi}{3}\right)$$

for an infinity of m. In the limit as $m\to\infty$, we have

$$\left[\frac{1}{2}\sec\left(\frac{\theta}{m}-\frac{\pi}{3}\right)\right]^m\to e^{-\sqrt{3}\theta}.$$

Thus for an infinitely divisible law $r\leqq e^{-\sqrt{3}\theta}$, and by symmetry $r\leqq e^{-\sqrt{3}|\theta|}$, $0\leqq\theta\leqq\pi$. Conversely, let $r\leqq e^{-\sqrt{3}\theta}$. Then we have the following result.

Contention: Let

$$f(\theta)=\begin{cases}\frac{1}{2}\sec(\theta-\pi/3) & 0\leqq\theta\leqq 2\pi/3\\ -\frac{1}{2}\sec\theta & 2\pi/3\leqq\theta\leqq\pi.\end{cases}$$

Then $f^m(\theta/m)\epsilon\downarrow$ (is nonincreasing).

Proof: $f^m(\theta/m)\epsilon\downarrow$ if and only if $m\log f(\theta/m)\epsilon\downarrow$ which would follow from $(1/\theta u)\cdot\log f(\theta u)\epsilon\uparrow$ in $0\leqq u\leqq 1$. Now consider $1/x\log f(x)$. This expression $\epsilon\uparrow$ in $0\leqq x\leqq 1$ if and only if

$$\frac{1}{x}[\log f]'-\frac{1}{x^2}[\log f]\geqq 0.$$

This is equivalent to showing that $[\log f]'\geqq\log f/x$ which would follow from $(\log f)''=(ff''-f'^2)/f\geqq 0$. Direct computation, however, shows that for $f(\theta)$ defined above, $ff''-f'^2\geqq 0$, so that the contention is proved.

We note that the latter contention establishes the converse, since $r \leqq e^{-\sqrt{3\theta}}$ implies that $r^{1/m} \leqq f(\theta/m)$ for every m, so that there is an mth root inside the triangle $(1, \omega, \omega^2)$ for $m = 1, 2, \cdots$ and $p(k)$ is thus infinitely divisible.

IV. The case $n = 4$. In this situation we have $\hat{p}(0) = 1$, $\hat{p}(2)$ is real, and $\overline{\hat{p}(1)} = \hat{p}(3)$. The condition (2.3′) then becomes

$$\begin{array}{ll} \text{(a)}\ 1 + \hat{p}(1) + \hat{p}(2) + \overline{\hat{p}(1)} \geqq 0 & \text{(c)}\ 1 - \hat{p}(1)i + \hat{p}(2) - \hat{p}(1) \geqq 0 \\ \text{(b)}\ 1 - \hat{p}(1)i - \hat{p}(2) + \overline{\hat{p}(1)i} \geqq 0 & \text{(d)}\ 1 + \hat{p}(1)i - \hat{p}(2) - \hat{p}(1)i \geqq 0. \end{array} \tag{4.1}$$

One notes that (a) and (c) are equivalent to

$$| \operatorname{Re} \hat{p}(1) | \leqq \frac{1 + \hat{p}(2)}{2}, \tag{4.2a}$$

while (b) and (d) are equivalent to

$$| \operatorname{Im} \hat{p}(1) | \leqq \frac{1 - \hat{p}(2)}{2}. \tag{4.2b}$$

Geometrically, this means that $-1 \leqq \hat{p}(2) \leqq 1$, and for fixed $\hat{p}(2)$, $\hat{p}(1)$ is in shaded rectangle in Figure 1.

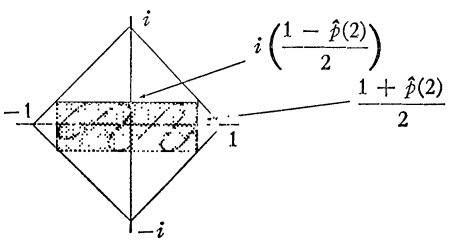

FIG. 1

To say that $p(k)$ has an mth root is equivalent to the conditions

$$| \operatorname{Re} [\hat{p}(1)]^{1/m} | \leqq \frac{1 + [\hat{p}(2)]^{1/m}}{2}, \tag{4.3a}$$

and

$$| \operatorname{Im} [\hat{p}(1)]^{1/m} | \leqq \frac{1 - [\hat{p}(2)]^{1/m}}{2}, \tag{4.3b}$$

where we take the mth root to be positive. For m even, we might have taken the mth root to be negative, in which case we would have the inequalities

$$| \operatorname{Re} [\hat{p}(1)]^{1/m} | \leqq \frac{1 - [\hat{p}(2)]^{1/m}}{2}, \tag{4.3′a}$$

and

$$(4.3'b) \qquad |\operatorname{Im} [\hat{p}(1)]^{1/m}| \leqq \frac{1 + [\hat{p}(2)]^{1/m}}{2}.$$

If $\hat{p}(2)$ is to have a real mth root for m even, then clearly $0 \leqq \hat{p}(2) \leqq 1$. Since the rectangle in Figure 1 is symmetric about x-axis we can again write $\hat{p}(1) = re^{i\theta}$, where $0 \leqq \theta \leqq \pi$. Also write $\hat{p}(2) = B$.

LEMMA 1. $\lim_{m\to\infty} ((1+B^{1/m})/2)^m = \sqrt{B}$.

Proof: For $B=0$ or 1 this is obvious. Assume then that $0<B<1$ so that $B=e^{-b}$ where $0<b<\infty$.

$$\frac{1 + B^{1/m}}{2} = \frac{1 + e^{-b/m}}{2} = 1 - \frac{b}{2m} + O\left(\frac{1}{m^2}\right)$$

$$\therefore \quad \log\left(\frac{1 + B^{1/m}}{2}\right)^m = m \log\left(\frac{1 + B^{1/m}}{2}\right)$$

$$= m \log\left(1 - \frac{b}{2m} + O\left(\frac{1}{m^2}\right)\right) = -\frac{b}{2} + O\left(\frac{1}{m}\right).$$

Thus $\lim_{m\to\infty} ((1+B^{1/m})/2)^m = e^{-b/2} = \sqrt{B}$.

LEMMA 2. $((1+B^{1/m})/2)^m \epsilon \downarrow$ for $m=1, 2, \cdots, (B>0)$.

Proof: $((1+B^{1/m})/2)^m \epsilon \downarrow$ is equivalent to $m \log ((1+B^{1/m})/2) \epsilon \downarrow$ which follows from $f(u) = 1/u \log ((1+B^u)/2) \epsilon \uparrow$ for $0 \leqq u \leqq 1$. Let $g = (1+B^u)/2$. Then $f(u) \epsilon \uparrow$ if $f' = [(1/u) \log g]' \geqq 0$. Thus one must show that $\log g + u[\log g]' \geqq 0$ which is guaranteed by $-[\log g]' + [u(\log g)']' \geqq 0$, or simply by $[\log g]'' \geqq 0$. But $[\log g]'' = (gg'' - g'^2)/g^2$, and $gg'' - g'^2 = \frac{1}{4}(\log B)^2 B^u \geqq 0$ thereby proving the lemma.

Let d be the semi-diagonal of the rectangle in Fig. 1. Then $d = [(1+B^2)/2]^{1/2}$. It also follows from the equations (4.3) that if p is to be infinitely divisible for every m, then

$$r^{1/m} \leqq \left(\frac{1 + B^{2/m}}{2}\right)^{1/2} \quad \text{or} \quad r \leqq \left(\frac{1 + B^{2/m}}{2}\right)^{m/2}.$$

Thus $r \leqq \sqrt{B}$ if we have infinite divisibility. Now by Lemma 2, $r \leqq \sqrt{B}$ implies that $r \leqq (1+B^{1/m}/2)^m$, or $r^{1/m} \leqq (1+B^{1/m}/2)$. This tells us that the mth roots of $\hat{p}(1)$ lie on a circle whose radius is less than or equal to the length of the rectangle $[1+(\hat{p}(2))^{1/m}]/2$. Thus if there is a root inside the rectangle there has to be one in that portion of the rectangle in the right half-plane, and the closest one to the x-axis will again have the argument θ/m. Hence, from (4.3) one gets for odd m that

$$(4.4a) \qquad r^{1/m} \cos\frac{\theta}{m} \leqq \frac{1 + B^{1/m}}{2}, \qquad (4.4b) \qquad r^{1/m} \sin\frac{\theta}{m} \leqq \frac{1 - B^{1/m}}{2}.$$

From (4.4a) no new information is gained. From (4.4b) multiplication of both sides by m and letting $m\to\infty$ through the odd numbered integers leads to

$$\lim_{m\to\infty} m\left(\frac{1-B^{1/m}}{2}\right) = \lim_{m\to\infty} m\left(\frac{1-e^{-b/m}}{2}\right) = \frac{b}{2} = \log\frac{1}{\sqrt{B}}\,.$$

Conversely, let $r\leqq\sqrt{B}$, $\theta\leqq\log 1/\sqrt{B}$. Then we note that (4.4a) is guaranteed, since $r^{1/m}\cos\theta/m\leqq r^{1/m}\leqq(1+B^{1/m})/2$ by Lemma 2. In addition, we can show that (4.4b) holds as

$$(1-B^{1/m})\frac{r^{-1/m}}{\sin^{\theta/m}}\,\epsilon\downarrow\,.$$

The latter implies that

$$\frac{1-B^{1/m}}{2}\,\frac{r^{-1/m}}{\sin^{\theta/m}}\geqq 1$$

or that (4.4b) holds. We shall use the following lemma.

LEMMA 3: *Let* $U(0)=V(0)=0$. *Let* $U(x)$, $V(x)\geqq 0$, $U''(x)\geqq 0$, $V''(x)\leqq 0$. *Then* $U/V\epsilon\uparrow$.

Proof: $(U/V)'=(VU'-UV')/V^2$. We wish to show that $VU'-UV'\geqq 0$. But $VU'-UV'=0$ at $x=0$. Hence $(VU'-UV')'=VU''-UV''\geqq 0$ which proves our lemma.

We now note that

$$\frac{(1-B^{1/m})r^{-1/m}}{\sin\theta/m} = \left(\frac{B^{1/2}}{r}\right)^{1/m}\frac{B^{-1/2m}-B^{1/2m}}{\sin\theta/m}\,.$$

By hypothesis $B^{1/2}/r\geqq 1$, so that $(B^{1/2}/r)^{1/m}\epsilon\downarrow$. Thus it suffices to show that $[(B^{-1/2m}-B^{1/2m})/(\sin\theta/m)]\epsilon\downarrow$ which would follow from

$$\frac{B^{-u/2}-B^{u/2}}{\sin\theta u}\,\epsilon\uparrow \quad \text{for } 0\leqq u\leqq 1.$$

If we let $U=B^{-u/2}-B^{u/2}$, $V=\sin\theta u$ we see that the hypotheses of Lemma 3 are satisfied, and the conclusions of the lemma prove our contention.

We have thus proved the following theorem for the case $n=4$.

THEOREM. *For* $n=4$, $p(k)$ *is an infinitely divisible law if and only if* $\hat{p}(1)=re^{i\theta}$, $\hat{p}(2)=B$ (*real*), *are such that* (i) $r\leqq\sqrt{B}$ *and* (ii) $\theta\leqq\log 1/\sqrt{B}$, $0\leqq B\leqq 1$.

To conclude the discussion on $n=4$, one notes that one gets the following pictorial representation of the transforms of the infinitely divisible laws. In each case the rectangle's semi-length along the x-axis is $(1+B)/2$, while the semi-length along the y-axis is $(1-B)/2$, where $B=\hat{p}(2)$.

BETWEEN T_1 AND T_2

ALBERT WILANSKY, Lehigh University

1. There has been an outbreak recently of discussion in the MONTHLY on the subject of the Hausdorff separation axiom T_2. Specifically, it has been noted that various consequences of T_2 are or are not sufficient to imply it. There is a considerable amount of duplication in these results. See [3], [5], [6], [8], [10], [12], [13], [14], [15]. The object of this article is to introduce some systemization into the discussion, to point out its importance, and to show some surprising contact (Theorem 5) with a concept, k space, which has been introduced independently and for quite other purposes.

One possible importance of separation axioms weaker than T_2 lies in the fact that if X is a topological space and X^+ its one point compactification ($X^+ = X \cup \{\infty\}$, neighborhoods of ∞ are complements of compact closed subsets of X, see [7] Chapter 5, Theorem 21) then X^+ is not T_2 unless X is itself T_2 and locally compact. But one may ask what degree of separation X^+ has if X is T_2

and has some other pleasant property. An example of a result of this type is the contact with k space mentioned above. Another instance occurs in [1], Theorems 5.1, 5.3.

2. We now introduce two separation axioms, making no claim of novelty. (In [8], the name CC is applied to what we here call a compact KC space. In [1], J_1' is used for KC.)

DEFINITION. *A topological space is called a KC space if every compact set is closed, and a US space if every convergent sequence has exactly one limit to which it converges.*

In Theorem 3.1 of [1], equivalences are given between KC and separation properties of compact sets.

THEOREM 1. $T_2 \Rightarrow KC \Rightarrow US \Rightarrow T_1$; *but no converse implication holds even if the space is compact.*

The first implication is standard. See for example [11] Section 9.5, Corollary 3 or [7], Chapter 5, Theorem 7. The third implication holds because in a non-T_1 space there is a constant sequence with more than one limit. Finally, to prove the second implication we note first that KC implies T_1 since each singleton is compact. Next let X be a T_1 space which is not US. Then there exists a sequence $\{x_n\}$ which converges to two distinct limits, a, b. Now $\{b\}$ is closed; hence its complement is a neighborhood of a and there exists n_0 such that $n \geqq n_0$ implies $x_n \neq b$. Let $K = \{a, x_{n_0}, x_{n_0+1}, \cdots\}$. Then K is compact. But K is not closed, since $b \in \overline{K}$. Thus X is not a KC space.

A compact T_1 space need not be US (Example 1, below); a compact US space need not be KC (Example 4); and a compact KC space need not be T_2 (Example 2).

Note. The axiom T_{AB} of [1] lies between KC and US.

The following is a standard example.

Example 1. Let X be a countably infinite set and give X the topology in which a proper subset is closed if and only if it is finite. This is the cofinite, or minimal T_1 topology. It makes X a compact T_1 space but not a US space, since every sequence of distinct members of X converges to every member of X.

If in Example 1, X is uncountable and "finite" is replaced by "countable" we obtain a KC, non-T_2 space. This example has been cited frequently in recent issues of the MONTHLY and occurs in several text books.

For the next result see [3], [5], [6].

THEOREM 2. *For first countable spaces, $T_2 \equiv KC \equiv US$.*

The topology of a first countable space is determined by the behavior of sequences; thus $US \Rightarrow T_2$ and the result follows from Theorem 1.

DEFINITION. *A topological space X is called locally compact if each neighborhood of each point includes a compact neighborhood of that point.*

The next result, with Theorem 1, emphasizes the fact that a compact space need not be locally compact.

THEOREM 3. *For locally compact spaces,* $T_2 \equiv KC$.

If X is a locally compact space the set of compact neighborhoods of each point is a local base; hence, if, in addition, X is KC, the set of closed neighborhoods of each point is a local base. Thus X is regular, hence T_3 (by Theorem 1).

3. KC spaces have the following advantage over T_2 spaces. (For proofs see [8] Theorem 2, Example 1 and [11], p. 162, Theorem 3 and preceding discussion.)

A compact T_2 topology is maximal compact but not conversely. A compact KC topology, however, is maximal compact, and now the converse does hold—a maximal compact topology is KC. See [1], p. 201, last 6 lines.

4. As mentioned earlier, if X is T_2 but not locally compact, X^+, the one-point compactification of X, is not T_2. But X^+ may be T_1, US, KC, etc. and it is very reasonable to ask what properties of X lead to these. It is easy to check that X^+ is T_1 if and only if X is T_1. For US the situation is more complicated (see Section 5), and for KC we have Theorem 5, below, which we regard as our main result.

THEOREM 4. *If* X *is* KC, X^+ *is* US.

Let X be KC and let $\{x_n\}$ be a sequence in X^+ with $x_n \to a \neq \infty$. Since X is a neighborhood of a in X^+ we have $x_n \neq \infty$ for sufficiently large n, say $n \geqq n_0$. Let $K = \{a, x_{n_0}, x_{n_0+1}, \cdots\}$. Then K is a compact subset of X and hence, by hypothesis, a closed subset of X. Thus it is a closed subset of X^+ and since $\infty \notin K$ we have $x_n \not\to \infty$. Since X is a US space $x_n \not\to b$ if $a \neq b \in X$.

We shall see (Example 5) that if X is US, X^+ need not be.

DEFINITION. *A topological space is called a k space if it has the property that any subset* S *such that* $S \cap K$ *is closed for all closed compact* K *is itself closed.*

This concept is discussed in [7], pp. 230, 231, 234, 240, 241 where it is pointed out, for example, that a T_2 space is a k space if it is either first countable or locally compact. (Compare Theorems 2, 3 above, and 5, below.) See also [2], and [9], p. 76.

THEOREM 5. *Let* X *be a* KC *space. Then* X^+ *is* KC *if and only if* X *is a k space.*

The assumption that X is KC cannot be dropped since KC is hereditary. (See Example 3 below.)

In the following proof every topological concept referring to X^+ will have a $+$ superscript; those without this superscript refer to X.

Let X be a k space. Let S be a compact $^+$ subset of X^+. If $S \subset X$, S is compact, hence closed, thus closed $^+$. If, on the other hand, $\infty \in S$, let $F = S \setminus \{\infty\}$. Now let K be an arbitrary closed compact subset of X. Then K is closed $^+$, and so

$S \cap K$ is compact $^+$; hence compact, since it is a subset of S. Since X is a KC space, $S \cap K$ is closed, and so $F \cap K = S \cap K$ is closed. Since X is a k space it follows that F is closed. Then S is closed $^+$ because $X^+ \setminus S = X \setminus F$ is open, hence open $^+$.

Conversely, let X^+ be KC. Let F be a subset of X which obeys the test condition, namely $F \cap K$ is closed for every closed compact set $K \subset X$. Let $S = F \cup \{\infty\}$. Let Ω be a covering of S by open $^+$ sets. Choose $G \in \Omega$ with $\infty \in G$. Now $X \setminus G$ is closed $^+$, i.e. closed and compact; thus it meets F in a closed (hence compact) set, i.e. $F \setminus G$ is compact. Let $\Omega' = \{0 \setminus \{\infty\} : 0 \in \Omega\}$; then Ω' is an open cover of $F \setminus G$. Reducing Ω' to a finite cover of $F \setminus G$, restoring ∞ to each of its members and adjoining G gives a covering of S which is a finite subcover of Ω. We have now proved that S is compact $^+$. By hypothesis, it follows that S is closed $^+$. But $F = S \cap X$; thus F is closed. It follows that X is a k space.

COROLLARY 1. *Let X be a T_2 space. Then X^+ is always US, X^+ is KC if and only if X is a k space, X^+ is T_2 if and only if X is locally compact.*

COROLLARY 2. *Let X be a first countable T_2 space. Then X^+ is a KC space.*

We may also use Theorem 5 to give an alternate proof of the following result of Aull [1], Theorem 5.3.

COROLLARY 3. *Let X be T_2 and X^+ first countable. Then X is locally compact.*

Since X is first countable it is a k space; hence by Theorems 5 and 2, X^+ is T_2.

Example 2. To obtain a compact KC space which is not T_2 we simply take X^+ where X is first countable, T_2, but not locally compact. The special case $X =$ rationals was given in [8], Example 1.

Example 3. Let X be as in Example 1. Then every subset of X is compact; hence X is a k space. X^+ is, of course, not a KC space.

Example 4. To obtain a compact US space which is not KC, let X be a non-compact T_2 space which is not a k space, (Example 7). It now follows from Theorems 4, 5 that X^+ is compact US but not KC.

5. In this section we consider X^+ when X is US.

THEOREM 6. *Let X be a US space. Then X^+ is US if and only if, in X, every convergent sequence has a relatively compact subsequence.*

If X^+ is US, and $x_n \to a$ in X, then $x_n \nrightarrow \infty$ in X^+. Thus there is an open $^+$ neighborhood $^+$ G of ∞ such that $x_{k(n)} \notin G$ for some sequence $\{k(n)\}$. Since the complement of G is a compact closed subset of X, the closure of $\{x_{k(n)}\}$ is compact.

Conversely, let the condition hold and let $\{x_n\}$ be a sequence in X^+ with $x_n \to a \neq \infty$. Let K be the closure (in X) of a relatively compact subsequence. Then $X^+ \setminus K$ is a neighborhood $^+$ of ∞ and it is false that x_n belongs to it eventually. Thus $x_n \nrightarrow \infty$.

Example 5. Theorem 6 leaves open the question of whether there actually exists a US space X such that X^+ is not US. We now construct one. Let N be the positive integers and I the set of all infinite subsets of N. For any $S\in I$, the cardinality of $\overline{S}$, the closure of S in βN, (the Cech compactification of N) is 2^c ([4], Theorem 9.2). For each such S, let A_S be a countably infinite subset of $\overline{S}\backslash N$. Let $B=N\cup(\cup A_S\colon S\in I)$ and $X=B\cup\{t\}$, $t\in N^+\backslash N$, i.e. t is adjoined to B and assigned as neighborhoods every set which includes t and all of N except for a finite subset of N. Then X is a US space since B is T_2 and the only sequences in B which converge to t are sequences of members of N; they converge to no other member of B. (See [11], Section 14.3, Problem 20.) However, the condition of Theorem 6 fails in that $n\to t$ but $\{n\}$ has no relatively compact subsequence. To see this, let S be any infinite subset of N and S_X its closure in X. Now $S_X\backslash N^+$ is a subset of $B\backslash N$ which includes A_S, hence its cardinality k satisfies $\aleph_0\leqq k\leqq c$. By [4], Theorem 9.3 and top p. 134, $S_X\backslash N^+$ is not compact. But it is a closed subset of S_X, since N^+ is open in X; thus S_X is not compact.

Example 6. Theorem 6 also leaves open the question of whether X must be KC if X^+ is US, i.e. whether or not the condition of Theorem 6 is sufficient for X to be KC. (By Theorem 4, it is necessary.) We give an example (with X not compact to avoid triviality) in which X is not KC but X^+ is US. Let N, βN be as in Example 5. Let $b\in\beta N\backslash N$, $t\in N^+\backslash N$, $X=(\beta N\backslash\{b\})\cup\{t\}$. Now X is not KC since $N\cup\{t\}$ is dense and compact (a convergent sequence and its limit). However, we shall show that X satisfies the criterion of Theorem 6. Let $\{x_n\}$ be a convergent sequence. If $x_n\to a\neq t$, then $\{a, x_1, x_2, \cdots\}$ is compact and closed, (or it could be observed that $\{x_n\}$ has finite range). If $x_n\to t$, we must have $x_n\in N$ eventually. Now any infinite subset of N must have an infinite subset S with $b\notin\overline{S}$, the closure of S in βN, (otherwise N would not be C^* embedded in βN, see [11], Section 14.3, Application 2 and Problem 20). Then S is relatively compact in $\overline{S}$.

Example 7. A noncompact T_2 space which is not a k space. Let $X=N\cup\{b\}$, where $b\in\beta N\backslash N$. If S is any infinite subset of N, neither S nor $S\cup\{b\}$ is closed in βN, hence neither is compact. Thus X is pseudo-finite, i.e. all its compact sets are finite. If X were a k space, it would, being pseudo-finite, be discrete.

6. The following open question appears to be interesting. Must a locally compact US space be T_2? (The definition of local compactness is given in Section 2.)

7. The condition on 0-sequences given by Robertson and Franklin (this MONTHLY, 72 (1965) 510) is strictly between US and T_1.

8. An exhaustive study of the relationships among T_2, US, first and second countability, and countability, is given by W. Sierpinski, Soc. Sci. Lett. de Varsovie, C.R. Classe III (40 (1957) 66–78. (See Math. Reviews 12 (1951) p. 195.) The results overlap slightly with parts of Theorems 1 and 2.

DENSENESS AND COMPLETENESS IN CERTAIN FUNCTION SPACES

HENRY SHARP, JR., Emory University

1. Introduction. Let E^n denote euclidean n-dimensional space and let S^n denote the unit n-dimensional sphere embedded as a subspace in E^{n+1} centered at the origin. Consider the function space

$$T = \{f: f \text{ any function on } S^n \text{ into } S^n\}$$

metrized by the familiar formula

$$\rho(f, g) = \sup d(f(x), g(x)),$$

where $f, g \in T$ and d is the metric in S^n. Note that the members of T need not be continuous; we use the word "mapping" when continuity is implied.

We shall investigate a number of subspaces of T. The two main results (Theorems 3 and 6) are known, but the general development leads to several interesting by-products. An application of Theorem 3, together with an outline of the proof, appears in [4, p. 561]; a broader version of Theorem 6 is discussed in [3, Chapter 7].

Repeated use will be made of the facts that a closed subset of a complete space is complete and that a G_δ-subset of a complete space can be assigned a topologically equivalent metric under which it is complete. The space T, above, is complete under the metric ρ [5, pp. 27–29]. Throughout the following, we fix "p" as the north pole of S^n, i.e. $p=(0, \cdots, 0, 1)$, and if X is a subset of T then X_p will denote those functions in X which leave p fixed.

2. Mappings on S^n. In this section we consider the subspaces

$$M = \{f \in T: f \text{ continuous on } S^n\}$$
$$G = \{f \in M: f \text{ is onto}\}$$
$$H = \{f \in M: f \text{ is one-to-one}\},$$

as well as M_p, G_p, and H_p.

The space M is a closed, hence complete, subspace of T [3, p. 227]. The topology on M induced by the metric ρ is identical with the compact-open topology [3, p. 230]. It is an immediate consequence that the subspaces M_p and G are closed, hence complete, for in each case the complement is a member of the sub-base of the *c-o* topology.

The first theorem below is an immediate consequence of the fact that S^n is not homeomorphic with a proper subset of itself. Here, however, we derive this result from Theorem 1, which is proved from the Borsuk-Ulam theorem: *if f maps S^n into E^n, then f maps a pair of antipodal points into the same point.* [1, p. 50].

THEOREM 1. $H \subset G$.

Proof. If $f \in M-G$, then there is a point $q \in S^n - f(S^n)$. Let π denote a homeomorphism on $S^n - \{q\}$ onto E^n. Then πf: $S^n \to E^n$ is continuous and by the Borsuk-Ulam theorem there is a point $x \in S^n$ such that $\pi f(x) = \pi f(-x)$, where x and $-x$ are antipodal points. It follows that f is not one-to-one.

Since the space H consists of the homeomorphisms on S^n (one-to-one maps on a compact space to a Hausdorff space), Theorem 1 implies

COROLLARY 1. *If h: $S^n \to S^n$ is a homeomorphism, then h is onto.*

Corresponding to any $f \in M$ and any $\epsilon > 0$, it is easy to find a function $g \in T-M$ such that $\rho(f, g) < \epsilon$; thus $T-M$ is dense in T. Furthermore, the example of a rotation through an arbitrarily small angle shows that the set $M-M_p$ is dense in M. On the other hand, it is a consequence of the Borsuk-Ulam theorem that the set $M-G$ is not dense in M. For if f is any map in $M-G$ there is an x such that $f(x)=f(-x)$; thus $\rho(f, \text{identity}) > 1$, so the identity map is an interior point of G.

With attention restricted now to subspaces of M_p, it follows as above that G_p is closed in M_p and that G_p has nonempty interior. By Theorem 1, we may consider H_p a subspace of G_p, and again it is easy to construct examples which show, in this case, that G_p-H_p is dense in G_p but that H_p is not closed in G_p.

Nevertheless, using an argument involving ϵ-mappings [2, p. 57], it follows that H_p is a G_δ-subset of G_p hence is topologically complete.

THEOREM 2. *Let $f: E^n \to E^n$ be a homeomorphism. Then f is onto iff the image of each unbounded sequence is unbounded.*

Proof. Suppose first that $f(E^n) = E^n$, that $\{x_i\}$ is an unbounded sequence, and that the image sequence $\{y_i\}$ is bounded. We may assume that $\{x_i\}$ has no cluster point. There exists a subsequence $\{y_i'\}$ of $\{y_i\}$ converging to a point y and a point x such that $y = f(x)$. But f^{-1} is continuous at y, hence $\{x_i\}$ must have a cluster point, contrary to the assumption. Next, suppose that the image of each unbounded sequence is unbounded. By Brouwer's theorem on invariance of domain [2, p. 95], $f(E^n)$ is open in E^n. If y is any limit point (in E^n) of $f(E^n)$, then there is a bounded sequence $\{y_i\}$ of distinct points in $f(E^n)$ converging to y. If $x_i = f^{-1}(y_i)$, then $\{x_i\}$ is bounded and hence contains a convergent subsequence with limit x. But f is continuous at x, hence $y \in f(E^n)$. Since $f(E^n)$ is both open and closed in E^n, $f(E^n) = E^n$.

THEOREM 3. *The set Φ of all homeomorphisms on E^n onto itself can be topologized as a complete metric space homeomorphic to H_p.*

Proof. By Theorem 2 there is a natural one-to-one correspondence, via the stereographic projection $\pi: S^n - \{p\} \to E^n$ with center p, between Φ and H_p. For suppose $f: S^n \to S^n$ is a function which is onto, one-to-one, and leaves p fixed. Then if f is continuous at all $x \neq p$, f is continuous also at p and hence $f \in H_p$. The correspondence is then $f = \pi^{-1}\phi\pi$, where $\phi \in \Phi$ and $f \in H_p$.

3. Functions on S^n. In this section we consider the subspaces

$$T_p = \{f \in T : f(p) = p\},$$
$$F_p = \{f \in T_p : f \text{ continuous at each } x \neq p\},$$
$$Q_p = \{f \in F_p : f(S^n) \text{ is dense in } S^n\}.$$

In addition, we establish certain relations between these spaces and those considered in Section 2.

If $f \in T - T_p$ and if $d(p, f(p)) = \epsilon$, then $\rho(f, g) < \epsilon$ implies $g \in T - T_p$; hence T_p is closed in T. Again, the example of a rotation through a sufficiently small angle shows that $T - T_p$ is dense in T. It follows by equally simple arguments that $T_p - F_p$ is both open and dense in T_p.

The space M_p (of Section 2) is a subset of F_p. By extending slightly the useful notion of *compact mapping* [6, p. 90], this subspace has a simple characterization. Define $f \in T$ to be *compact* iff for each set K closed in S^n the set $f^{-1}(K)$ is closed in S^n.

THEOREM 4. *Suppose $f \in F_p$. Then $f \in M_p$ iff f is compact.*

Proof. If $f \in M_p$ then f is continuous on S^n, hence is compact. On the other hand, if $f \in F_p - M_p$ there is a sequence $\{x_i\}$ such that $x_i \to p$, $f(x_i) \neq p$, and p

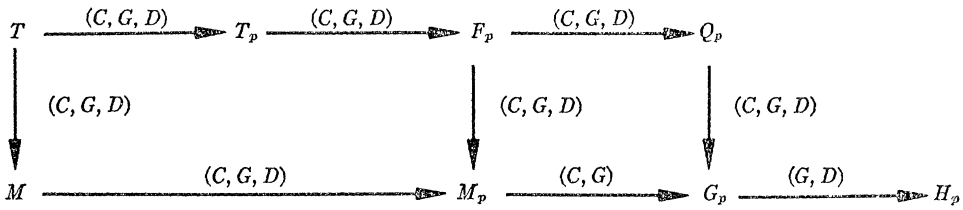
is not a cluster point of $\{f(x_i)\}$. If K is the closure of the set $\{f(x_i)\}$ then K is closed but $f^{-1}(K)$ is not since it fails to contain p.

Since M_p is a closed subset of T, it follows that M_p is closed in F_p. The example of a small rotation except for a discontinuity at p (which is fixed) shows that $F_p - M_p$ is dense in F_p.

THEOREM 5. *The space $F_p - Q_p$ is both open and dense in F_p.*

Proof. If $f \in F_p - Q_p$ then there is a spherical neighborhood of radius $\epsilon > 0$ contained in $S^n - f(S^n)$. For each $g \in F_p$, if $\rho(g, f) < \epsilon/3$ then $S^n - g(S^n)$ contains a spherical neighborhood, hence $g \in F_p - Q_p$. Now let $s(\epsilon)$ denote a spherical neighborhood about p of radius ϵ and let g be defined by

$$g(x)\begin{cases} = p \text{ if } x = p, \\ = x \text{ if } x \in S^n - s(\epsilon), \\ \text{uniformly shrinks } s(\epsilon) - \{p\} \text{ onto the annular region } s(\epsilon) - \overline{s(\epsilon/2)}. \end{cases}$$



Then if $f \in Q_p$, $\rho(f, gf) < \epsilon$ but $gf \in F_p - Q_p$.

COROLLARY. *The space $F_p - (M_p \cup Q_p)$ is open and dense in F_p.*

The diagram below summarizes much of the information in Sections 2 and 3. Except for H_p, each space is complete in the metric ρ, and H_p is complete in a topologically equivalent metric. In the symbol

$$A \xrightarrow{(C, G, D)} B$$

C means that B is a closed subset of A, G means that B is a G_δ-subset of A, and D means that $A - B$ is dense in A. Absence of a letter means failure of the corresponding property.

4. Mappings on E^n. As indicated in Section 2, there is a one-to-one correspondence between H_p and the set of all homeomorphisms on E^n onto itself. One might be tempted to think that a similar one-to-one correspondence exists between F_p and the set of all mappings on E^n into itself, but the argument below shows that an additional restriction must be imposed. Again let $\pi: S^n - \{p\} \to E^n$ denote the stereographic projection with center p. Let $g: E^n \to E^n$ be a map and define $f: S^n \to S^n$ by

$$f(x) = \begin{cases} \pi^{-1} g \pi(x) & \text{if } x \in S^n - \{p\}, \\ p & \text{if } x = p. \end{cases}$$

Then $f\in F_p$ and note that $f(x)\neq p$ if $x\neq p$. Now let $f\in F_p$ and define a mapping g by

$$g(y) = \pi f\pi^{-1}(y).$$

If for some $x\in S^n-\{p\}$, $f(x)=p$, then the domain of g is not E^n but is some proper subset. If, however, $f(x)\neq p$ for $x\neq p$, then the domain of g is E^n. Define

$$K_p = \{f\in F_p: f^{-1}(p) = p\}.$$

This argument shows that there is a one-to-one correspondence between K_p and the set of all mappings on E^n into itself.

THEOREM 6. *The space K_p is complete under a metric topologically equivalent to ρ.*

Proof. We need to show that K_p is a G_δ-subset of the complete space F_p. For each positive integer j, let $s(j)$ denote the spherical neighborhood about p of radius $1/j$, and let $K_p(j)=\{f\in F_p: f^{-1}(p)\subset s(j)\}$. Let f be a limit point of $F_p-K_p(j)$; of course, $f\in F_p$ and we wish to show that $f\notin K_p(j)$. There is a sequence $\{f_i\}$ such that $f_i\in F_p-K_p(j)$ and $\rho(f_i, f)\to 0$. For each i, there is a point $x_i\in S^n-s(j)$ such that $f_i(x_i)=p$. The sequence $\{x_i\}$ has a cluster point $x\in S^n-s(j)$ and a subsequence $\{x_i'\}$ converging to x. Corresponding to $\epsilon>0$ there exist integers N_1 and N_2 such that if $i>N_1$ then $\rho(f, f_i)<\epsilon/2$, and if $i>N_2$ then $d(f(x), f(x_i'))<\epsilon/2$. Now there is an integer $m>N_1$ such that $x_m=x_i'$ for some $i>N_2$, hence

$$d(f(x), p) \leqq d(f(x), f(x_m)) + d(f(x_m), f_m(x_m)) < \epsilon.$$

Since ϵ is arbitrary, $f(x)=p$ and $f\in F_p-K_p(j)$. Thus $K_p(j)$ is open for each j, and $K_p=\bigcap_j K_p(j)$.

Again, simple examples suffice to show that F_p-K_p is not open but is dense in F_p. Furthermore, as in the proof of Theorem 5, K_p-Q_p is both open and dense in K_p. From this it follows that $K_p\cap Q_p$ is closed, hence complete, in K_p. Whether or not a similar result holds for the subspace of *onto* mappings is unknown to the author, except in the special case $n=1$.

THEOREM 7. *The space of mappings on E^1 onto E^1 is topologically complete.*

Proof. By the remark preceding Theorem 6, it will be sufficient to show that (when $n=1$) $K_p\cap Q_p$ consists in fact of the onto mappings. If $f\in K_p\cap Q_p$ then $f(S^1-\{p\})$ is both connected and dense in S^1. Hence $f(S^1-\{p\})\supset S^1-\{q\}$ for some point $q\in S^1$. If $q\neq p$ there is a point $x\neq p$ such that $f(x)=p$, which contradicts $f\in K_p$. Therefore, $q=p$ and it follows that

$$f(S^1 - \{p\}) = S^1 - \{p\}.$$

The author is indebted to the referee for several helpful comments.

This work was completed during the author's tenure as a National Science Foundation Science Faculty Fellow (1964–65).

THE MEANS OF ORDER t, AND THE LAWS OF THERMODYNAMICS

E. D. CASHWELL AND C. J. EVERETT,
Los Alamos Scientific Laboratory, University of California

Introduction. If an isolated system of n materials, with masses m_j, specific heats $c_j(T)$, and initial temperatures T_j not all equal, are placed in thermal contact, then, according to the laws of thermodynamics, the final equilibrium temperatures F_j approached must satisfy the energy-conservation equation (1st law):

$$E_2 - E_1 = \Delta E = \sum \int_{T_j}^{F_j} c_j(T) m_j dT = 0 \tag{1}$$

and moreover, must maximize the entropy change (2nd law):

$$S_2 - S_1 = \Delta S = \sum \int_{T_j}^{F_j} c_j(T) m_j dT/T. \tag{2}$$

Mathematically, these conditions imply that all $F_j = M$, the uniform, mean temperature defined by (1):

$$\sum \int_{T_j}^{M} c_j(T) m_j dT = 0,$$

and that the corresponding maximum entropy change in (2) is positive:

$$\sum \int_{T_j}^{M} c_j(T) m_j dT/T > 0.$$

The treatment of this very simple instance of the thermodynamic laws by Mahan [2] suggests an *implicit* definition of a mean $M(T_j, w_j)$ of n positive numbers T_j, relative to a set of *functions* $w_j = w_j(T)$. Curiously enough, this approach allows a completely trivial proof of a fundamental inequality (I) for such means, which not only establishes the above implications, but also yields the monotonicity property of the whole hierarchy of classical means $M(t)$ of

order t [1]. Generalization to the case of a continuous distribution $T(x)$ is straightforward, and is indicated without proof.

1. The means $M(T_j, w_j)$. Let $w_j = w_j(T)$, $j = 1, \ldots, n$, be positive, continuous functions for $T > 0$, and let T_j be arbitrary positive numbers with min $T_j \equiv T_a$, max $T_j \equiv T_b$. The function

$$e(T) \equiv e(T; T_j, w_j) \equiv \sum \int_{T_j}^{T} w_j(T')dT'$$

is obviously continuous and increasing for $T > 0$. If $T_a = T_b$, then $e(T_a) = 0$, whereas, if $T_a < T_b$, $e(T_a) < 0 < e(T_b)$. Hence *there exists a unique mean* $M \equiv M(T_j, w_j)$ *of the* T_j *relative to the* w_j, *such that* $e(M) = 0$, $M > 0$. Moreover, $M = T_a$ when all T_j are equal; otherwise, $T_a < M < T_b$.

Now, if $f = f(T)$ is positive, continuous, and *decreasing* for $T > 0$, then the mean $M_1 \equiv M(T_j, w_j f)$ of the T_j relative to the functions $w_j(T)f(T)$ is also uniquely defined, by $e(M_1; T_j, w_j f) = 0$, and we have at once the

THEOREM.

(IA) $$e(M; T_j, w_j f) \geqq 0, \quad \textit{where } M \equiv M(T_j, w_j)$$

or, equivalently,

(IB) $$M_1 \equiv M(T_j, w_j f) \leqq M(T_j, w_j) \equiv M.$$

Equality holds, in either case, if and only if all T_j *are equal.*

Proof. If $T_a = T_b$, then $M = T_a = M_1$, and equality in both instances is manifest. Otherwise ($T_a < T_b$), let l, u range over the subscripts j for which $T_j \leqq M$, $M < T_j$, respectively, and note that

$$\sum_l \int_{T_j}^{M} w_j f dT > f(M) \sum_l \int_{T_j}^{M} w_j dT = f(M) \sum_u \int_{M}^{T_j} w_j dT > \sum_u \int_{M}^{T_j} w_j f dT,$$

which yields strict inequality in (IA). Since the function $e(T; T_j, w_j f)$ is continuous and increasing for $T > 0$, with unique "zero" M_1, the equivalence of (IA) and (IB) is clear.

COROLLARY 1. *If* $m_j > 0$ *have sum* $\sum_1^n m_j = 1$, *and* $w_j \equiv m_j T^{t-1}$, *where* t *is real, then the corresponding mean* $M(T_j, w_j)$ *is the classical "mean of order* t*":*

$$M(t) = \prod T_j^{m_j} \ (t = 0); \qquad M(t) = \left(\sum m_j T_j^t \right)^{1/t} \quad (t \neq 0).$$

If $s < t$, *and* $f(T) = T^{-d}$, *where* $d = t - s > 0$, *then* $M(T, w_j f) = M(s)$, *and* (IB) *reads* $M(s) \leqq M(t)$, *strict inequality holding unless all* T_j *are equal.*

This is the monotonicity property of the means of order t for the T_j weighted by the m_j. The identification referred to above rests on explicit integration. Indeed, for $w_j(T) = m_j W'(T)$, one has $W(M) = \sum W(T_j) m_j$.

2. The maximum property. If $w_j(T), f(T)$ are given as before, together with $T_j>0$, not all equal, their mean $M\equiv M(T_j, w_j)$ provides the unique solution to the maximum problem stated in

COROLLARY 2. *For every set of $F_j>0$, satisfying the condition*

$$\text{(E)} \qquad \sum \int_{T_j}^{F_j} w_j dT = 0$$

we have

$$\text{(S)} \qquad \sum \int_{T_j}^{F_j} w_j f dT \leqq \sum \int_{T_j}^{M} w_j f dT$$

(the latter being positive), with equality if and only if all $F_j=M$.

Proof. The condition (E) is equivalent to

$$\sum \int_{T_j}^{M} w_j dT = \sum \int_{F_j}^{M} w_j dT.$$

Thus, relative to the w_j, the T_j and the F_j have the *same* mean M. But

$$\sum \int_{T_j}^{F_j} w_j f dT = \sum \int_{T_j}^{M} w_j f dT - \sum \int_{F_j}^{M} w_j f dT$$

and the result follows immediately from (IA) of the Theorem.

Note: The implications of the laws of thermodynamics cited in the introduction derive from the corollary if we set $w_j=m_j c_j(T)$, and $f(T)=1/T$.

3. The continuous case. Generalizations in many different directions are indicated. We mention one of the simplest and most interesting. Let $w(T, x)$ be a positive, continuous function of T, x, for $T>0$ and $0\leqq x\leqq 1$ (the range of x being immaterial), and $T(x)$ a positive, continuous function, with $T_a\equiv\min T(x)$, $T_b\equiv\max T(x)$ on the latter interval. If $T_a<T_b$, suppose further that, for every T properly between the two, $T(x)=T$ for only a finite set of x. Then

$$e(T) \equiv e(T; T(x), w) \equiv \int_0^1 \int_{T(x)}^{T} w(T', x) dT' dx$$

is continuous increasing for $T>0$, with a unique positive "zero" $M\equiv M(T(x), w)$, just as before. If $f(T)$ is positive, continuous, and decreasing on $T>0$, then the analogue of the Theorem holds for the means $M(T(x), wf)\leqq M(T(x), w)$. (The proof follows the same lines, with the range of x-integration split into a finite number of open intervals on which $T(x)<M$, $T(x)>M$, resp.)

The generalization of Corollary 1 then concerns a positive weighting function $m(x)$ continuous on $[0, 1]$, with $\int_0^1 m(x)dx=1$, and the function $w(T, x)\equiv T^{t-1}m(x)$. With these identifications, one obtains the monotonicity of the *integral* means of order t [1], namely

$$M(t) = \exp \int_0^1 (\log T(x))m(x)dx \quad (t = 0)$$

$$M(t) = \left(\int_0^1 T^t(x)m(x)dx \right)^{1/t} \quad (t \neq 0).$$

The analogue of Corollary 2 also follows immediately, for $F(x)$ positive and continuous. Its physical application involves a rod of density $m(x)$ per unit length, specific heat $c(T, x)$, and initial nonuniform temperature distribution $T(x)$, with the same thermodynamic implications as before; the final entropy-maximizing temperature distribution is uniform, with value $F(x) \equiv M(T(x), w)$, where $w = c(T, x)m(x)$.

Work performed under the auspices of the U. S. Atomic Energy Commission.

MATHEMATICAL NOTES

LINEAR TRANSFORMATIONS WITH INVARIANT CONES

GARRETT BIRKHOFF, Harvard University

In three dimensions, geometrical intuition readily suggests that if a linear transformation T maps into itself a closed convex cone C with vertex at the origin, then T must leave fixed some direction (ray) in C. The Brouwer fixed point theorem, applied to the convex disc of all such directions (which is homeomorphic to a sphere of one lower dimension) asserts that this is also true in n dimensions. Choosing for C the hyperoctant of all real vectors $\mathbf{x} = (x_1, \cdots, x_n)$ with all $x_i \geqq 0$ (i.e., of all "nonnegative" vectors), there follows after a little further consideration the following classic result of Perron: *If $A = \|a_{jk}\|$ is an $n \times n$ matrix with all $a_{jk} > 0$, then A has a positive eigenvector with positive eigenvalue.* Perron proved more: that this eigenvalue is simple, and greater in magnitude than any other eigenvalue of A.

In this note, a somewhat more general result will be established by a more constructive method, which uses the Jordan canonical form for complex matrices instead of Brouwer's fixed point theorem. This result is the following

THEOREM. *Let T be any linear transformation of real n-space $\boldsymbol{R}^n = V$ such that $CT \subset C$ for some proper closed convex C with nonvoid interior. Then C contains an eigenvector ω whose eigenvalue is the spectral radius of T.*

Proof. We have assumed that C satisfies

$$C \cap -C = \mathbf{0}, \quad \overline{C} = C, \quad C - C = V, \quad C + C \subset C. \tag{1}$$

From (1) there follows obviously

$$\mathbf{x}_k \in C,\ w_k \geqq \mathbf{0}, \text{ and } \sum_{k=1}^{s} w_k \mathbf{z}_k = \mathbf{0} \text{ imply that every } w_k \mathbf{z}_k = \mathbf{0}: \tag{1'}$$

since C is proper, a sum of nonzero vectors of C cannot be the zero vector $\mathbf{0}$.

We can uniquely extend V and T to a complex n-space and choose a Jordan canonical basis in this complex space, such that for each basis vector ε_j:

$$\varepsilon_{j+k} T = \lambda_j \varepsilon_{j+k} + \varepsilon_{j+k+1}, \quad k = 0, \cdots, m+1, \tag{2}$$

$$\varepsilon_{j+m} T = \lambda_j \varepsilon_{j+m}, \quad m = m(j). \tag{2'}$$

By induction on r, one can then verify that

$$\varepsilon_j T^r = \sum_{k=0}^{m} \lambda_j^{r-k} \binom{r}{k} \varepsilon_{j+k}, \quad m = m(j), \tag{3}$$

where the binomial coefficient $\binom{r}{k}$ is a polynomial of degree k in r.

Now let $\rho = \max |\lambda_j|$ be the *spectral radius* of T. The case $\rho = 0$ (i.e., all $\lambda_j = 0$) of nilpotent T is trivial. For, in this case, $CT^r = \mathbf{0}$ for some minimal r, and for this r some nonzero vector $\omega = \mathbf{x}T^{r-1} \in C$ satisfies $\omega T = \mathbf{0} = \rho\omega$.

Otherwise $\rho > 0$, and if M is the largest $m(j)$ with $|\lambda_j| = \rho$, then

$$\left(\sum c_j \varepsilon_j \right) T^r = \rho^r r^m \left(\sum_J c j e^{ir\theta_j} \varepsilon_{j+m} + 0(1) \right), \tag{4}$$

where J is the set of integers j such that

$$m(j) = M, \qquad \lambda_j = \rho e^{i\theta_j}, \qquad \varepsilon_{j+M} T = \lambda_j \varepsilon_{j+M}. \tag{4'}$$

On the other hand, the nonvoid open *interior* of C must contain vectors $\mathbf{z} = \sum c_j \varepsilon_j$ with all $c_j \neq 0$. For any such $\mathbf{z}$, consider the sequence $\mathbf{z}T^r$ of its iterated transforms. Clearly, no $\mathbf{z}T^r = \mathbf{0}$, as otherwise (4) would fail; hence every $\mathbf{z}T^r$ (which is in C since $CT \subset C$) has a *direction* in the set of directions in C. This set is *compact* since C is closed; hence the set of limits of subsequences of this sequence of directions (which may be called "ω-limit directions") is a *nonvoid* (closed) subset of C. By (4'), it contains only vectors ω of the form

$$\omega = \sum d_k \varepsilon_k, \qquad \varepsilon_k T = \rho e^{ir\theta_k} \varepsilon_k, \qquad \theta_k \text{ real}. \tag{5}$$

Such vectors ω, if nonzero, will be called *ω-vectors*. We now state without proof an elementary result.

LEMMA. *Unless the complex number $\alpha = \rho e^{i\theta}$ is positive, there exists a finite sequence of positive constants w_r such that $\sum w_r \alpha^r = 0$.*

For any $\theta_l \not\equiv 0 \pmod{2\pi}$—i.e., any nonpositive λ_l,—we can therefore construct a vector $\omega' = \sum w_r \omega T^r$ in C, which will be nonzero by (1'), such that in

$$\omega' = \sum \xi d_k' \varepsilon_k, \qquad d_k' = \sum w_r \lambda_k{}^r d_k, \tag{5'}$$

$d_k = 0$ implies $d_k' = 0$, *and* $d_l' = 0$. Hence, for *any* nonzero ω-limit vector of the form (5) in C which has a *minimum* number of nonzero coefficients d_k in (5), $d_k \neq 0$ must imply $\lambda_k = \rho$, and so the vector is an eigenvector in C with eigenvalue ρ. This completes the proof.

A NOTE ON MATRIX COMMUTATORS

R. C. THOMPSON, University of California at Santa Barbara

The purpose of this note is to offer a strengthened form and simplified proof of a theorem due to I. Sinha [1] and, as a consequence, to supply a very short proof of another theorem due to Sinha published in this MONTHLY [2]. We let I_n be the n-square identity matrix and the characteristic polynomial of matrix A is $\det(\lambda I_n - A)$.

THEOREM. *Let A, B, C be n-square nonsingular matrices with elements in an algebraically closed field such that*

$$C = ABA^{-1}B^{-1}, \qquad CA = AC, \qquad CB = BC. \tag{1}$$

Then

(i) *each eigenvalue of C is a root of unity*;

(ii) *if r is the least common multiple of the orders of the roots of unity which appear as eigenvalues of C, then $C^t - I_n$ is nilpotent if and only if r divides t*;

(iii) *if $\gamma_1, \cdots, \gamma_s$ are the distinct eigenvalues of C where γ_i has order r_i and multiplicity e_i, $1 \leqq i \leqq s$, then r_i divides e_i and the characteristic polynomials of A and B each have the form*

$$\prod_{i=1}^{s} \prod_{j=1}^{e_i/r_i} (\lambda^{r_i} - a_{ij});$$

(iv) *if γ is an eigenvalue of C then C has at least two elementary divisors of the form $(\lambda - \gamma)^h$, $h > 0$, belonging to the eigenvalue γ, with one exceptional case: $\gamma = 1$ may be a simple eigenvalue of C belonging to the single elementary divisor $\lambda - 1$*;

(v) *C is never nonderogatory when $n > 1$*;

(vi) *if $\gamma = 1$ is not an eigenvalue of C then both A and B have trace zero, hence are additive commutators.*

Proof. Replacing C, A, B with SCS^{-1}, SAS^{-1}, SBS^{-1}, respectively, throughout (1), we obtain a new equation easily derived from (1). Hence we may throw C into Jordan canonical form and assume $C = C_1 + \cdots + C_s$ (direct sum), where C_i is e_i-square and has γ_i for its only eigenvalue, $1 \leqq i \leqq s$. Then it is well known and easy to prove that $CA = AC$, $CB = BC$ imply that $A = A_1 + \cdots + A_s$,

COROLLARY 1. *If B does not have among its eigenvalues all roots of any polynomial $\lambda^u - a$ with $u > 0$, then* (1) *implies that $C - I_n$ is nilpotent.*

Proof. The hypothesis implies that each $r_i = 1$, hence $r = 1$, and (ii) supplies the result. This is Sinha's theorem in [1].

COROLLARY 2. *Over the complex field, if the eigenvalues of B lie in a cone in the complex plane with apex at the origin and apex angle $< \pi$, then* (1) *implies that $C - I_n$ is nilpotent.*

Proof. If $r_i > 1$, then the roots of (4) cannot be contained in any such cone.

COROLLARY 3. *If $n = 2$ and* (1) *holds then $C = I_2$ or $C = -I_2$.*

Proof. Since C has roots of unity of order $\leqq 2$ as eigenvalues, the eigenvalues of C are 1 or -1. If $\gamma = -1$ appears as an eigenvalue of C then $C = -I_2$, since $\gamma = -1$ belongs to at least two elementary divisors. If $\gamma = -1$ does not appear then $\gamma = 1$ is the only eigenvalue and is not simple, hence belongs to at least two elementary divisors, forcing $C = I_2$. This is Sinha's theorem in [2].

We note that explicit formulas for all solutions of (1) are given in [4], when $C = fI_n$ and f is a primitive root of unity of order n.

Added in proof: Additional results on the problem considered here have recently appeared in [5]. Still further results will appear in [6], where the problem is solved of obtaining necessary and sufficient conditions that C must satisfy in order to be representable in the form (1).

RADIAL FUNCTIONS OF CONVEX AND STAR-SHAPED BODIES

F. A. TORANZOS, University of Washington and University of Buenos Aires

The fact that the radial function of a convex body is Lipschitzian belongs to the folklore of convexity. In Theorem 1 we compute the best Lipschitz constant valid for all the convex bodies whose boundaries are contained in an annular region. In Theorem 2 we extend this result to a similar class of star-shaped bodies, answering a problem stated by Valentine ([1], p. 168, Problem 3.2). The

Lemma that precedes Theorem 2, despite its triviality, seems to be a natural and unexploited way to attack some problems involving star-shaped bodies. Clearly it is valid in any real linear space, regardless of its dimension or topology.

NOTATION. All the sets considered are in E^d, the d-dimensional euclidean space. The symbol θ denotes the origin, B the unit ball and U the unit sphere centered at θ. The closed segment joining a and b is denoted by $[a, b]$ and $\overrightarrow{ab} = \{x = \mu a + (1-\mu)b\colon \mu \leqq 1\}$. The distance between any two points x, $y \in U$, denoted by $d(x, y)$, is the measure of the angle formed by $\overrightarrow{\theta x}$ and $\overrightarrow{\theta y}$. The family of all convex compact sets having θ as an interior point is denoted by $\mathcal{K}$ and if r and R are two positive numbers, $\mathcal{K}_r = \{K \in \mathcal{K}\colon rB \subset K\}$, $\mathcal{K}^R = \{K \in \mathcal{K}\colon RB \supset K\}$ and $\mathcal{K}_r^R = \mathcal{K}_r \cap \mathcal{K}^R$.

The *radial function* of $K \in \mathcal{K}$ is the function $\rho_K\colon U \to R^+$ defined by $\rho_K(x) = \|(\overrightarrow{\theta x} \cap \text{bdry } K)\|$.

THEOREM 1. *If ρ is the radial function of $K \in \mathcal{K}_r^R$ and $k = R((R/r)^2 - 1)^{1/2}$ then for all x_1, $x_2 \in U$, $|\rho(x_1) - \rho(x_2)| \leqq k d(x_1, x_2)$. Furthermore, k is the best Lipschitz constant valid for the radial functions of all the members of $\mathcal{K}_r^R$.*

Proof. Let x_1, $x_2 \in U$ and assume $\rho(x_2) \leqq \rho(x_1) = \rho_1$. The point $p_1 = \rho_1 x_1$ clearly belongs to K, whence the set $D_{\rho_1} = \text{conv}(rB \cup \{p_1\})$ is contained in K. Hence, if ρ' denotes the radial function of D_{ρ_1} then $\forall y \in U\ \rho(y) \geqq \rho'(y)$ and by construction $\rho(x_1) = \rho'(x_1)$. If $\alpha_0 = \arccos(r/\rho_1)$ and $d(x_1, y) = \alpha$, then

$$\rho'(y) = \begin{cases} r & \text{if } \alpha \geqq \alpha_0 \\ r/\cos(\alpha_0 - \alpha) & \text{if } \alpha < \alpha_0. \end{cases}$$

If $d(x_1, x_2) > \alpha_0$ let x_3 be a point of U between x_1 and x_2 such that $d(x_1, x_3) = \alpha_0$; if $d(x_1, x_2) \leqq \alpha_0$ let $x_3 = x_2$. Then, if $\beta = d(x_1, x_3)$

$$\Delta(x_3) = \frac{\rho'(x_1) - \rho'(x_3)}{d(x_1, x_3)} = \frac{\rho_1 - (r/\cos(\alpha_0 - \beta))}{\beta} = \frac{\rho_1 \cos(\alpha_0 - \beta) - r}{\beta \cos(\alpha_0 - \beta)}.$$

It is easy to see that $\Delta(x_3)$ increases as x_3 tends to x_1. An elementary computation shows that $k(\rho_1) = \lim_{x_3 \to x_1} \Delta(x_3) = \rho_1((\rho_1/r)^2 - 1)^{1/2}$. From the previous considerations it follows that

$$\frac{\rho(x_1) - \rho(x_2)}{d(x_1, x_2)} \leqq \frac{\rho'(x_1) - \rho'(x_2)}{d(x_1, x_2)} \leqq \frac{\rho'(x_1) - \rho'(x_3)}{d(x_1, x_3)} = \Delta(x_3) \leqq k(\rho_1).$$

Finally, since $\rho_1 \leqq R$ then $k(\rho_1) \leqq k(R) = k$ and the theorem follows. To see that k is the best constant, consider a point x with $\|x\| = R$ and the set $D_R = \text{conv}(rB \cup \{x\})$. Then $D_R \in \mathcal{K}_r^R$ and admits no smaller constant.

If S is a nonempty set, a *convex component* of S is a maximal convex subset of S. The *kernel* of S is the set $\ker S = \{x \in S\colon \forall y \in S\ [x, y] \subset S\}$. The set S is *star-shaped* iff $\ker S \neq \varnothing$. We define $\mathcal{S}$ as the family of all compact star-shaped sets having θ as interior point of its kernels. If R and r are two positive numbers

then

$$\mathcal{S}_r = \{S \in \mathcal{S} : rB \subset S\}, \qquad \mathcal{S}^R = \{S \in \mathcal{S} : RB \supset S\} \quad \text{and} \quad \overset{R}{\mathcal{S}}_r = \mathcal{S}_r \cap \mathcal{S}^R.$$

It is clear that $\mathcal{K} \subset \mathcal{S}$. If $S \in \mathcal{S}$, $\forall x \in U$ the set $(\overrightarrow{\theta x} \cap \text{bdry } S)$ consists of a single point; hence the radial function of S is well defined.

LEMMA. *The set* ker S *is the intersection of all the convex components of* S.

Proof. Let $\{K_\lambda\}_{\lambda \in L}$ be the family of convex components of S, and $K_0 = \bigcap_{\lambda \in L} K_\lambda$. From the maximal principle it follows that $S = \bigcup_{\lambda \in L} K_\lambda$. Let $x \in K_0$; then $\forall y \in S$ $\exists \lambda \in L$ such that $y \in K_\lambda$ and $[x, y] \subset K_\lambda \subset S$; hence $x \in \ker S$ and $K_0 \subset \ker S$. Conversely, let $z \in \ker S$ and K_λ be a convex component of S. Set $K'_\lambda = \bigcup_{t \in K_\lambda} [z, t]$; then K'_λ is convex, and furthermore $K_\lambda \subset K'_\lambda \subset S$. So, by the maximality of K_λ, $K'_\lambda = K_\lambda$ and $z \in K_\lambda$. Since this is true for every $\lambda \in L$, $z \in K_0$ and $K_0 = \ker S$.

COROLLARY: ker S *is convex.*

THEOREM 2. *If* ρ *is the radial function of* $S \in \mathcal{S}_r^R$ *and* $k = R((R/r)^2 - 1)^{1/2}$ *then* $\forall x_1, x_2 \in U \, |\rho(x_1) - \rho(x_2)| \leq k d(x_1, x_2)$, *and this is the best Lipschitz constant valid for all the members of* $\mathcal{S}_r^R$.

Proof. Let $\{K_\lambda\}_{\lambda \in L}$ be the family of all convex components of S. Clearly $S \in \mathcal{S}_r^R$ implies $K_\lambda \in \mathcal{K}_r^R \forall \lambda \in L$ and, since $\rho(x) = \max_\lambda \rho_\lambda(x)$ where ρ_λ is the radial function of K_λ, the result follows immediately from Theorem 1. The example in Theorem 1 shows that k is the best Lipschitz constant valid for all the members of $\mathcal{S}_r^R$.

This work has been done under a fellowship of the Consejo Nacional de Investigaciones Cientificas y Técnicas de la Argentina.

ON COUNTABLY COMPACT NONLOCALLY COMPACT SPACES

T. B. RUSHING, Wake Forest College, (Now at the University of Georgia)

The purpose of this note is to establish the existence of countably compact nonlocally compact spaces, to give general methods for constructing such spaces, and to consider properties which they may or may not enjoy. A nonlocally compact space certainly must be noncompact and one can easily find examples of countably compact noncompact spaces in the literature covering lower spaces (e.g. the long line, see [1] p. 55); however, these seem invariably to be locally compact.

A topological space X is said to be *countably compact* if and only if every infinite subset of X has at least one limit point in X. We will call the space X

locally compact if and only if each point of X is contained in a compact neighborhood. (Our results would not be as general if we defined a space to be locally compact when each point of the space is contained in a neighborhood whose closure is compact.) A subcollection of a base $\mathfrak{B}$ for the topology of the space X is called a *distinguished collection* relative to $\mathfrak{B}$ if and only if each set of the collection contains at least one point of X not in any other element of $\mathfrak{B}$.

THEOREM 1. *If a countably compact space $(X, \mathfrak{I})$ has an uncountable distinguished collection relative to a base $\mathfrak{B}$, then the space $(X, \mathfrak{I}^*)$, where B^* is an element of the base $\mathfrak{B}^*$ of $\mathfrak{I}^*$ if and only if B^* can be expressed as the union of all but a denumerable number of elements of $\mathfrak{B}$, is countably compact but not locally compact.*

(The reader can prove that $\mathfrak{I}^*$ is the collection of all sets which are the union of all but a countable number of elements of $\mathfrak{B}$.)

Proof. (1) We will first show that $\mathfrak{B}^*$ is a base for a topology of X. Clearly, $\bigcup\{B^*: B^*\in\mathfrak{B}^*\}$ covers X. Let B_1^* and B_2^* be any two elements of $\mathfrak{B}^*$. We can find subcollections $\{B_\lambda\}$ and $\{B_\eta\}$ of $\mathfrak{B}$ such that $B_1^*=\bigcup_\lambda B_\lambda$ and $B_2^*=\bigcup_\eta B_\eta$ and such that $\mathfrak{B}\setminus\{B_\lambda\}$ and $\mathfrak{B}\setminus\{B_\eta\}$ are denumerable. Then $(\mathfrak{B}\setminus\{B_\lambda\})\cup(\mathfrak{B}\setminus\{B_\eta\})$ is denumerable and each element of $\mathfrak{B}\setminus[(\mathfrak{B}\setminus\{B_\lambda\})\cup(\mathfrak{B}\setminus\{B_\eta\})]=\{B_\lambda\}\cap\{B_\eta\}$ is contained in $B_1^*\cap B_2^*$. Now let x be any point of $B_1^*\cap B_2^*$. Then x is in some element B_1 of $\{B_\lambda\}$ and x is in some B_2 of $\{B_\eta\}$. Thus, $B_1\cap B_2$ is a member of $\mathfrak{I}$ which contains x. It follows that there is an element B_x of $\mathfrak{B}$ containing x and contained in $B_1\cap B_2$; hence, contained in $B_1^*\cap B_2^*$. Consider the collection $(\{B_\lambda\}\cap\{B_\eta\})\cup\{B_x\}$. The complement of this collection with respect to $\mathfrak{B}$ is denumerable; therefore, the union of all members of this collection is an element of $\mathfrak{B}^*$ which contains x and is contained in $B_1^*\cap B_2^*$ as desired.

(2) Next we will show that $(X, \mathfrak{I}^*)$ is countably compact. Let E be any infinite subset of X. Since $(X, \mathfrak{I})$ is countably compact there is an $x\in X$ such that every open set of $\mathfrak{I}$ which contains x also contains a point of E not x. In particular, every $B\in\mathfrak{B}$ which contains x has this property. Since each element of $\mathfrak{I}^*$ is a union of elements of $\mathfrak{B}$, it follows that every element of $\mathfrak{I}^*$ which contains x contains a point of E not x. Hence, x is also a limit point of E in the space $(X, \mathfrak{I}^*)$. (Notice here that Theorem 1 would still hold even if we had chosen the common, more restrictive, definition of countable compactness.)

(3) We conclude the proof by showing that $(X, \mathfrak{I}^*)$ is not locally compact. Let x be any point of X and let N^* be any neighborhood of $(X, \mathfrak{I}^*)$ which contains x. Then N^* contains an open set T^* of $(X, \mathfrak{I}^*)$. We know that T^* is a union of a subset of $\mathfrak{B}^*$, denoted by $\{B_\lambda^*\}$. Since each member of $\{B_\lambda^*\}$ can be expressed as the union of all but a denumerable number of elements of $\mathfrak{B}$, it follows that T^* can be expressed as the union of all but a countable number of elements of $\mathfrak{B}$. By hypothesis, $(X, \mathfrak{I})$ contains an uncountable distinguished collection relative to $\mathfrak{B}$; hence, T^* also contains an uncountable distinguished collection relative to $\mathfrak{B}$. Therefore, T^* contains a denumerable distinguished collection, $\{B_n\}$, $n=1, 2, \cdots$. Now let $\{B_\rho\}$ denote the collection of all elements of $\mathfrak{B}$ not in $\{B_n\}$, i.e., $\{B_\rho\}=\mathfrak{B}\setminus\{B_n\}$. Clearly, the collection $\{B_n^*\}$, $n=1, 2, \cdots$, where $B_n^*=\{\bigcup_\rho B_\rho\}\cup B_n$, is an open covering of N^*. Furthermore, no finite sub-

collection of $\{B_n^*\}$ will cover N^* since if B_n^* is removed from the collection then no member of the remaining collection will contain the element(s) of B_n which is (are) not in any other element of $\mathcal{B}$. This completes the proof of the theorem.

We know that no countably compact non-locally compact space can be both T_1 and second axiom since countable compactness implies local compactness in such spaces. However, one may prove that any space which satisfies the hypotheses of Theorem 1 (countably compact with an uncountable distinguished collection) is not T_0; hence, no countably compact non-locally compact space generated by use of Theorem 1 will be T_0. In addition, one may prove that no such generated space is first axiom. Obviously $(X, \mathfrak{I}^*)$ is connected.

Let us now consider two examples of spaces which may be employed to obtain countably compact non-locally compact spaces by application of Theorem 1. In these examples we make use of the fact that an easy way to obtain a countably compact (non-T_0) space is to "split" all (or all but a finite number) of the points of an infinite space. Given a space X, by a space obtained through *splitting a subset* A of X we mean, any space homeomorphic to the space $(X\backslash A)\cup(A\times\{0, 1\})$ having open sets of the form $(G\backslash A)\cup(\{G\cap A\}\times\{0, 1\})$ where G is open in X. The entire base of the space of the first example is a distinguished collection; however, the entire base of the space of the second example is not. More important, both the space of the first example and the corresponding generated space are not separable; however, the space of the second example is separable from which it follows that the generated space is also separable (choose the rationals in X as the countable collection).

EXAMPLE 1. Let X be the set of real numbers and let the base $\mathcal{B}$ for the topology $\mathfrak{I}$ of $(X, \mathfrak{I})$ be defined as follows: $\{0\}\in\mathcal{B}$ and given $x\neq 0$, the set $\{x, -x\}$ is an element of $\mathcal{B}$.

EXAMPLE 2. Let X be the following set of real numbers: $[0, 1]\cup[2, 3]$. Let a base $\mathcal{B}$ for $\mathfrak{I}$ be defined as follows: (1) Given any open interval (a, b), $\{\text{all rationals in } (a, b)\cap[0, 1]\}\cup\{\text{all rationals in } (a+2, b+2)\cap[2, 3]\}$ is a member of $\mathcal{B}$. (2) Let $c>0$ be a fixed real number. Then given any irrational number x in $[0, 1]$, $\{x\}\cup\{x+2\}\cup\{\text{all rationals in } (x-c, x+c)\cap[0, 1]\}\cup\{\text{all rationals in } (x-c+2, x+c+2)\cap[2, 3]\}$ is an element of $\mathcal{B}$.

REMARK. One can define *splitting a subspace* of a given space in a fashion analogous to our definition of splitting a subset (i.e., split the portion of each open set lying on the subspace), and observe for instance that any space obtained by splitting a nonempty, proper, closed (as a subset) subspace of a connected n-manifold without boundary is a locally n-Euclidean non-T_2 space.

Whereas Theorem 1 gives a method for obtaining a countably compact nonlocally compact space when given a particular type of countably compact space, the following easily proved theorem provides a method for obtaining such a space when given any nonlocally compact space.

THEOREM 2. *If X is a nonlocally compact space, then any space X^* obtained by splitting all but a finite number of the points of X is countably compact but not locally compact.*

Although any space generated by Theorem 2 will be non-T_0, the following generated spaces are second axiom (hence separable and Lindelöf). Note that X^* of example 3 is not connected.

EXAMPLE 3. Let X be the rationals in $[0, 1]$. Then one X^* may be expressed as the set of rationals in $([0, 1]\cup[2, 3])$ with the topology induced by base elements of the form, $\{\text{all rationals in } (a, b)\cap[0, 1]\}\cup\{\text{all rationals in } (a+2, b+2)\cap[2, 3]\}$.

EXAMPLE 4. Let X be Hilbert space and form some X^*.

SEPARATION AXIOMS IN QUASI-UNIFORM SPACES

S. A. NAIMPALLY, Iowa State University

In a remarkable paper [1] Davis showed how indexed systems of neighborhoods can be introduced in general topological spaces. This enables one to compare the sizes of neighborhoods at different points in the space, as in metric spaces, and consequently concepts like Cauchy nets, completeness, etc. can be introduced in general topological spaces. Pervin [3] used a different construction to prove that every topological space has a quasi-uniformity (satisfying all the conditions of a uniformity except the symmetry condition) which induces its original topology. In this note necessary and sufficient conditions are given in order that a quasiuniform space be (a) R_0 or (b) regular.

We describe Pervin's construction briefly. Let (X, T) be a topological space with topology T. Let $G\in T$.

(i) Let $S_G=G\times G\cup((X-G)\times X)$. It is easily shown that

(ii) $S_G \circ S_G\subset S_G$.

(iii) $\Delta=\{(x, x)\,|\,x\in X\}\subset S_G$.

So $\{S_G\,|\,G\in T\}$ is a subbase for a quasi-uniformity $\mathfrak{U}$ for X satisfying the conditions (iv)–(vii).

(iv) For each $U\in\mathfrak{U}$, $\Delta\subset U$.

(v) For each U, $V\in\mathfrak{U}$, $U\cap V\in\mathfrak{U}$.

(vi) For each $U\in\mathfrak{U}$, there exists a $V\in\mathfrak{U}$, such that $V\circ V\subset U$.

(vii) For each $U\in\mathfrak{U}$, if $U\subset V$ then $V\in\mathfrak{U}$.

(viii) $G\in T$ iff for each $x\in G$, there exists a $U\in\mathfrak{U}$ such that $U[x]\subset G$.

It is interesting to compare Pervin's construction with that of Davis. In a quasi-uniformity "triangle-inequality" (vi) is always satisfied, while in an indexed system of neighborhoods a local "triangle-inequality" is satisfied only for regular spaces. A symmetry condition need not hold in the former but is satisfied in the latter for R_0-spaces.

DEFINITION. *(X, T) is an R_0-space iff for each $x \in G \in T$, $\{\bar{x}\} \subset G$,* [1].

1. THEOREM. *(X, T) is an R_0-space if and only if X has a quasi-uniformity $\mathfrak{U}$ satisfying*: (ix) *for each $U \in \mathfrak{U}$ and $x \in X$ there exists a symmetric $V \in \mathfrak{U}$ such that $V[x] \subset U[x]$.*

Proof. Let (X, T) be an R_0-space and let $U \in \mathfrak{U}$, $x \in X$. Let $G = U(x) \in T$. Let $V = G \times G \cup (X - \{\bar{x}\}) \times (X - \{\bar{x}\})$. Obviously V is symmetric and it is easy to show that $S_G \cap S_{X-\{\bar{x}\}} \subset V$. Hence, by (vii), $V \in \mathfrak{U}$ and $V[x] = G$.

On the other hand let $\mathfrak{U}$ satisfy (ix). Let $x \in G \in T$. Then by (viii) there exists a $U \in \mathfrak{U}$ such that $U[x] \subset G$ and by (ix) there exists a symmetric $V \in \mathfrak{U}$ such that $V[x] \subset U[x]$. If $y \in \{\bar{x}\}$ then $x \in V[y]$. Since V is symmetric, $y \in V[x] \subset G$. So $\{\bar{x}\} \subset G$ and (X, T) is R_0.

Proof of the following theorem is similar to the above and is used in [2].

2. THEOREM. *(X, T) is a regular space if and only if $\mathfrak{U}$ satisfies the following condition*: (x) *for each $U \in \mathfrak{U}$ and $x \in X$ there exists a symmetric $V \in \mathfrak{U}$ such that $V \circ V[x] \subset U[x]$.*

Proof. Let (X, T) be regular. Then for each $U \in \mathfrak{U}$ and $x \in X$ there exist open neighborhoods H, I of x such that $I \subset \bar{I} \subset H \subset \bar{H} \subset G = U[x]$. Let $W_1 = G \times G \cup (X - \bar{H}) \times (X - \bar{H})$, $W_2 = H \times H \cup (X - \bar{I}) \times (X - \bar{I})$. We can show that $W_1, W_2 \in \mathfrak{U}$ (for example $S_G \cap S_H \cap S_{X-\bar{H}} \subset W_1$). If $V = W_1 \cap W_2$ then V is symmetric and $V \circ V[x] = G$.

Conversely, let $\mathfrak{U}$ satisfy (x). Let $x \in G \in T$. Then by (viii) there exists a $U \in \mathfrak{U}$ such that $U[x] \subset G$ and by (x) there exists a symmetric V such that $V \circ V[x] \subset U[x]$. If $y \in \overline{V[x]}$ then there exists a $z \in V[x] \cap V[y]$. Hence $y \in V[z] \subset V \circ V[x] \subset U[x]$; $V[x] \subset G$ and (X, T) is regular.

The author is at present at the University of Alberta, Edmonton, Canada.

THE CONVOLUTION RING OF SEQUENCES

R. G. BUSCHMAN, SUNY at Buffalo

Recently Louis Brand [2] has discussed the imbedding of the convolution ring of complex valued sequences in a division algebra. The product in this ring is defined by

$$ab(n) = \sum_{k=0}^{n} a(k)b(n - k).$$

We will show that the division ring has a related representation.

Consider the set of complex valued, two sided infinite sequences which have only a finite number of nonzero terms of negative index. Such a sequence can be denoted by

$$a = \{\bar{0}, a(-N), \cdots, a(-1); a(0), \cdots, a(n), \cdots\}.$$

(The bar over the first or last subset of elements indicates repetition to the left or right, respectively.) A two-sided convolution of such sequences can be defined by

$$ab(n) = \sum_{k=-\infty}^{+\infty} a(k)b(n-k) = \sum_{k=-Na}^{n+Nb} a(k)b(n-k),$$

where from the latter form we note that the summation index on the convolution is of finite range. This also shows that the product sequence is in the set. If further we take

$$(a+b)(n) = a(n) + b(n)$$

for the sum, then it can be verified by methods similar to those of Brand [2] that we have a commutative ring with unity, I: $\{\bar{0}; 1, \bar{0}\}$. The proof that there are no divisors of zero carries through with merely a change of notation. This ring we denote by R'; the ring of Brand, by R.

To verify that R' is a division ring we first show that the shifting sequence $s = \{\bar{0}; 0, 1, \bar{0}\}$ has an inverse. Consider $as = I$ from which we obtain

$$\sum_{k=-Na}^{n-1} a(k)s(n-k) = 1 \quad \text{if } n = 0; = 0 \text{ otherwise},$$

which reduces to $a(n-1)s(1) = 1$ if $n = 0$; $= 0$ otherwise, since $s(n-k) = 0$ unless $n-k = 1$. Hence, as expected, we have

$$s^{-1}: \{\bar{0}, 1; \bar{0}\}$$

which is a unique element of R'. Since $s^{-r} = (s^{-1})^r = (s^r)^{-1}$ is also in R' and since every sequence except the zero sequence has a first nonzero component, we can write any sequence a in the form $a = s^r b$, where r is chosen so that $b(0)$ is the first nonzero component of b. This condition $b(0) \neq 0$ is necessary and sufficient for the existence of b^{-1} in R, hence in R'. Thus $a^{-1} = s^{-r}b^{-1}$ exists in R'. Let $a, b \in R \subset R'$ with $b \neq 0$ and consider the equation $bc = a$. If $b(0) \neq 0$ then there exists a unique solution $c \in R$, but in any case there exists a unique solution c in R'. Hence we can set up the isomorphism between the equivalence class (a/b) of pairs of elements of R and the element $c \in R'$.

Lothar Berg [1] has also considered an operational calculus of sequences. The product is defined differently, that is

$$(a \cdot b)(n) = \sum_{k=0}^{n-1} a(k)[b(n-k) - b(n-1-k)] + a(n)b(0),$$

where we use "$\cdot$" to distinguish multiplications. The form is equivalent in the following sense to that which we have been considering. Let

$$\sigma: \{\,;\bar{1}\}, \rho: \{n+1\} = \{\,;1, 2, 3, \cdots\}.$$

From these special sequences we have

$$a \cdot b = \sigma ab, \qquad ab = \rho \cdot a \cdot b,$$

so that the field of "operators" of Berg is also equivalent to the ring R'.

COMPLEMENTS IN FINITE GROUPS

J. D. DIXON, University of New South Wales, Australia

The object of this note is to give a new proof of a useful theorem of I. Schur. The original theorem of Schur was later generalized by H. Zassenhaus, who proved the following theorem.

Let G be a finite group, and let H be a normal Hall subgroup of G (i.e. the order $|H|$ of H is relatively prime to the index $|G: H|$ of H in G). Then:

(a) *There exists a subgroup K of G such that $G = HK$ and $H \cap K = 1$. (K is called a complement of H in G.)*

(b) *If L is also a complement of H in G, and either H or G/H is solvable, then L is conjugate to K in G.*

Schur proved (a) in the case that H is abelian, and Zassenhaus used an induction argument (based on Schur's result) to prove the general case, and he also proved the conjugacy condition (b). (See [1] pages 162–163.) Since Feit and Thompson have now proved the long-standing conjecture that all groups of odd order are solvable, and since either H or G/H has odd order (because H is a Hall subgroup), the conjugacy condition (b) always holds.

Zassenhaus' derivation of his theorem from Schur's result is quite easy (although ingenious), but the classical proof of Schur's theorem requires the machinery of Schreier's theory of group extensions. (For example, see [1], [2] or [3].) More recently in [4], H. Wielandt showed how Schur's result could be derived by calculations with monomial matrices. Here we shall give a proof of Zassenhaus' theorem in case H is abelian. This will include a proof of Schur's theorem which appears to be briefer and more elementary than any given to date, and uses only a minimum of knowledge of the monomial representation of groups. The key to the method is to use the conjugacy (b) to prove the existence (a).

$\cap DG^*$, we have $DP = SD \cap DG^* = DG^*$ and $D \cap P = 1$.

Thus P is a complement of D in DG^*.

Because of (ii), (iii) and (iv), we may apply (2) to the group DG^* to conclude that $c^{-1}Pc \subseteq G^*$ for some $c \in D$. Then $c^{-1}Pc$ is clearly a complement of A^* in G^*. Because of the isomorphism between G and G^*, it follows that A has a complement in G.

Note. Instead of the properties of the monomial representation which we used here, we could have used the "universal embedding theorem" of the wreath product. (For example, see [5] Theorem 3.5.) It is possible to give a similar proof of the theorem of Gaschütz quoted in [4]. (Part of this is proved in [2] page 246.) I plan to give more general results in a later paper.

Added in Proof: The paper referred to will appear in Proc. London Math. Soc., (3) 17 (1967). It is titled "Complements of normal subgroups in infinite groups."

A NOTE ON EQUILATERAL METRIC TRIPLES

B. W. Huff and W. A. Kirk, University of California, Riverside

Let M denote a metric space and $S(a, b)$ a metric segment of M with endpoints a, b. A point f of $S(a, b)$ is said to be a *foot* of $p \in M$ on $S(a, b)$ if $pf = \inf[px: x \in S(a, b)]$. The following result is found in Blumenthal [1, p. 47].

(1) *If f is a foot of p on $S(a, b)$ and if* $\min[af, bf] > 3pf > 0$, *then there exist points q and r of $S(a, b)$ such that p, q, r form an equilateral triple* ($pq = qr = pr$).

This observation is used to characterize the metric segment among all closed, compact and convex metric spaces (which contain at least two points) by the absence of equilateral triples [1, p. 48]. (Also, see Blumenthal and Robinson [2]).

It is natural to ask whether 3 is the smallest multiplier of pf for which (1) is valid. In this note we sharpen (1) by showing that the number 3 of (1) may be replaced by 2 in general (i.e., if f is merely assumed to be any point of $S(a, b)$), and by 1 if f is a foot of p on $S(a, b)$. These numbers are the best possible.

Our terminology is that of [1].

Theorem 1. *If f is a foot of p on $S(a, b)$ and if*

$$\min[af, bf] \geq pf > 0,$$

then there exist points q, r of $S(a, b)$ such that p, q, r form an equilateral triple.

Proof. The segment $S(a, b)$ is isometric with a real line segment of length ab,

so we introduce coordinates in $S(a, b)$ in the obvious way, taking f to be the origin. Letters denoting points of $S(a, b)$ will also be interpreted as numbers, and we suppose $a<0$ and $b>0$. However, the symbol xy will denote the distance $|x-y|$ for $x, y\in S(a, b)$.

For $x\in[a, 0]$, let $F(x)=px$. Since $bf\geqq pf$, it is easily seen that there is a unique point $y(x)\in[x, b]$ such that $xy(x)=px$. Let $S(x)=y(x)p$. Since f is a foot of p on $S(a, b)$ we have

$$(*) \qquad F(0) = pf \leqq S(0).$$

Let x_0 be the point of $[a, 0]$ such that $x_0f=pf$, and let $y_0=y(x_0)$. There are two cases to consider.

Case 1. Suppose $y_0\in[0, b]$. Then

$$S(x_0) = py_0 \leqq pf + fy_0 = x_0f + fy_0 = x_0y_0 = x_0p = F(x_0).$$

This, together with (*) and the fact that both $F(x)$ and $S(x)$ are continuous, implies there is a point $X\in[a, 0]$ such that $F(X)=S(X)$. Then X, $y(X)$, p form an equilateral triple.

Case 2. If $y_0\notin[0, b]$ then, since $y(x)$ is a continuous function of x, and $y(x_0)<0$ while $y(0)=pf>0$, there is a point $X\in[x_0, 0]$ such that $y(X)=0$. Hence

$$S(X) = pf \leqq Xp = F(X).$$

The conclusion again follows as in Case 1.

THEOREM 2. *If f is any point of $S(a, b)$ such that* $\min[af, bf]\geqq 2pf$ *and if p is not on $S(a, b)$, then there exist points q, r of $S(a, b)$ such that p, q, r form an equilateral triple.*

Proof. For convenience we assume coordinates have been introduced and the metric "normalized" so that $S(a, b)\supseteq[0, 4]$, $f=2$ and $pf=1$. We may also assume that a foot f_p of p on $[0, 4]$ is in $[0, 2]$. (There is such a foot either in $[0, 2]$ or $[2, 4]$, cf. [1, p. 46].)

For $x\in[0, 2]$, let $F(x)=px$. A simple application of the triangle inequality yields a unique point $y(x)$ in $[x, 4]$ such that $xy(x)=F(x)$. Let $py(x)=K(x)$.

$F(0)=1+\eta$, $\eta\geqq 0$, since by the triangle inequality $pf+F(0)=1+F(0)\geqq 2$.

If $F(0)\geqq K(0)$ then, since $F(f_p)\leqq K(f_p)$, there is a number $X\in[0, f_p]$ such that $F(X)=K(X)$, and we reach the desired conclusion.

Suppose $F(0)<K(0)$. Let $G(x)=x+px$. Then $K(0)>1+\eta$ while $G(0)=1+\eta$. By the triangle inequality, $F(1)+\eta\geqq K(0)>1+\eta$. Thus $F(1)>1$, say $F(1)=1+\xi$, $\xi>0$. This implies

$$G(1) = 1 + F(1) = 2 + \xi$$

and therefore, again using the triangle inequality,

$$K(1) \leqq F(2) + \xi = 1 + \xi = F(1).$$

As before, since $F(0) \leqq K(0)$, there is a point $X \in [0, 1]$ such that $F(X) = K(X)$, and the proof is completed.

It might be noted that if $(p) + S(a, b) \subset E_2$, Theorem 1 is valid for the multiplier $1/\sqrt{3}$ (which is *less* than 1). In general, however, 1 is the smallest multiplier of pf for which Theorem 1 is valid. This can be seen by considering the Minkowski space $M_2^{(1)}$. The elements of this space are ordered pairs of real numbers with distance of $x = (x_1, x_2)$ and $y = (y_1, y_2)$ taken as

$$xy = |x_1 - y_1| + |x_2 - y_2| .$$

Let $S(a, b)$ be contained in the interval joining $(-1, 0)$ and $(1, 0)$ and let $p = (0, 1)$. It is easily seen that if p, x, y form an equilateral triple with x, $y \in S(a, b)$ then x and y *must* be the points $(-1, 0)$ and $(1, 0)$. Hence $S(a, b)$ is the interval joining these two points; the foot f of p on $S(a, b)$ is the origin, and $\min[af, bf] = pf$.

A slightly more complicated example can be given, also in the $M_2^{(1)}$, which shows that 2 is the smallest multiplier of pf for which Theorem 2 is valid.

The research of B. W. Huff was supported in part by the U. S. Army Research Office, Grant No. DA-ARO(D)-31-124-G383.

LOCATION OF THE ZEROS OF POLYNOMIALS

Q. G. Mohammad, Jammu and Kashmir University, India

The following theorem is due to Montel and Marty [1, p. 107].

Theorem A. *All the zeros of the polynomial*

$$p(z) = a_0 + a_1 z + \cdots + a_{n-1} z^{n-1} + z^n$$

lie in $|z| \leqq \max(L, L^{1/n})$ *where* L *is the length of the polygonal line joining in succession the points* $0, a_0, a_1, \cdots, a_{n-1}, 1$; *i.e.*

$$L = |a_0| + |a_1 - a_0| + \cdots + |a_{n-1} - a_{n-2}| + |1 - a_{n-1}| .$$

We prove

Theorem 1. *All the zeros of the polynomial of Theorem A lie in* $|z| \leqq R = \max(L_p, L_p^{1/n})$ *where*

$$L_p = n^{1/q} \left(\sum_{i=0}^{n-1} |a_i|^p \right)^{1/p}, \quad p^{-1} + q^{-1} = 1.$$

The bound is sharp.

Proof. We have

$$(1)\quad |p(z)| \geqq |z|^n\left(1-\sum_{i=1}^{n}\frac{|a_{n-i}|}{|z|^i}\right) \geqq |z|^n\left\{1-n^{1/q}\left(\sum_{i=1}^{n}\frac{|a_{n-i}|^p}{|z|^{ip}}\right)^{1/p}\right\}.$$

If $L_p \geqq 1$, $\max(L_p, L_p^{1/n}) = L_p$. Let $|z| \geqq 1$. Then $1/|z|^{ip} \leqq 1/|z|^p$ $(i=1, 2, \cdots, n)$. Hence (1) implies that if $|z| > L_p$ then

$$|p(z)| \geqq |z|^n\left\{1-\frac{n^{1/q}}{|z|}\left(\sum_{i=0}^{n-1}|a_i|^p\right)^{1/p}\right\} = |z|^n\left(1-\frac{L_p}{|z|}\right) > 0.$$

Again if $L_p \leqq 1$, $\max(L_p, L_p^{1/n}) = L_p^{1/n}$. Let $|z| \leqq 1$. Then $1/|z|^{ip} \leqq 1/|z|^{np}$ $(i=1, 2, \cdots, n)$. Hence, by (1), if $|z| > L_p^{1/n}$ then

$$\begin{aligned}|p(z)| &\geqq |z|^n\left\{1-\frac{n^{1/q}}{|z|^n}\left(\sum_{i=1}^{n}|a_{n-i}|^p\right)^{1/p}\right\}\\ &= |z|^n\left\{1-\frac{n^{1/q}}{|z|^n}\left(\sum_{0}^{n-1}|a_i|^p\right)^{1/p}\right\}\\ &= |z|^n\left(1-\frac{L_p}{|z|^n}\right) > 0.\end{aligned}$$

Hence $p(z)$ does not vanish for $|z| > \max(L_p, L_p^{1/n})$ and the theorem follows. The limit in Theorem 1 is attained by

$$p(z) = z^n - \frac{1}{n}(z^{n-1} + z^{n-2} + \cdots + z + 1)$$

since

$$L_p = n^{1/q}\left(\sum_{0}^{n-1}\frac{1}{n^p}\right)^{1/p} = n^{1/q}\left(\frac{n}{n^p}\right)^{1/p} = \frac{n^{1/p}\cdot n^{1/q}}{n} = 1$$

and 1 is a zero of $p(z)$.

Letting $q \to \infty$, it follows that all the zeros of $p(z)$ lie in

$$(2)\qquad |z| \leqq \max(L_1, L_1^{1/n}) \quad \text{where } L_1 = \sum_{i=0}^{n-1}|a_i|.$$

Applying this result to $(1-z)p(z)$ we obtain the theorem of Montel and Marty mentioned above.

THEOREM 2. *If* $0 < a_{i-1} \leqq ka_i$, $k > 0$, *then all the zeros of* $P(z) = a_0 + a_1 z + \cdots + a_n z^n$ *lie in* $|z| \leqq \max(M, M^{1/n})$ *where*

$$M = \frac{(a_0 + a_1 + \cdots + a_{n-1})}{a_n}(k-1) + k.$$

Proof. Consider

$$F(z) = (k - z)P(z) = (k - z)(a_0 + a_1z + \cdots + a_nz^n)$$
$$= ka_0 + (ka_1 - a_0)z + (ka_2 - a_1)z^2 + \cdots + (ka_n - a_{n-1})z^n - a_nz^{n+1}.$$

Applying (2) to the polynomial $F(z)/a_n$ we find that

$$L_1 = \frac{\sum_{i=0}^{n} |ka_i - a_{i-1}|}{a_n} = \frac{k(a_0 + a_1 + \cdots + a_n) - (a_0 + a_1 + \cdots + a_{n-1})}{a_n}$$
$$= \frac{(k - 1)(a_0 + a_1 + \cdots + a_{n-1})}{a_n} + k = M$$

and the theorem follows. Putting $k=1$ in Theorem 2 we get the following result due to Kakeya [1, p. 106].

THEOREM B. *If* $0<a_0\leqq a_1\leqq \cdots \leqq a_n$, *then all the zeros of the polynomial* $a_0+a_1z+a_2z^2+ \cdots +a_nz^n$ *lie in* $|z| \leqq 1$.

This follows from the fact that $M=1$, hence $\max(M, M^{1/n})=1$.

A NOTE CONCERNING FERMAT'S CONJECTURE

W. E. CHRISTILLES, St. Mary's University, San Antonio, Texas

This paper introduces some elementary results related to the famous unsolved conjecture of Fermat, that there exists no nontrivial solution in integers of the equation

$$x^n + y^n + z^n = 0 \tag{1}$$

for n an odd integer >2. It is sufficient to consider the equation

$$x^p + y^p + z^p = 0, \tag{2}$$

for p an odd prime. Theorem 2 (below) is a new proof of Stone's Theorem 1 [1]. In addition an extension of Stone's Theorem will be stated and proven.

Assume that equation (2) has a solution $x=a$, $y=b$, $z=c$. The following restrictions result in no loss of generality.

(3.1) $abc \neq 0$

(3.2) $|abc| \neq 1$

(3.3) $|a|$ and $|b|$ are not both unity.

(3.4) $(a, b,) = 1$, $(a, c) = 1$, and $(b, c) = 1$.

(3.5) $c < 0 < a < b < |c|$.

The first restriction excludes the trivial case. The restriction that $|abc| \neq 1$ is permissible since if $|abc| = 1$, with p an odd prime, then $a^p+b^p+c^p \neq 0$, a contradiction. If $|a|$ and $|b|$ are both unity, with p an odd prime and c a nonzero integer (see Restriction 3.1), then a, b, c is not a solution of equation (2). Hence the case in which $|a|$ and $|b|$ are both unity can be excluded. Moreover, if any two of a, b, and c have a common nonunit factor, then all of a, b, and c must contain the common factor. The common factor can be removed, resulting in the restrictions on a, b, and c that $(a, b) = 1$, $(a, c) = 1$, and $(b, c) = 1$. Finally, with p an odd prime and a, b, and c integers satisfying the first four restrictions, a, b, and c can be chosen such that $c < 0 < a < b < |c|$.

THEOREM 1. *Let a, b, c be integers satisfying restrictions* (3.1) *through* (3.5). *Then equation* (2) *has a solution if, and only if,*

$$x^{3p} + y^{3p} + z^{3p} - 3x^p y^p z^p = 0, \tag{4}$$

has a solution.

Proof. Consider the following identity:

$$x^{3p}+y^{3p}+z^{3p}-3x^p y^p z^p = (x^p+y^p+z^p)(x^{2p}+y^{2p}+z^{2p}-x^p y^p-x^p z^p-y^p z^p). \tag{5}$$

If $a^p+b^p+c^p=0$, then $a^{3p}+b^{3p}+c^{3p}-3a^p b^p c^p=0$. Conversely, suppose that $a^{3p}+b^{3p}+c^{3p}-3a^p b^p c^p=0$. Then either

$$a^p + b^p + c^p = 0 \quad \text{or} \quad a^{2p} + b^{2p} + c^{2p} - a^p b^p - a^p c^p - b^p c^p = 0. \tag{6}$$

But $a^{2p}>0$, $b^{2p}>0$, and $c^{2p}>0$. Moreover, due to restrictions (3.1) through (3.5) $c^{2p} > a^p b^p > 0$, $-a^p c^p > 0$, and $-b^p c^p > 0$. Thus the second equation in (6) is impossible. Hence $a^p+b^p+c^p=0$. This completes the proof of Theorem 1.

THEOREM 2. (Stone's Theorem, [1]). *Let a, b, c, and p be integers satisfying restrictions* (3.1) *through* (3.5), *with both p and $2p+1$ odd primes, and such that* $(abc, 2p+1) = 1$. *Then equation* (2) *has no solution.*

Proof. By Theorem 1, (2) has a nontrivial solution only if there exists a solution of (4), satisfying restrictions (3.1) through (3.5). Since $(abc, 2p+1) = 1$, (4) implies the congruence

$$a^{3p} + b^{3p} + c^{3p} - 3^p a^p c^p \equiv a^p + b^p + c^p - 3a^p b^p c^p \equiv -3a^p b^p c^p \equiv 0 \pmod{2p+1}.$$

But this is impossible since $(3abc, 2p+1) = 1$. This contradiction completes the proof of Theorem 2.

THEOREM 3. *Let a, b, c, and p be integers with p an odd prime, satisfying restrictions* (3.1) *through* (3.5). *Equation* (2) *has a solution only if*

$$x^{5p} + y^{5p} + z^{5p} - 5(x^p y^p z^p)(z^{2p} - x^p y^p) = 0 \tag{7}$$

has a solution.

Proof. Assume that (2) has a solution $x=a$, $y=b$, and $z=c$ satisfying restrictions 3.1 through 3.5. Transposing c^p, (in $a^p+b^p+c^p=0$) to the right side of the equation, raising both sides of the resulting equation to the fifth power, and simplifying yields

$$a^{5p} + b^{5p} + c^{5p} + 5a^pb^p[a^{3p} + b^{3p} + 2a^pb^p(a^p + b^p)] = 0. \tag{8}$$

Since $a^p+b^p=-c^p$, (8) can be written as

$$a^{5p} + b^{5p} + c^{5p} + 5a^pb^p[a^{3p} + b^{3p} - 3a^pb^pc^p + a^pb^pc^p] = 0. \tag{9}$$

But, due to Theorem 1, $a^p+b^p+c^p=0$ if and only if $a^{3p}+b^{3p}-3a^pb^pc^p=-c^{3p}$. Substituting $a^{3p}+b^{3p}-3a^pb^pc^p=-c^{3p}$ into (9) and simplifying results in (7)

$$a^{5p} + b^{5p} + c^{5p} - 5a^pb^pc^p(c^{2p} - a^pb^p) = 0.$$

Hence, with the stipulation that restrictions (3.1) through (3.5) apply, (2) implies (7). This completes the proof of Theorem 3.

THEOREM 4. *Let a, b, c, and p be integers satisfying restrictions* (3.1) *through* (3.5), *with both p and $4p+1$ odd primes, and such that* $(abc, 4p+1)=1$. *Then equation* (2) *has no solution.*

Proof. From Theorem 3, (2) has a solution only if there exists a solution of (7) which satisfies restrictions (3.1) through (3.5). Since $(abc, 4p+1)=1$, (7) implies the congruence

$$\begin{aligned} a^{5p} + b^{5p} + c^{5p} - 5(abc)^p(c^{2p} - a^pb^p) &\equiv a^p + b^p + c^p - 5(abc)^p(c^{2p} - a^pb^p) \\ &\equiv -5(abc)^p(c^{2p} - a^pb^p) \equiv 0 \pmod{4p+1}. \end{aligned} \tag{10}$$

But $a^p+b^p+c^p=0$, implies that

$$2(c^{2p} - a^pb^p) = a^{2p} + b^{2p} + c^{2p}. \tag{11}$$

(This is easily seen upon transposing c^p, in $a^p+b^p+c^p=0$, to the right side, squaring both sides, adding c^{2p} to both sides, and simplifying.) Multiplying (10) by -2 and substituting (11) into (10) yields

$$-5(abc)^p(a^{2p} + b^{2p} + c^{2p}) \equiv -5(abc)^p(\pm 1 \pm 1 \pm 1) \equiv 0 \pmod{4p+1}. \tag{12}$$

Since $(abc, 4p+1)=1$, (12) can be reduced to

$$-5(\pm 1 \pm 1 \pm 1) \equiv 0 \pmod{4p+1}. \tag{13}$$

With the observation that (13) is not possible for any choice of signs, the proof of Theorem 4 is complete.

AN EXTENSION OF A THEOREM CONCERNING EQUILATERAL TRIPLES

L. M. BLUMENTHAL, University of Missouri

Introduction. A subset L of a metric space is a *metric line* provided there is a one-to-one, distance-preserving mapping of L onto a euclidean straight line. If M_1, M_2 are metric spaces, M_1 is *contained homothetically* in M_2 provided there exists a mapping f of M_1 into M_2, and a positive constant k, such that, for each two points p, q of M_1, the distance $f(p)f(q) = k \cdot pq$.

As a basis for a metric characterization of the euclidean straight line, it has been shown [1] that if a metric space contains a metric line L and a point p not on L, then the space contains an equilateral point-triple (i.e., points q, r, s with $qr = rs = qs \neq 0$). Later, that result was obtained by the writer [2] as a corollary of the following theorem: *If a metric space contains a metric segment $S_{a,b}$ with endpoints a, b, and a point p with a foot f_p in $S_{a,b}$ such that* $\min [af_p, bf_p] > 3 \cdot pf_p > 0$, *then the space contains an equilateral triple.*

We show that the first result mentioned in the preceding paragraph admits an interesting extension (which permits an extension of the metric characterization of the straight line to which the earlier result gave rise). But, on the other hand, the theorem concerning the metric segment $S_{a,b}$, and a point p not on it, *cannot be extended in that manner.*

1. The extension. The extended result is expressed in the following theorem.

THEOREM 1. *A metric space consisting of a metric line L and a point p, not on L, contains homothetically every metric point-triple.*

Proof. Let q, r, s denote any metric point-triple with $qr = a$, $rs = b$, $qs = c$ and $a \geqq b \geqq c > 0$. If q, r, s are linear, then $a = b + c$ and L contains points q', r', s' with $q'r' = qr$, $r's' = rs$, $q's' = qs$.

Suppose, now, that q, r, s are not linear, and consequently $a < b + c$. Since L is isometric with the euclidean straight line, the points of L may be represented by real numbers x with distance $xy = |x - y|$, where the number corresponding to a foot f_p of p on L is zero. (Coordinates serve also as labels.)

Put $S(x) = px$, $x \in L$, $x \geqq 0$, and write $S(0) = pf_p = d$. Clearly $S(x) \geqq d$ and, by the triangle inequality, $|x - S(x)| \leqq d$. Define, now, the positive-valued function $k(x)$ by the equation $S(x) = a \cdot k(x)$, and let $y(x) = x - b \cdot k(x)$, $T(x) = py(x)$, $x \geqq 0$. Then

$$d \leqq T(x) \leqq d + |x - b \cdot k(x)| = d + |x - (b/a)S(x)| .$$

Define the function $R(x)$, continuous for $x \geqq 0$, by

$$R(x) = T(x)/c - S(x)/a.$$

Since $0 \leqq |x - S(x)| \leqq d$, for $x \neq 0$, $0 \leqq |1 - S(x)/x| \leqq d/x$, and consequently $\lim_{x \to \infty} S(x)/x = 1$. Now

$$R(0) = T(0)/c - S(0)/a = T(0)/c - d/a \geqq 0,$$

since $T(0) \geqq d$ and $c \leqq a$.

Case 1. $R(0) = 0$. Then the pairwise distinct points p, 0, $y(0)$ are the desired triple since $\operatorname{dist}(p, 0) = S(0) = d$, $\operatorname{dist}(p, y(0)) = T(0)$, $\operatorname{dist}(0, y(0)) = b \cdot k(0) = b \cdot S(0)/a = bd/a$; that is,

$$\frac{\operatorname{dist}(p, 0)}{a} = \frac{\operatorname{dist}(0, y(0))}{b} = \frac{\operatorname{dist}(p, y(0))}{c} = k(0).$$

Since $\operatorname{dist}(p, 0) = d \leqq \operatorname{dist}(p, y(0))$ and $a \geqq b \geqq c$, the above equalities imply $\operatorname{dist}(p, 0) = \operatorname{dist}(0, y(0)) = \operatorname{dist}(p, y(0))$ and $a = b = c$. Thus if $R(0) = 0$, the given triangle is equilateral.

Case 2. $R(0) > 0$. Since $T(x) \leqq d + |x - (b/a)S(x)|$, it follows readily that

$$R(x) \leqq d/c + x\{a\,|\,1 - (b/a)S(x)/x\,| - c \cdot S(x)/x\}/ac$$

and, since $\lim_{x \to \infty} S(x)/x = 1$,

$$\lim_{x \to \infty} \{a\,|\,1 - (b/a)S(x)/x\,| - c \cdot S(x)/x\} = a - (b + c) < 0.$$

Hence $R(x) \to -\infty$ as $x \to \infty$ and, since $R(0) > 0$, it follows from the continuity of $R(x)$ that a value x_0 exists such that

$$R(x_0) = T(x_0)/c - S(x_0)/a = 0.$$

The points p, x_0, $y_0 = y(x_0)$ are the desired three points since clearly

$$\frac{px_0}{a} = \frac{x_0y_0}{b} = \frac{py_0}{c} = k(x_0);$$

that is, $px_0 = k(x_0) \cdot qr$, $x_0y_0 = k(x_0) \cdot rs$, $py_0 = k(x_0) \cdot qs$, with $k(x_0) > 0$.

COROLLARY. *A metric space is a metric line if and only if it contains at least one metric line, and there exists at least one metric point-triple that is not homothetically contained in the space.*

Since every complete, metrically convex and externally convex metric space (containing at least two distinct points) contains a metric line, the following new metric characterization of the line is obtained.

THEOREM 2. *A metric space is congruent with the euclidean straight line if and only if the space is complete, metrically convex and externally convex, contains at least two distinct points, and at least one metric triple is not homothetically contained in the space.*

We note that the analogue of Theorem 1 in the case of a metric segment $S_{a,b}$ and a point p, not on it, is *not* valid, no matter what demand is made upon the distances pf_p, af_p, bf_p, where f_p denotes a foot of p on $S_{a,b}$. For if $(p) + S_{a,b}$ is a subset of the euclidean plane, it is easily seen that an angle α $(0 < \alpha < \pi)$ exists such that α exceeds the maximum angle of any triangle with vertices p, x, y,

where x, y denote distinct points of $S_{a,b}$. Then evidently the set $(p)+S_{a,b}$ does not contain a point-triple that is homothetic to the vertices of a euclidean triangle, one of whose angles is α.

An extension of Theorem 1, in which the metric line L is replaced by euclidean n-space E_n and the metric point-triple by the vertices of an $(n+1)$-dimensional simplex, will be published elsewhere.

A LOWER BOUND FOR THE NUMBER OF VERTICES OF A GRAPH

M. E. Watkins, University of North Carolina at Chapel Hill

In this note we derive a lower bound for the number of vertices of a graph in terms of its diameter and connectivity. We then show that the inequality so obtained is the best possible result.

Let K_m denote the complete graph on m vertices. For other terminology, see Ore [1].

Theorem 1. *If G is a graph on n vertices with connectivity $\lambda \geqq 1$ and diameter $\delta \geqq 1$, then $n \geqq \lambda(\delta+1)-2$.*

Proof. There exist vertices u and v of G whose distance from each other is δ. Since the connectivity of G is λ, there exist at least λ arcs joining u and v having only the vertices u and v in common, by Whitney [2]. Each of these arcs contains at least $\delta-1$ vertices other than u and v. Hence, the union of these arcs contains at least $\lambda(\delta-1)+2$ vertices.

Theorem 2. *Given positive integers δ and λ, there exists a graph G on n vertices with diameter δ and connectivity λ such that $n=\lambda(\delta-1)+2$.*

Proof. Let $H_1, \cdots, H_{\delta-1}$ represent $\delta-1$ disjoint copies of K_λ. Form G as follows: join each vertex of H_i to each vertex of H_{i+1} by an edge $(i=1, \cdots, \delta-2)$; then join a new vertex u to each vertex of H_1 by an edge and similarly join a vertex v to each vertex of $H_{\delta-1}$. The resulting graph clearly satisfies the prescribed conditions.

ON THE RATIONAL SOLUTIONS OF $m^n = n^m$ WITH $m \neq n$

SOLOMON HURWITZ, City College, New York

This paper solves, in rational numbers, a problem which might be described as "commutative exponentiation." The subject is a Diophantine equation that has evoked considerable attention since the days of Euler (see [6, pp. 578–579], [7, pp. 150–151] and especially [2, p. 687]). And interest in

$$m^n = n^m \qquad (m \neq n) \tag{1}$$

still appears to be lively. Thus, equation (1) made an appearance on both the 1960 and 1961 Putnam Prize Competition [1(a), p. 633], [1(b), p. 762]. References [3, pp. 856–861] and [4, p. 571] deal with the solutions of (1) in algebraic numbers. Then there is Banach's result that (1) has infinitely many solutions in transfinite cardinals [5, p. 151] and Jacobsthal's Theorem [5, pp. 359–362] on the general solution in transfinite ordinal numbers.

1. We first consider positive rational solutions. We shall assume that $m > n$. If $n \leqq 1$, $m^n > n^n \geqq n^m$. In looking for solutions of $m^n = n^m$ we may therefore limit ourselves to the case $m > n > 1$.

Let $m = a/b$, $n = c/d$, $(a, b) = (c, d) = 1$, $a > b$, $c > d$, $ad > bc$. If $(a/b)^{c/d} = (c/d)^{a/b}$ then

$$a^{bc} = c^{ad} \quad \text{and} \quad b^{bc} = d^{ad}, \tag{2}$$

a and c must have the same primes in their canonical representation as products of powers of primes and so must b and d. In the case of a and c these are certainly not empty products. Let

$$\begin{aligned} a &= \Pi p_i^{\alpha_i}, & c &= \Pi p_i^{\gamma_i}, \\ b &= \Pi q_j^{\beta_j}. & d &= \Pi q_j^{\delta_j}. \end{aligned} \tag{3}$$

It follows from (2) that for each value of i, $\alpha_i bc = \gamma_i ad$, hence

$$\frac{\alpha_i}{\gamma_i} = \frac{ad}{bc} = \frac{\lambda}{\mu}$$

with $(\lambda, \mu) = 1$ and $\lambda > \mu$.

Let

$$\alpha_i = \lambda\rho_i, \quad \gamma_i = \mu\rho_i \quad \text{and} \quad \Pi p_i^{\rho_i} = r \tag{4}$$

then

$$a = r^\lambda, \quad c = r^\mu \quad \text{with} \quad r > 1, \quad \lambda > 1. \tag{5}$$

Similarly

$$b = s^\lambda, \quad d = s^\mu \quad \text{with} \quad s \geqq 1. \tag{6}$$

If $b=d=1$, $s=1$ and we choose λ and μ as in (5). Hence

$$\frac{\lambda}{\mu}=\frac{r^{\lambda}s^{\mu}}{r^{\mu}s^{\lambda}}=\frac{r^{\lambda-\mu}}{s^{\lambda-\mu}} \tag{7}$$

$$\lambda = r^{\lambda-\mu}, \quad \mu = s^{\lambda-\mu}$$

$$\lambda-\mu = r^{\lambda-\mu}-s^{\lambda-\mu}.$$

But (7) can hold only if $\lambda-\mu=1$. For, suppose that $\lambda-\mu>1$. Since $r>s$,

$$r^{\lambda-\mu} \geqq (s+1)^{\lambda-\mu} > s^{\lambda-\mu}+(\lambda-\mu)s^{\lambda-\mu-1},$$

since the expansion of $(s+1)^{\lambda-\mu}$ by the binomial theorem would contain more than two terms. It follows that $r^{\lambda-\mu}-s^{\lambda-\mu}>\lambda-\mu$.

Equation (7) can be satisfied only by letting $\lambda-\mu=1$ and $r-s=1$. This means that

$$a=(1+s)^{1+s}, \qquad c=(1+s)^{s},$$

$$b=s^{1+s}, \qquad d=s^{s},$$

and $m=(1+1/s)^{1+s}$, $n=(1+1/s)^{s}$ with $s\geqq 1$. We easily verify that these values for m and n satisfy $m^n=n^m$ if s is *any* positive integer.

2. We next consider rational solutions with m and n both negative, or, we consider the equation $(-u)^{-v}=(-v)^{-u}$ with $u>v>0$. Since $(-u)^{-v}$ does not necessarily have a real value we will study the equation in the complex plane where each side of the equation will generally be many valued. Is there any value of $(-u)^{-v}$ which will be the same as some value of $(-v)^{-u}$? This is equivalent to demanding that

$$e^{-v[\log u+k_1\pi i]} = e^{-u[\log v+k_2\pi i]}$$

where $\log u$ and $\log v$ are real, and k_1 and k_2 are odd integers, or

$$e^{-v\log u} = e^{-u\log v} \tag{8}$$

and

$$k_1v-k_2u=L \tag{9}$$

with L an even integer.

Equation (8) is equivalent to $u^v=v^u$. Hence

$$u=\left(\frac{s+1}{s}\right)^{1+s}, \qquad v=\left(\frac{s+1}{s}\right)^{S}$$

with s a positive integer. Substituting in (9) and multiplying both sides by s^{1+s}, we get

$$k_1s(s+1)^{s}-k_2(s+1)^{s+1}=Ls^{1+s}. \tag{10}$$

If s were *even* the left side of (10) would be an odd integer and the right side an

even integer. Hence, if s is even, no value of $(-u)^{-v}$ is equal to a value of $(-v)^{-u}$. If s is *odd* however, we shall show that for *every* odd k_1 we can find an odd k_2 and an even L so that (10) holds. For the congruence $x(s+1) \equiv k_1 \pmod{s^s}$ is solvable since $(s+1, s^s)=1$. If the integer x_1 satisfies the congruence so will x_1+s^s. Let k_2' be the odd integer of the pair x_1, x_1+s^s and let $k_2=k_2's$. Then

$$k_1 s - (k_2' s)(s+1) = L' s^{s+1}$$

and

$$k_1 s(s+1)^s - k_2(s+1) = [L'(s+1)^s] s^{1+s}$$

and $L=L'[s+1]^s$ is even. If s is odd therefore, *every* value of $(-u)^{-v}$ is a value of $(-v)^{-u}$. One of these values will be positive as we see by setting $k_1=s^s$.

3. Finally we consider rational solutions where m and n have opposite signs, or we consider the equation $u^{-v}=(-v)^u$ with $u>0$, $v>0$. We shall show that this equation has no solution in positive rationals. Taking absolute values of both members, we must have $u^v \cdot v^u = 1$. We may assume that $u>1>v$, and letting $u=a/b$, $v=c/d$ we get $a^{bc}=d^{ad}$ and proceeding as before $a=r^\lambda$, $d=r^\mu$, $b=s^\lambda$, $c=s^\mu$, $\lambda/\mu = r^{\lambda+\mu}/s^{\lambda+\mu}$, $\lambda = r^{\lambda+\mu}$. But $r^{\lambda+\mu} > 2^\lambda > \lambda$.

4. We have established the following theorem:

All the rational solutions of $m^n=n^m$ with $|m|>|n|$ are given by

$$(1) \qquad m = \left(1+\frac{1}{s}\right)^{1+s}, \qquad n = \left(1+\frac{1}{s}\right)^s$$

with s a positive integer, and

$$(2) \qquad m = -\left(1+\frac{1}{s}\right)^{1+s}, \qquad n = -\left(1+\frac{1}{s}\right)^s$$

with s a positive odd integer.

THE 2Ω PROPERTY OF TORSION-FREE ABELIAN GROUPS

R. C. ENTRINGER, University of New Mexico

A group G will be said to be a 2Ω-group if it has the following property: if A and B are finite nonempty subsets of G with $|A|+|B|\geq 3$, then there exist at least two g in G having a unique representation $g=a+b$, $a\in A$, $b\in B$. In other words at least two entries in the list of sums $a+b$, $a\in A$, $b\in B$ occur once only.

It is conjectured in [2] that every torsion-free group is a 2Ω-group. A similar conjecture appears in [3]. As remarked in [2], the theorem that all torsion-free abelian groups are 2Ω-groups follows immediately from the property [1] that all torsion-free abelian groups are ordered groups. It is also shown in [2] that the conjecture is true if in the definition of a 2Ω-group either A or B is required to be abelian but the proof again uses the order property of torsion-free abelian groups. The first mentioned theorem may be proved directly, however, without appeal to the axiom of choice. We prove the following equivalent form.

THEOREM. *If there exist two nonempty finite subsets A and B of an abelian group G such that $|A|+|B|\geq 3$ and, with at most one exception, each entry in the list of sums $a+b$, $a\in A$, $b\in B$ occurs at least twice, then G is not torsion-free.*

Proof. We choose notation so that $A=\{a_1, \cdots, a_n\}$, $n\geq 2$, and if some $a+b$ occurs once only in the list of sums then $a=a_n$.

For each a_i $(i=1, \cdots, n-1)$ we form a finite set of equations as follows. Choose any member b_{i1} of B. We may express $a_i+b_{i1}=a_{i2}+b_{i2}$ for some $b_{i2}\in B$, $b_{i2}\neq b_{i1}$. Then $a_i+b_{i2}=a_{i3}+b_{i3}$ for some $b_{i3}\in B$, $b_{i3}\neq b_{i2}$. Since B is finite we obtain a $b_{is}=b_{ir}$ for some $r<s$ after a finite number of repetitions of this process. If we now add the set of equations

$$\begin{aligned}
a_i + b_{ir} &= a_{i,r+1} + b_{i,r+1}\\
a_i + b_{i,r+1} &= a_{i,r+2} + b_{i,r+2}\\
&\cdots\cdots\cdots\cdots\\
a_i + b_{i,s-2} &= a_{i,s-1} + b_{i,s-1}\\
a_i + b_{i,s-1} &= a_{is} + b_{ir},
\end{aligned}$$

we obtain $(s-r)a_i=\sum_{j=1}^{s-r} a_{i,r+j}$. Since we may produce an equation of this form for each a_i $(i=1, \cdots, n-1)$ we obtain the system

$$\sum_{j=1}^{n} c_{ij}a_j = 0, \qquad i = 1, \cdots, n-1, \tag{1}$$

where

(i) $\sum_{j=1}^{n} c_{ij}=0$, $i=1, \cdots, n-1$

(ii) $c_{ij}\geq 0$, $i\neq j$

(iii) $c_{ii}<0$, $i=1, \cdots, n-1$.

We now show by induction on n that the existence of such a system implies the existence of an element of finite order in G.

If $n=2$ then (1) takes the form $c_{11}a_1+c_{12}a_2=0$, where $c_{11}=-c_{12}\neq 0$. Hence a_1-a_2 is of finite order. If $n>2$ then from (1) we may obtain the equivalent system

$$\sum_{j=1}^{n} c_{1j}a_j = 0, \qquad \sum_{j=1}^{n} (c_{i1}c_{1j} - c_{11}c_{ij})a_j = 0, \qquad i = 2, \cdots, n-1,$$

where upon setting $d_{ij}=c_{i1}c_{1j}-c_{11}c_{ij}$ the last $n-1$ equations form a system

$$\sum_{j=2}^{n} d_{ij}a_j = 0, \qquad i = 2, \cdots, n-1, \tag{1'}$$

where

(i') $\sum_{j=2}^{n} d_{ij}=0$, $i=2, \cdots, n-1$;

(ii') $d_{ij}\geqq 0$, $i\neq j$;

(iii') either (a) $d_{ii}<0$, $i=2, \cdots, n-1$ and by the induction assumption G contains an element of finite order, or (b) some $d_{kk}\geqq 0$ and hence by (i') and (ii'), $d_{kj}=0$ for $j=2, \cdots, n$.

Now $c_{k1}=0$ gives $d_{kk}=-c_{11}c_{kk}<0$ which is impossible and we may conclude that $c_{1j}=0$ for $j=2, \cdots, k-1, k+1, \cdots, n$. Thus from (i) and (iii) we have $c_{11}=-c_{1k}\neq 0$. In this case a_1-a_k is of finite order.

This completes the inductive step and the theorem follows.

The author wishes to thank the referee for his informative suggestions.

CLASSROOM NOTES

ON COWEN'S NOTE "AN ELEMENTARY FIXED POINT THEOREM"

J. G. BÁRON, Rye, New York

Cowen considers in [1] a figure formed by a closed plane curve, and a similar figure, reduced in size, placed inside the original figure. He gives an elementary proof of the existence of a fixed point. A shorter elementary proof of this theorem is given below, and it is shown that the fixed point can be constructed by straight-edge and compass.

Any given position of the smaller figure can be considered as a result of a certain similarity transformation of the plane. In such a transformation a line through any two points, and a line through the corresponding points form a constant angle, the angle of rotation of the transformation. It is shown in ele-

mentary coordinate geometry that a similarity transformation always has a fixed point. It is the center of rotation of the transformation from which any two corresponding points are seen under the angle of rotation of the transformation.

In order to complete the proof of the theorem one has to prove that, under the conditions of the problem, the fixed point is inside of the figures. Suppose that the fixed point Q were outside of the figures.

Draw from Q two tangents to the original curve with points of tangency A_1 and B_1 in such a way that all the other points of the figure should be inside of the angle A_1QB_1. Let A_2 and B_2 be the points corresponding to A_1 and B_1. Then $\sphericalangle A_1QA_2 = \sphericalangle B_1QB_2$ both in magnitude and in sense. In other words, rotation of A_1Q toward A_2Q about Q must have the same direction as rotation of B_1Q toward B_2Q. However, this would put the ray QB_2 outside of $\sphericalangle A_1QB_1$, and therefore B_2 outside of the original figure, contrary to the assumption of the problem.

In order to construct Q select any A_1 and B_1 points of the original figure and let A_2 and B_2 be their corresponding points. Suppose first that the lines through A_1B_1 and A_2B_2 are not parallel; let N be their point of intersection. Then $\sphericalangle A_1NA_2$, $\sphericalangle A_1QA_2$ and $\sphericalangle B_1QB_2$ are all equal to the angle of rotation. Therefore the circumcircles of triangles A_1NA_2 and B_1NB_2 must intersect (besides N) in Q. On the other hand, if $A_1B_1 \| A_2B_2$, then the angle of rotation is zero, the circumcircles become straight lines through A_1A_2 and B_1B_2, and Q is their intersection. The lines A_1A_2 and B_1B_2 necessarily intersect in this case; were they also parallel, then the two figures would be congruent, contrary to the assumption of the problem.

UNIQUENESS OF THE POLAR DECOMPOSITION

ALVIN HAUSNER, City College of New York

If τ is a non-singular linear operator on a finite dimensional complex inner-product space $\mathcal{S}$, then $\tau = \sigma\eta$ where σ is a positive definite (hermitian) operator and η is unitary. (We recall that a hermitian operator is called *positive definite* if all its eigenvalues are strictly positive numbers.) This so-called *polar decomposition* of τ is unique in the sense that $\sigma_1\eta_1 = \sigma_2\eta_2$, with positive definite σ_1, σ_2 and unitary η_1, η_2, implies $\sigma_1 = \sigma_2$ and $\eta_1 = \eta_2$. The existence of the polar decomposition is easily established by defining σ to be a positive definite square root of $\tau\tau^*$, i.e. $\sigma^2 = \tau\tau^*$, and by defining $\eta = \sigma^{-1}\tau$. The uniqueness of the decomposition is most often proved by showing that a positive definite operator has a unique positive definite square root (see [3, p. 169], [4, p. 279], [5, p. 188]. In [1, pp. 14–15] uniqueness is established by proving that the exponential of

a matrix gives a one-to-one mapping from the set of all hermitian matrices onto the set of all positive definite hermitian matrices.

In this note we present a new proof of the uniqueness of the polar decomposition. All we require is the existence of *at least one* positive definite square root of a positive definite operator. The latter fact is immediate from the diagonability of a given positive definite operator. We will denote by $\sigma^{1/2}$ a fixed positive definite square root of the positive definite operator σ.

As for the following lemma, compare the theorem and exercise in [2, p. 114].

LEMMA. *If σ_1 and σ_2 are positive definite operators on $\mathcal{S}$, then $\sigma_1\sigma_2$ has only positive eigenvalues.*

Proof. The operator $\sigma_1^{1/2}\sigma_2\sigma_1^{1/2}$ is evidently nonsingular and it is hermitian, for $(\sigma_1^{1/2}\sigma_2\sigma_1^{1/2})^* = (\sigma_1^{1/2})^*\sigma_2^*(\sigma_1^{1/2})^* = \sigma_1^{1/2}\sigma_2\sigma_1^{1/2}$. Further, for any non-zero vector X in $\mathcal{S}$, we have

$$(A) \qquad (\sigma_1^{1/2}\sigma_2\sigma_1^{1/2}X, X) = (\sigma_2(\sigma_1^{1/2}X), \sigma_1^{1/2}X) > 0$$

since $\sigma_1^{1/2}X \neq 0$ and σ_2 is positive definite. Thus, if $\sigma_1^{1/2}\sigma_2\sigma_1^{1/2}X_0 = aX_0$ for some scalar $a \neq 0$ and vector $X_0 \neq 0$ in $\mathcal{S}$, then

$$(\sigma_1^{1/2}\sigma_2\sigma_1^{1/2}X_0, X_0) = (aX_0, X_0) = a(X_0, X_0) > 0$$

by (A), and this means $a > 0$.

To complete the proof, observe that the eigenvalues of $\sigma_1\sigma_2$ are the same as those of $\sigma_1^{1/2}\sigma_2\sigma_1^{1/2}$, for $(\sigma_1^{1/2})^{-1}(\sigma_1\sigma_2)\sigma_1^{1/2} = \sigma_1^{1/2}\sigma_2\sigma_1^{1/2}$.

THEOREM. *If $\sigma_1\eta_1 = \sigma_2\eta_2$ with positive definite σ_1, σ_2 and unitary η_1, η_2, then $\sigma_1 = \sigma_2$ and $\eta_1 = \eta_2$.*

Proof. The lemma applies to $\sigma_2^{-1}\sigma_1$ which thus has positive eigenvalues. The operator $\eta_2\eta_1^{-1}$ is a unitary map and hence all its eigenvalues have unit modulus. Since $\eta_2\eta_1^{-1} = \sigma_2^{-1}\sigma_1$, the eigenvalues of $\eta_2\eta_1^{-1}$ are all positive and therefore $\eta_2\eta_1^{-1}$ has **1** as its only eigenvalue. Thus $\eta_2\eta_1^{-1} = I$, the identity mapping, and $\eta_1 = \eta_2$. It follows immediately that $\sigma_1 = \sigma_2$.

We conclude by remarking that there is a polar decomposition in real vector spaces. Any nonsingular linear mapping τ can be uniquely written as $\sigma\eta$ with nonsingular positive definite symmetric σ and orthogonal η. The proof follows from the above by simply substituting the words "symmetric" for "hermitian" and "orthogonal" for "unitary."

ON THE ARITHMETIC MEAN-GEOMETRIC MEAN INEQUALITY

FERGUS GAINES, California Institute of Technology

The purpose of this note is to derive the arithmetic mean-geometric mean inequality from the following well-known matrix theorem of I. Schur [1].

THEOREM. *Let $X=(x_{ij})$ be an $n\times n$ matrix of complex numbers with characteristic roots $\lambda_1, \lambda_2, \cdots, \lambda_n$. Then*

$$\sum_{i,j=1}^{n} |x_{ij}|^2 \geqq \sum_{i=1}^{n} |\lambda_i|^2$$

with equality if and only if X is normal.

Let

$$A = \begin{bmatrix} 0 & a_1 & 0 & \cdots & 0 \\ 0 & 0 & a_2 & \cdots & 0 \\ \cdot & \cdot & \cdot & \cdots & \cdot \\ 0 & 0 & 0 & \cdots & a_{n-1} \\ a_n & 0 & 0 & \cdots & 0 \end{bmatrix}$$

where $a_i \geqq 0$, $i=1, 2, \cdots, n$. The characteristic roots of A are the nth roots of the product $a_1a_2\cdots a_n$, this is easily seen by simply calculating the characteristic polynomial of A. We now apply Schur's theorem to A. Thus

$$\sum_{i=1}^{n} a_i^2 \geqq n(a_1a_2\cdots a_n)^{2/n}$$

with equality if and only if A is normal, i.e. $AA^*=A^*A$ where A^* is the conjugate transpose of A. This means we get equality if and only if

$$\operatorname{diag}(a_1^2, a_2^2, \cdots, a_n^2) = \operatorname{diag}(a_n^2, a_1^2, \cdots, a_{n-1}^2),$$

i.e. if and only if $a_1=a_2=\cdots=a_n$.

If we let $a_i=x_i^{1/2}$, $i=1, 2, \cdots, n$, we get

$$\left(\sum_{i=1}^{n} x_i\right) \Big/ n \geqq (x_1x_2\cdots x_n)^{1/n},$$

where $x_i \geqq 0$, $i=1, 2, \cdots, n$, with equality if and only if $x_1=x_2=\cdots=x_n$, which is the arithmetic mean-geometric mean inequality.

REMARK. Schur's theorem can be used to generate inequalities once we are given a matrix and all its characteristic roots. However, since most of the matrices whose characteristic roots are known are normal, the cases considered by the author have almost all resulted in trivial or well-known identities.

This work was supported by a grant from the National Science Foundation.

THE STRUCTURE OF FUNDAMENTAL MATRICES IN THE NEIGHBORHOOD OF A SINGULARITY OF THE FIRST KIND

D. B. HILL, University of Vermont

The purpose of this note is to provide a new proof the standard theorem on the behavior of solution matrices in the vicinity of a first order pole. The proof is believed to be more direct and more easily taught than those previously available.

THEOREM. *Given the linear system* $\dot{U} = (1/z)A(z)U$, *where* $A(z) = \sum_0^\infty A_n z^n$ *is analytic in* $|z| < r$. *Then every fundamental matrix is of the form* $S(z)z^P$ *where* $S(z)$ *is analytic at* $z = 0$ *and* P *is a constant matrix. Further, if the eigenvalues of* A_0 *do not differ by a positive integer,* P *may be chosen to be* A_0.

Proof. If two eigenvalues of A_0 differ by a positive integer, we may reduce the equation to one in which the eigenvalues of the constant term do not differ by a positive integer by repeated application of the following lemma whose easy proof may be found in [1].

LEMMA 1. *Let the distinct characteristic roots of* A_0 *(disregarding their multiplicity) be* $\rho_1, \cdots, \rho_k$. *There exists a matrix function* R *of* z, *nonsingular for* $z \neq 0$ *and linear (hence analytic) in* z, *such that the substitution* $U = RV$ *transforms the equation for* V *into the form* $V = (1/z)\hat{A}(z)V$, *where* $\hat{A}_0$ *has eigenvalues* $\rho_1 - 1$, $\rho_2, \cdots, \rho_k$.

Hence it suffices to prove the theorem when A_0 has eigenvalues $\lambda_1, \cdots, \lambda_k$ such that no two differ by a positive integer. Furthermore, we may clearly assume that A_0 is in Jordan canonical form.

We will first show that there is a formal power series $S(z)$ such that $S(z)z^{A_0}$ formally satisfies the equation. Let $U = Vz^{A_0}$. Then V satisfies:

$$V = \left[\frac{A_0}{z}V - V\frac{A_0}{z}\right] + [A_1 + A_2 z + A_3 z^2 + \cdots]V. \tag{1}$$

Assume $V = \sum_0^\infty S_i z^i$. Then formally $A_0S_0 - S_0A_0 = 0$. Choose $S_0 = I$ which satisfies the equation. Now assume that $S_0, S_1, \cdots, S_{k-1}$ have been determined uniquely. For S_k one has the equation:

$$(kI - A_0)S_k + S_kA_0 = A_1S_{k-1} + A_2S_{k-2} + \cdots + A_k. \tag{2}$$

At this point we will digress from the main line of the proof to introduce an idea which will be extremely useful in what follows. Suppose that A is an $n \times n$ matrix and consider the linear transformation defined on the space of $n \times n$ matrices by $\sigma: X \to AX$. Thinking of the space of $n \times n$ matrices as an n^2 dimen-

sional vector space, by a well-known theorem in linear algebra σ can be represented as an $n^2\times n^2$ matrix denoted by $\tilde{A}$. On the other hand, the map $T: X\to XA$ can also be represented by an $n^2\times n^2$ matrix denoted by $\tilde{A}'$. Using this notation, equation (2) becomes:

$$(k\tilde{I} - \tilde{A}_0 + \tilde{A}_0')S_k = A_1S_{k-1} + \cdots + A_k \quad \text{where } k\tilde{I} - \tilde{A}_0 + \tilde{A}_0' \text{ is an } n^2 \times n^2 \tag{3}$$

matrix and S_k and the right hand side are n^2 vectors. The following lemma is a trivial special case of a theorem due to Hausner [2].

LEMMA 2. *Let X and Y be $n\times n$ matrices having $\alpha_1, \cdots, \alpha_n$ and $\beta_1, \cdots, \beta_n$ for their respective eigenvalues. Then the eigenvalues of the $n^2\times n^2$ matrix $\tilde{X}+\tilde{Y}'$ are $\alpha_i+\beta_j$; $i, j=1, \cdots, n$.*

Applying this lemma to $(k\tilde{I}-\tilde{A}_0)+\tilde{A}_0'$ we find that the eigenvalues of this matrix are $k-\lambda_i+\lambda_j$ where the λ_i are the eigenvalues of A_0. ($kI-A_0$ has eigenvalues $k-\lambda_i$ since A_0 is in Jordan form). By assumption $k-\lambda_i+\lambda_j\neq 0$ for all integers k, hence $k\tilde{I}-\tilde{A}_0+\tilde{A}_0'$ is nonsingular and equation (3) has a unique solution S_k. Thus we have shown that it is possible to determine S_i, $i=0, 1, 2, \cdots$, so that $(\sum_{i=0}^{\infty} S_iz^i)z^{A_0}$ satisfies formally the equation $\dot{U}=(1/z)A(z)U$.

We must now show that $\sum_0^\infty S_iz^i$ actually converges in some neighborhood of $z=0$.

LEMMA 3. *If B_k denotes the solution of:*

$$(kI - A_0)B_k + B_kA_0 = C \tag{4}$$

there is a constant M independent of k such that $\|B_k\| \leqq M\|C\|$, where $\|\ \|$ denotes any convenient matrix norm.

Proof of Lemma 3. $B_k=(k\tilde{I}-\tilde{A}_0+\tilde{A}_0')^{-1}C$. Now

$$\det(k\tilde{I} - \tilde{A}_0 + \tilde{A}_0') = \prod_{i,j=1}^{n} (k - \lambda_i + \lambda_j).$$

Each term in $(k\tilde{I}-\tilde{A}_0+\tilde{A}_0')^{-1}$ is the cofactor of an element of $(k\tilde{I}-\tilde{A}_0+\tilde{A}_0')^T$ divided by $\det(k\tilde{I}-\tilde{A}_0+\tilde{A}_0')$. Each cofactor contains a sum of products of at most n^2-1 terms $(k-\lambda_i+\lambda_j)$; hence each term in $(k\tilde{I}-\tilde{A}_0+\tilde{A}_0')^{-1}$ is a sum of terms of the form $\Gamma/\Pi(k-\lambda_i+\lambda_j)$, where Γ is independent of k. But the expression $|k-\lambda_i+\lambda_j|$ has a minimum m, over all i, j and k as is easily seen. Hence each term of the form $\Gamma/\Pi(k-\lambda_i+\lambda_j)$ is maximized (in absolute value) by Γ/m^P where P *is* the number of factors in the product. Hence there is a matrix D independent of k which maximizes $(k\tilde{I}-\tilde{A}_0+\tilde{A}_0')^{-1}$ in norm. Then clearly $\|B_k\| \leqq \|D\|\|C\|$.

Now choose a constant N such that $\|A_i\| \leqq N^i$. (It is clearly possible to do this since $\sum A_iz^i$ converges in $|z|<r$.)

We are now in a position to prove the convergence of $\sum S_i z^i$. We will show that $\|S_i\| \leqq N^i M(M+1)^{i-1}$. For $i=1$, $(1-\tilde{A}_0+\tilde{A}_0')S_1=A_1$ so by Lemma 3, $\|S_1\| \leqq M\|A_1\| \leqq MN$. Now suppose that the statement holds for $i=1, \cdots, n-1$. Then since:

$$
\begin{aligned}
(k\tilde{I} - \tilde{A}_0 + \tilde{A}_0')S_n &= A_1S_{n-1} + \cdots + A_n \\
\|S_n\| &\leqq M\|A_1S_{n-1} + \cdots + A_n\| \\
&\leqq M\{NM(M+1)^{n-2}N^{n-1} + \cdots + N^n\} \\
&= MN^n\{M(M+1)^{n-2} + \cdots + 1\} \\
&= MN^n\{1 + M + M(M+1) + \cdots + M(M+1)^{n-2}\} \\
&= MN^n(1+M) + M^2N^n\left\{\frac{(M+1) - (M+1)^{n-1}}{1-(M+1)}\right\} \\
&= N^nM(M+1)^{n-1}
\end{aligned}
$$

as asserted. Then trivially $\sum S_nZ^n$ converges if $|z|<1/(N(M+1))$. Furthermore $\sum S_nz^n$ is nonsingular at $z=0$ and hence by continuity is nonsingular in some neighborhood of $z=0$.

REMARKS. Since the proof of the theorem clearly hangs on Lemmas 2 and 3, it is probably a good idea in presenting the proof to students to take a matrix A_0 in Jordan form and exhibit the matrices $\tilde{A}_0'$ and $\tilde{A}_0$ and $k\tilde{I}-\tilde{A}_0+\tilde{A}_0'$, since this makes the two lemmas completely obvious.

BANACH LIMITS

LOUIS SUCHESTON, Ohio State University

The purpose of this note is didactic; we show how Banach limits, together with the identification of their extremal values [5] and a theorem of Lorentz [4] giving conditions for their uniqueness, may be simply introduced to an audience armed only with an old-fashioned version of the Hahn-Banach theorem. An elementary proof of Lorentz's theorem may be found in the book by Goffman and Pedrick [2], the chief difference of our approach being in the use of a simpler expression for the functional p.

DEFINITION. *Banach limits (or Banach-Mazur limits, or generalized limits) are linear functionals L on the space B of bounded sequences of real numbers $(x_n)_{n=0}^{\infty}$, satisfying the conditions:*

$$\text{(i)} \quad L(x_n) \geqq 0 \quad \textit{if} \quad x_n \geqq 0, \qquad n = 0, 1, \cdots,$$

(ii) $L(x_{n+1}) = L(x_n)$,

(iii) $L(1) = 1$.

A word about notation: $L(x_n)$ is of course L at $(x_n) = (x_0, x_1, \cdots)$. $L(x_{n+1})$ is L at $(x_1, x_2, \cdots)$. $L(1)$ is L at $(1, 1, \cdots)$.

THEOREM. (α) *Banach limits exist.* (β) *The maximal value of Banach limits on a sequence* (x_n) *is*

$$M(x_n) \overset{\text{def}}{=} \lim_{n\to\infty} \left(\sup_j \; n^{-1} \sum_{i=0}^{n-1} x_{i+j} \right). \tag{1}$$

(γ) *The minimal value of Banach limits on a sequence* (x_n) *is*

$$\lim_{n\to\infty} \left(\inf_j \; n^{-1} \sum_{i=0}^{n-1} x_{i+j} \right) \tag{2}$$

(δ) *A necessary and sufficient condition in order that all Banach limits on a sequence* (x_n) *agree and equal* s *is that*

$$\lim_{n\to\infty} \; n^{-1} \sum_{i=0}^{n-1} x_{i+j} = s$$

uniformly in j. *Hence on convergent sequences Banach limits agree with limits.*

Proof. First we prove that the limit as $n\to\infty$ in the expression (1) for M exists. (Another proof of this is in [5] incorporated in the proof that M equals the expression used for p in the original argument of Banach, [1], p. 34.) Set

$$c_n = \sup_j \; \frac{1}{n} \sum_{i=0}^{n-1} x_{i+j}.$$

We are to show that $\lim c_n$ exists. While (c_n) is not monotone, for each k, m one has $c_{km} \leqq c_m$. Thus

$$(r + km)c_{r+km} \leqq rc_r + kmc_{km} \leqq rc_r + kmc_m.$$

Dividing by $r+km$ and letting $k\to\infty$ with r, m fixed, we obtain

$$\limsup_{k\to\infty} c_{r+km} \leqq c_m.$$

Since this holds for $r = 1, 2, \cdots, m$, $\limsup c_n \leqq c_m$ for each m, and hence $\limsup c_n \leqq \liminf c_m$ which implies that $\lim c_n$ exists.

THE HAHN-BANACH THEOREM ([1], p. 27). *Let* B *be a linear space and* C *a subspace of* B. *Let* p *be a sublinear functional on* B: $p(x+y) \leqq p(x)+p(y)$ *and if* $a \geqq 0$, $p(ax) = ap(x)$. *Then if* f *is a linear functional on* C *with*

$$f(x) \leqq p(x) \tag{3}$$

for $x \in C$, f *can be extended to* B *so that* (3) *holds for* $x \in B$. *If* $y \in B - C$, *then the*

process of extension may begin by ascribing to $f(y)$ any value in the closed interval with left endpoint

$$\sup_{x\in C}\,[-p(-x-y)-f(x)] \tag{4}$$

and right endpoint

$$\inf_{x\in C}\,[p(x+y)-f(x)]. \tag{5}$$

We let B be the space of bounded sequences $x=(x_n)$ and we let C be the subspace of convergent sequences. The Hahn-Banach theorem is now applied with $p=M$ and $f=\lim$ on C. It is easy to see that if $\lim x_n=s$ then the Cesàro means of x_n converge to s, i.e. $\lim_{n\to\infty} n^{-1}(x_0+\cdots+x_{n-1})=s$ and also $M(x_n)=s$.

Proof of (α). We show that linear functionals $f=L$ obtained on B by the extension procedure satisfy (i), (ii) and (iii). For (iii) this is obvious, since each L coincides with lim on C. (i) follows from

$$L(x_n) = -L(-x_n) \geqq -p(-x_n) = -M(-x_n) \geqq 0$$

if $x_n\geqq 0$ for all n.

Finally, (ii) follows from the "telescoping" property of M

$$|M(x_{n+1}-x_n)| = \left|\lim_n[\sup_j n^{-1}(x_{j+n}-x_j)]\right| \leqq \lim_n 2n^{-1}\sup_j|x_j| = 0,$$

$$|M(x_n-x_{n+1})| = 0,$$

and the relations $L(x_{n+1}-x_n)\leqq M(x_{n+1}-x_n)=0$ and

$$L(x_{n+1}-x_n) = -L(x_n-x_{n+1}) \geqq -M(x_n-x_{n+1}) = 0.$$

REMARK. If instead of M, lim sup x_n were used as p, then the generalized limits thus obtained would not satisfy (ii) because lim sup does not have the "telescoping" property. However, lim sup of Cesàro averages could be used for p, this construction yielding some, but not all, Banach limits.

Proof of (β). We first show that given a sequence (y_n), there is a Banach limit L_0 such that $M(y_n)=L_0(y_n)$. We may assume $(y_n)\in B-C$. We construct L_0 by beginning the extension procedure with (y_n), defining $L_0(y_n)$ by (5):

$$L_0(y_n) = \inf_{(x_n)\in C}\,[M(x_n+y_n)-\lim x_n]$$

which equals $M(y_n)$, because the convergence of (x_n) implies $M(x_n+y_n)=\lim x_n+M(y_n)$. We now show that conversely, for each sequence (y_n) and each Banach limit L, $L(y_n)\leqq M(y_n)$. Note that $\sup_j z_j-z_n\geqq 0$, $n=0,1,\cdots$ implies by (i) and (iii) that always $\sup_j z_j\geqq L(z_n)$. If for a fixed m we let

$$z_n = m^{-1}\sum_{i=0}^{m-1} y_{i+n},$$

we have $L(y_n)=L(z_n)\leqq\sup_j z_j$. On letting $m\to\infty$, we obtain $L(y_n)\leqq M(y_n)$, which completes the proof of (β).

Proof of (γ). Apply (β) to the sequence $(-x_n)$.

Proof of (δ). (δ) is an immediate corollary of (β) together with (γ).

Banach limits, their maximal values, and sequences (called "almost convergent") on which all Banach limits agree have found applications in Ergodic Theory (cf. [5] where also further references are given). In the opposite direction, an interesting application of Ergodic Theory to Banach limits is due to Jerison [3].

In conclusion, we wish to acknowledge our debt to the paper [4] of Lorentz, and to a conversation with Professor Alfred Rényi. The author's work is in part supported by NSF Grant GP-1458.

A FURTHER EXTENSION OF OLIVIER'S THEOREM

HYMAN GABAI, University of Illinois, UICSM

1. The extension. In [1], Štěpánek derived an extension of Olivier's theorem [2]. In this paper we shall use Štěpánek's method of proof to derive the following extension of Štěpánek's theorem.

THEOREM. *Let* $\sum_{n=1}^{\infty} a_n$ *be a convergent series of real numbers,* $\sum_{n=1}^{\infty} 1/\alpha_n$ *a divergent series of positive numbers, and* (β_n) *a sequence such that* $(\alpha_{n+1}-\alpha_n+\beta_n)$ *is a bounded monotone sequence and one of the following conditions holds*:

(a) $\alpha_n a_n \geqq (\alpha_n+\beta_{n-1})a_{n-1}[n\geqq 2]$ or (b) $\alpha_n a_n \leqq (\alpha_n+\beta_{n-1})a_{n-1}[n\geqq 2]$.

Then $\lim \alpha_n a_n = 0$.

Proof. If the inequality (a) or the inequality (b) is multiplied by -1 it is immediately evident that we need only prove the theorem for the case (a) or for the case (b). We shall prove the theorem under the hypothesis that (a) holds.

Following Štěpánek, we define $r_1=s_1=0$, and for each integer $n\geqq 2$ we define:

$$r_n = \alpha_n a_n \text{ and } s_n = -\sum_{i=1}^{n-1}(\alpha_{i+1}-\alpha_i+\beta_i)a_i.$$

For each $n\geqq 1$ we define $h_n=r_n+s_n$.

Since $\sum_{n=1}^{\infty} a_n$ converges and $(\alpha_{n+1}-\alpha_n+\beta_n)$ is bounded and monotone,

it follows by Abel's test (see, for example, [3], page 314) that the series $\sum_{n=1}^{\infty}(\alpha_{n+1}-\alpha_n+\beta_n)a_n$ converges. Thus (s_n) is a convergent sequence.

Now, still following Štěpánek's methods, we note that the condition (a) may be written in the following form: $\alpha_n a_n \geqq \alpha_{n-1}a_{n-1}+(\alpha_n-\alpha_{n-1}+\beta_{n-1})a_{n-1}$. Therefore,

$$h_n = r_n + s_n = \alpha_n a_n - \sum_{i=1}^{n-1}(\alpha_{i+1}-\alpha_i+\beta_i)a_i$$

$$\geqq \alpha_{n-1}a_{n-1} - \sum_{i=1}^{n-2}(\alpha_{i+1}-\alpha_i+\beta_i)a_i = h_{n-1}.$$

Thus, (h_n) is monotone non-decreasing. Since $r_n = h_n - s_n$, with (h_n) an increasing sequence and (s_n) a convergent sequence, it follows that either (r_n) diverges to infinity or (r_n) converges.

If (r_n) diverges to infinity, then for some integer N,

$$n > N \Rightarrow a_n > 1/\alpha_n$$

and, since $\sum_{n=1}^{\infty} 1/\alpha_n$ is a divergent series of positive terms, it follows that $\sum_{n=1}^{\infty} a_n$ is a divergent series, contrary to our hypothesis. A similar argument shows that if (r_n) converges but does not converge to 0 then $\sum_{n=1}^{\infty} a_n$ diverges. Hence (r_n) converges to 0, and the proof is complete.

2. Applications. Štěpánek's theorem is obtained from the above theorem by replacing α_n by n, and β_n by a constant β. Other applications may be obtained by setting $\alpha_n = n^p [0<p<1]$, or by setting $\alpha_n = \log_k n$ (where k is any positive integer, and $\log_k n$ is the kth iterated logarithm of n). (See Corollary (1) and (2), below.)

Another application may be obtained by setting: $\alpha_n = n \log n \log_2 n \cdots \log_k n$ and

$$\beta_n = -\log(n+1)\log_2(n+1)\cdots\log_k(n+1) - \log_2(n+1)\cdots\log_k(n+1) - \cdots - \log_k(n+1).$$

For every positive integer k, the series $\sum_{n=1}^{\infty} 1/\alpha_n$ diverges. An inductive argument shows that for every positive integer k the sequence $(\alpha_{n+1}-\alpha_n+\beta_n)$ is monotone increasing and converges to 1. (See Corollary (3), below.)

Some of these applications are listed in the following

COROLLARY. *If* $\sum_{n=1}^{\infty} a_n$ *is a convergent series such that, for all sufficiently large* n:

(1) $a_n \leqq (1+n^{-p})a_{n-1}$ $[0 \leqq p \leqq 1]$, *then* $\lim n^p a_n = 0$;

(2) $a_n \leqq (1+(\log_k n)^{-1})a_{n-1}$, *then* $\lim (\log_k n)a_n = 0$;

(3) $a_n \leqq (1-n^{-1}-(n \log n)^{-1}-\cdots-(n \log n \cdots \log_{k-1} n)^{-1})a_{n-1}$, *then* $\lim(n \log n \log_2 n \cdots \log_k n)a_n = 0$.

(The inequalities (1), (2), and (3) may be reversed, and the same conclusions hold.)

3. Remarks. In the hypothesis of our theorem, we may replace the condition:

$$(\alpha_{n+1} - \alpha_n + \beta_n) \textit{ is a bounded monotone sequence,}$$

by the condition:

$$\sum_{n=1}^{\infty} | \alpha_{n+2} - 2\alpha_{n+1} + \alpha_n + \beta_{n+1} - \beta_n | \textit{ is a convergent series.}$$

The proof would require the application of the Dedekind test (see [3], page 315) in place of the Abel test.

We may also vary the hypothesis of the theorem by placing appropriate restrictions on the sequences $(\alpha_{n+1}-\alpha_n)$ and (β_n) individually. Thus, for example, we may state the theorem with the conditions that $(\alpha_{n+1}-\alpha_n)$ is a bounded monotone sequence and $\sum_{n=1}^{\infty} |\beta_{n+1}-\beta_n|$ is a convergent series.

The author wishes to thank Professor Herbert E. Vaughan for a number of helpful suggestions.

MOTIVATION OF TRUTH TABLES FROM TAUTOLOGIES

P. S. MARCUS, Shimer College and Illinois Institute of Technology

In symbolic logic, a teaching problem is presented by the conventions defining the truth table of the implication formed from two propositions p, q by the binary operator denoted by "$\Rightarrow$." One possible way to motivate these conventions is to derive them from simple tautologies which the student readily accepts on an intuitive basis. Three tautologies which can be used for this purpose are:

1. $p \Rightarrow p$ or any proposition implies itself.
2. $(p \wedge q) \Rightarrow p$ or any proposition in conjunction with another proposition still implies itself.
3. $\sim(p \wedge \sim p)$ or any contradiction is false.

From these tautologies one may derive the truth table for $p \Rightarrow q$ as follows:

If we grant that $p \Rightarrow p$ is a tautology, then in particular a false proposition implies itself. This gives us one particular example of a true implication with false hypothesis and false conclusion. But since computation of truth values depends only on truth values of components, this one special case is enough to establish the convention that an implication with false hypothesis and false conclusion is always counted as true. From the same tautology and by the same reasoning it follows that an implication with true hypothesis and true conclusion is also counted as true.

Our next step is to use the tautology $(p \wedge q) \Rightarrow p$. If we grant that $(p \wedge q) \Rightarrow p$ is a tautology, then it holds true for any two propositions p, q. In particular, it holds for the two propositions p and $\sim p$. It follows that $(p \wedge \sim p) \Rightarrow p$ is always true. But by the last of our three tautologies, the hypothesis here is always false. Hence, if p is true, we have a true implication with the false hypothesis $p \wedge \sim p$ and the true conclusion p. Again, this particular example is sufficient to establish the convention of counting as true any implication with false hypothesis and true conclusion.

So, in three of the four possible cases of the truth table, an implication is counted as true. Unless an implication is to be regarded as a tautology, the remaining case is false, and this of course is the case where the hypothesis is true and the conclusion is false. This completes the determination of the truth table of an implication $p \Rightarrow q$.

ON THE CONTINUITY OF MONOTONIC FUNCTIONS

A. F. BEARDON, University of Maryland

The following result appears in many well-known texts (e.g. [1] p. 78).

THEOREM 1. *Let f be a real-valued, continuous, strictly increasing function on $[a, b]$. Then f^{-1} is also a continuous, strictly increasing function.*

The topological importance of this result seems to overshadow the following elementary, but more general, result.

THEOREM 2. *Let f be a real valued, strictly increasing function defined on a set D of real numbers. Then f^{-1} is a continuous, strictly increasing function if D is an open, closed, or connected set.*

Proof. Clearly f^{-1} is strictly increasing. Moreover it is easily proved that if x_0 is an interior point of D then f^{-1} is continuous at $f(x_0)$ and thus the result is true if D is open.

If D is connected then it must necessarily be an interval and if c is an endpoint of D which belongs to D it is evident that f^{-1} is continuous at $f(c)$.

Finally, suppose that D is closed. We can extend f to a function f^* whose domain includes all open intervals (a, b) where $a, b \in D$ and $(a, b) \cap D = \varnothing$ by the equation

$$f^*(x) = f(a) + \frac{f(b) - f(a)}{b - a}(x - a) \qquad x \in (a, b),$$

and the extended function f^* is strictly increasing on its domain of definition D^*. The assumption that D^* is disconnected leads immediately to a contradiction and hence $(f^*)^{-1}$ is continuous on $f^*(D^*)$. Thus the restriction of $(f^*)^{-1}$ to $f(D)$, namely f^{-1}, is continuous on $f(D)$ and the proof is complete.

The following result is a restatement of Theorem 2.

THEOREM 3. *Let f be a real-valued, strictly increasing function defined on a set D of real numbers. Then f is continuous on D if $f(D)$ is an open, closed, or connected set.*

Finally, we have the following result.

THEOREM 4. *Let f be a real-valued, strictly increasing function defined on a set D of real numbers which is open, closed or connected. Then f maps relatively open subsets of D onto relatively open subsets of $f(D)$.*

Proof. From Theorem 2 we can deduce that f^{-1} is continuous on $f(D)$. Equivalently, ([1] p. 80), $(f^{-1})^{-1}=f$ maps relatively open subsets of D onto relatively open subsets of $f(D)$ and this is the required result.

ANOTHER PROOF OF ASCOLI'S THEOREM

ADAM KLEPPNER, University of Maryland

One of the forms of Ascoli's Theorem asserts that a subset A of $C(X)$, where X is a locally compact Hausdorff space, is relatively compact for the topology of uniform convergence on compact sets if and only if A is equicontinuous and, for each $x\in X$, the set $A(x)=\{f(x): f\in A\}$ is bounded. Although the necessity of these conditions is easily established, most proofs of their sufficiency rely on a diagonal argument of Tychonoff's Theorem, or perhaps something more complicated. We shall give here a short proof which avoids these procedures and depends instead on the following fact.

LEMMA. *Let A be a family of bounded functions on the topological space X, suppose that X is a finite union of subsets, $X=\bigcup_1^n N_i$, and for each i let $A_i=A\,|\,N_i=\{f\,|\,N_i: f\in A\}$. Provide A and each A_i with the sup norm. If for some $\epsilon>0$ each A_i contains a finite $(\epsilon/2)$-dense set, then A contains a finite ϵ-dense set.*

To prove this, we provide $\prod_1^n A_i$ with the metric $d((f_i),(g_i))=\max_i \|f_i-g_i\|_i$, where $\|\ \|_i$ is the sup norm on N_i. If D_i is a finite $(\epsilon/2)$-dense set in A_i, then $\prod_1^n D_i$ is a finite $(\epsilon/2)$-dense set in $\prod_1^n A_i$. Thus every subset of $\prod_1^n A_i$ contains a finite set which is at least ϵ-dense. The natural embedding of A into $\prod_1^n A_i$, $f\to(f\,|\,N_1,\cdots,f\,|\,N_n)$, is an isometry so that A contains a finite ϵ-dense set.

To prove the theorem it must be shown that for each compact $K\subset X$ and each $\epsilon>0$, A contains a finite set which is ϵ-dense for the pseudometric of uniform convergence on K. Thus we may restrict everything to K and assume that X is compact. Because A is equicontinuous there exists for each $\epsilon>0$ and each $x\in X$ a compact neighborhood N_x of x such that $|f(y)-f(x)|<\epsilon/6$ for all $y\in N_x$ and $f\in A$. A finite number of these neighborhoods, $N_i=N_{x_i}$, $1\leqq i\leqq n$, cover X. Each

of the sets $A(x_i)$ is bounded; hence there exists for each i a finite number of functions $f_{ij} \in A$ such that the set $\{f_{ij}(x_i)\}$ is $\epsilon/6$-dense in $A(x_i)$. For each i and each $f \in A$ there exists f_{ij} such that $|f(x_i) - f_{ij}(x_i)| < \epsilon/6$. For all $y \in N_i$ we have

$$|f(y) - f_{ij}(y)| \leqq |f(y) - f(x_i)| + |f(x_i) - f_{ij}(x_i)| + |f_{ij}(x_i) - f_{ij}(y)| < \epsilon/2.$$

Thus $A_i = A \mid N_i$ contains a finite set which is $(\epsilon/2)$-dense for the sup norm on A_i, and by the lemma A contains a finite ϵ-dense set.

SUMMER INSTITUTES FOR COLLEGE TEACHERS

LEONARD GILLMAN, Chairman, CUPM Panel on College Teacher Preparation
DON THOMSEN, Chairman, MAA Committee on Institutes

Among various types of programs for continuing the education of college mathematics teachers, one which has natural logistic advantages is the summer institute. Through its Committee on Institutes, the MAA has been directly involved in conducting several institutes for experienced college professors. Moreover, a study of existing summer programs for college teachers has been an item of high priority on the agenda of CUPM's newly formed Panel on College Teacher Preparation. This Panel has conferred with a number of persons who have directed two or more such programs, and is now planning further study which may lead to some specific recommendations for summer institute courses.

Institutes held in recent years have pursued various objectives:

1. One kind of institute is directed at training teachers of precollege teachers and is particularly concerned with curricular reforms and experiments in the teaching of precollege mathematics.

2. Another provides fundamental instruction for college teachers not prepared for their current or forthcoming teaching assignments. At this kind of institute the subject matter is often undergraduate mathematics presented from a higher standpoint.

3. For teachers who have adequate general background but need special study to introduce a new course, there have been institutes devoted to specific topics in mathematics such as linear algebra, topology, probability and statistics, or applied mathematics.

4. There have been several institutes devoted to recent research with the objective of stimulating active interest in research and encouraging the development of seminars and other scholarly activities at the home institutions of the participants.

Other types of institutes would also serve important purposes. For instance, college teachers could be brought together to collaborate in the preparation of instructional materials, or in the reorganization of courses and curricula to take into account recent trends in mathematics education.

The range of possible programs within each type of institute is wide, and any particular program may combine features of several types. The purposes above are all extremely worth while, and the Panel is convinced that a greatly expanded effort in the direction of summer institutes of all types is urgently needed. In the programs for which we have data, applications have outnumbered acceptances by more than six to one. Even if summer institutes are to reach only ten percent of all college mathematics teachers each summer, the number of institutes will need to be approximately tripled.

Accordingly, the CUPM Panel on College Teacher Preparation and the Association's Committee on Institutes strongly urge that many more institutions submit proposals for summer institutes for college teachers, that supporting agencies extend their support of such institutes to the level just described, and that directors of the institutes publicize their programs as widely as possible to eligible college teachers.

PROBLEMS AND SOLUTIONS

EDITED BY E. P. STARKE

COLLABORATING EDITORS: J. BARLAZ, Rutgers—The State University; L. CARLITZ, Duke University; HASKELL COHEN, Louisiana State University; H. EVES, University of Maine; M. S. KLAMKIN, Ford Scientific Laboratory; R. C. LYNDON, University of Michigan; and A. WILANSKY, Lehigh University.

All problems (both elementary and advanced) proposed for inclusion in this Department should be sent to E. P. Starke, 1000 Kensington Ave., Plainfield, N. J. 07060. Proposers of problems are urged to enclose any solutions or information that will assist the editors. Ordinarily, problems in well-known textbooks and results in generally accessible sources are not appropriate for this Department. No solutions (except those accompanying proposals) should be sent to Professor Starke.

ELEMENTARY PROBLEMS

Solutions of Elementary Problems should be sent to M. S. Klamkin, Ford Scientific Laboratory, P.O. Box 2053, Dearborn, Mich. 48121. To facilitate their consideration, solutions for Elementary Problems in this issue should be typed or written legibly on separate, signed sheets and should be mailed before July 31, 1967. ***Contributors (in the United States) who desire acknowledgement of receipt of their solutions are asked to enclose self-addressed stamped postcards.***

E 1965. *Proposed by Hyman Gabai and Steven Szabo, University of Illinois and UICSM*

Given any triangle ABC, let P and Q be the midpoints of sides AB and AC, respectively. Let G and G' be points on the perpendicular bisector of AB such

that $GG'=AC$, P is the midpoint of GG', and segment GP contains no points of the interior of triangle ABC. Let H and H' be points on the perpendicular bisector of AC such that $HH'=AB$, Q is the midpoint of HH', and segment QH contains no points of the interior of triangle ABC. Prove (a) $GH^2+G'H'^2=AB^2+AC^2$ and (b) $G'H^2+GH'^2=BC^2$.

E 1966. *Proposed by M. S. Klamkin, Ford Scientific Laboratory*

Show how to construct a regular tetrahedron if the vertices lie on four given parallel planes.

E 1967. *Proposed by W. L. Blanchard, University of Rochester*

Prove that for any positive integers a, b the set of all $ma+nb$ (m, n positive integers) includes all multiples of (a, b) larger than $[a, b]$. Show also that this is the best possible statement. Note: (a, b) is the greatest common divisor and $[a, b]$ is the least common multiple.

E 1968. *Proposed by Erwin Just, Bronx Community College, N. Y.*

Prove that, for any polynomial $p(x)$ and any integer k, there exist k consecutive values of x such that $p(x)$ is composite.

E 1969. *Proposed by J. M. Quoniam, Saint-Etienne, France*

The centers of the internal squares constructed on the sides BC, CA, AB of a triangle are collinear if $\cot\omega=2$, where ω is the Brocard angle of ABC.

E 1970. *Proposed by R. E. Dowds, State University College of New York, Fredonia*

Define $f(x)=\sin(1/x)$, $x\neq 0$, and $f(0)=0$. Is the function f a derivative? In other words, does there exist a function F such that $F'(x)=f(x)$ for all x, including $x=0$?

E 1971. *Proposed by R. A. Whiteman, Illinois Institute of Technology*

Let $g(x)=a_mx^m+a_{m-1}x^{m-1}+\cdots+a_1x+a_0$, where the coefficients are real numbers and $a_m>0$. Define a polynomial $G(x)$ by $G(x)=[g(x)]^2-g'(x)$. Prove that, if $g(x)$ has m distinct real roots, then

(a) for m equal to an odd positive integer, the polynomial $G(x)$ has $m+1$ real roots and $m-1$ complex roots, and

(b) for m equal to an even positive integer, $G(x)$ has m real roots and m complex roots.

E 1972. *Proposed by E. P. Starke, Plainfield, N. J.*

There are n consecutive positive integers whose squares can be separated into two sets having the same sum, if and only if there exist two positive integers r, s, $r>s$, such that $n=r^2-s^2$.

E 1973. *Proposed by H. P. Bieri, Spiez, Switzerland*

Consider triangle ABC and its circumcircle. Let A_1, A_2; B_1, B_2; C_1, C_2 be the trisection points of arcs BC, CA, AB of the circumcircle, arranged so that B, A_1, A_2, C, B_1, B_2, A, C_1, C_2, B appear in this cyclic order on the circumference. Prove that A_1B_2, B_1C_2, C_1A_2 determine the side lines of a triangle homothetic to the Morley triangle of ABC.

E 1974. *Proposed by Richard Harter, Brookline, Mass.*

Let the n variables $x_1, \cdots, x_n$ satisfy a relationship $f(x_1, \cdots, x_n)=0$. Define the nth order determinant A as follows: $A_{ii}=1$, $A_{ij}=\partial x_i/\partial x_j$, $i\neq j$. Prove $A=-(n-2)2^{n-1}$.

SOLUTIONS OF ELEMENTARY PROBLEMS

Notice by the Editors. The lost correspondence regarding Solutions of Elementary Problems E 1835 through E 1894 has at last been located and will be processed as rapidly as possible. The editors are very grateful to contributors who responded to our SOS in the February issue (p. 199) and supplied duplicates of their earlier solutions. However, no further duplicates are now needed.

Integral Triangles with Given Perimeter

E 1825 [1965, 1020]. *Proposed by A. K. Austin, The University, Sheffield, England*

Find the number of noncongruent triangles with integral sides and perimeter n.

Solution by Sidney Spital and Yu Chang, California State Polytechnic College, Pomona. We shorten the notation for two useful quantities: $h=[(n+2)/3]$ and $k=[(n+1)/2]$, where the brackets denote the greatest integer function. From the perimeter length n we attempt to select (nondegenerate) triangles of side lengths a, b, c. Two conditions are needed to assure noncongruence and satisfaction of the triangle inequality: (1) ordering the sides, $c\geqq b\geqq a$ and (2) limiting the largest side c to $n/3\leqq c<n/2$. We begin the enumeration of all such triangles with integral sides by choosing c from $\{h, h+1, \cdots, k-1\}$. Since any selection leaves $(n-c)$ of perimeter remaining, the intermediate side b may be chosen in N_c ways from

$$\{[(n-c+1)/2], [(n-c+1)/2]+1, \cdots, c\}.$$

Hence $N_c=c-[(n-c+1)/2]+1$ which easily converts to

$$N_c=\tfrac{1}{4}(6c-2n+3)+\tfrac{1}{4}(-1)^{n-c}.$$

The desired number of triangles is therefore given by

$$\sum_{c=h}^{k-1} N_c = \sum_{c=h}^{k-1} \tfrac{1}{4}\,(6c - 2n + 3) + \sum_{c=h}^{k-1} \tfrac{1}{4}(-1)^{n-c}.$$

The first sum is the sum of an arithmetic progression and equals $\frac{1}{4}(k-h) \cdot (3k+3h-2n)$. The second sum adds terms which alternate between $\pm\frac{1}{4}$; thus in no case does its absolute value exceed $\frac{1}{4}$. Hence

$$f(n) = \left\{\tfrac{1}{4}(k - h)(3k + 3h - 2n)\right\},$$

where $\{\ \}$ denotes the nearest integer and $f(n)$ is the required number of triangles.

Also solved by Irving Adler, Walter Bluger, J. M. Brooke, L. Carlitz, H. K. Crowder, Jorge Dou (Spain), R. B. Eggleton (Australia), J. M. Elkin, A. R. Erskine, N. J. Fine, D. M. Hancasky, D. C. B. Marsh, Liselotte Miller, Peter Nyikos, Brian O'Haire, D. A. Penner, Walter Penney, L. A. Ringenberg, Simon Vatriquant (Belgium), and the proposer. Several solvers gave the correct result but without any indication of the method of deduction.

Vatriquant obtained the result by using the recurrence relations $f(2m+4)=f(2m+1)$, $f(2m)=f(2m-12)+m-3$. Fine used $f(2n)=f(n)+f(n-1)+f(n-2)+f(n-3)$ together with $f(2m+4)=f(2m+1)$. Miller found the problem and complete solution as no. 30 in Yaglom and Yaglom, *Challenging Mathematical Problems with Elementary Solutions*.

The final result is given in many forms. Dou writes

$$f(n) = \left[\frac{n^2 + 3n + 21 - (-1)^n 3n}{48}\right].$$

Eggleton puts $n=12p+2q$, for $0 \leqq q < 6$ and $p \geqq 0$. Then

$$f(12p + 2q) = 3p^2 + pq + \left[\frac{q^2 - q + 5}{10}\right];$$

$f(n)$ for odd n is obtained from $f(2m+1)=f(2m+4)$. Bluger defines p and q so that $\frac{1}{2}n=6p+q$ if n is even, $\frac{1}{2}(n+3)=6p+q$ if n is odd, where q is so chosen that $|q| \leqq 3$. Then for $q=\pm 3$, $f(n) = 3p^2+pq+1$; in all other cases, $f(n)=3p^2+pq$.

Quadrilateral with Rational Sides and Diagonals

E 1826 [1965, 1020]. *Proposed by A. K. Austin, The University, Sheffield, England*

Does there exist a quadrilateral $ABCD$ such that the sides and diagonals have rational length, but AO, BO, CO, DO are all irrational? O is the intersection of the diagonals.

I. *Solution by D. A. Penner, University of Maryland.* Set up the quadrilateral with vertices (0, 0), $(r, 0)$, (x_1, y_1), (x_2, y_2) respectively. Since all sides and diagonals have rational length, the squares of the lengths are rational, and it is easy to show that x_1, x_2, r, y_1y_2 and y_1^2 are all rational, as well as $\sqrt{(x_1^2+y_1^2)}$. The intersection of the diagonals is found to be

$$\left(\frac{rx_1y_2}{ry_1 + x_1y_2 - x_2y_1}, \frac{ry_1y_2}{ry_1 + x_1y_2 - x_2y_1}\right).$$

The distance of this intersection from the vertex (0, 0) is

$$\frac{ry_2}{ry_1 + x_1y_2 - x_2y_1}\sqrt{(x_1^2 + y_1^2)} = \frac{(y_1y_2)r}{y_1^2r + (y_1y_2)x_1 - y_1^2x_2}\sqrt{(x_1^2 + y_1^2)}.$$

But every term is rational, so AO is rational. Thus a quadrilateral of the requested type is impossible.

II. *Solution by D. C. B. Marsh, Colorado School of Mines.* No. If the sides and diagonals of $ABCD$ are rational, then from the Law of Cosines, the cosine of the angle formed by any pair of these lines is rational; hence the sines of the angles have rational squares. From the Law of Sines, OA, OB, OC, OD have rational squares, also $OA+OC$ and $OB+OD$ are rational. For positive values this implies that the segments of the diagonals must also be rational.

Also solved by R. B. Eggleton (Australia), and Michael Goldberg.

Goldberg refers to Dickson, *History of the Theory of Numbers*, vol. 2, p. 217, where there is given the proof due to E. E. Kummer (J. Reine Angew. Math., 37 (1948) 1–20.)

Simultaneous Linear Equations

E 1827 [1965, 1020]. *Proposed by Joseph Arkin, Suffern, N. Y.*

Given an integer $n \geqq 2$ and the system of $n-1$ equations:

$$0 = a_nx_n + \binom{n}{1}x_{n-1} + \binom{n}{2}x_{n-2} + \binom{n}{3}x_{n-3} + \cdots + \binom{n}{n-2}x_2 + 1,$$

$$0 = a_{n-1}x_n + \binom{n-1}{1}x_{n-1} + \binom{n-1}{2}x_{n-2} + \binom{n-1}{3}x_{n-3} + \cdots + \binom{n-1}{n-2}x_2 + 1,$$

$$0 = a_{n-2}x_n + \binom{n-2}{1}x_{n-1} + \binom{n-2}{2}x_{n-2} + \binom{n-2}{3}x_{n-3} + \cdots + 0 + 1,$$

$$\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots\cdots$$

$$0 = a_3x_n + \binom{3}{1}x_{n-1} + \binom{3}{2}x_{n-2} + 0 + \cdots + 0 + 1,$$

$$0 = a_2x_n + \binom{2}{1}x_{n-1} + 0 + 0 + \cdots + 0 + 1,$$

in $n-1$ quantities $x_2, x_3, \cdots, x_n$. Determine the value of the one quantity x_n in terms of the a_j.

Solution by Uri J. Schild, Bar Ilan University, Ramat Gan, Israel. Introducing $m=n-k$ in the well-known formula $\sum_{i=0}^{m-1}\binom{n}{i}B_i=0$ and multiplying each term by $\binom{n}{k}$, we obtain

$$(*) \qquad \binom{n}{k} + \sum_{i=1}^{n-k-1} \binom{n-i}{k}\binom{n}{i} B_i = 0,$$

where the B_i are Bernoulli numbers. Consider the determinant

$$D(c_2, c_3, \cdots, c_n) = \begin{vmatrix} c_n & \binom{n}{1} & \binom{n}{2} & \cdots & \binom{n}{n-3} & \binom{n}{n-2} \\ c_{n-1} & \binom{n-1}{1} & \binom{n-1}{2} & \cdots & \binom{n-1}{n-3} & \binom{n-1}{n-2} \\ c_{n-2} & \binom{n-2}{1} & \binom{n-2}{2} & \cdots & \binom{n-2}{n-3} & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ c_3 & \binom{3}{1} & \binom{3}{2} & \cdots & 0 & 0 \\ c_2 & \binom{2}{1} & 0 & \cdots & 0 & 0 \end{vmatrix}.$$

Multiplying row i by $\binom{n}{i-1}B_{i-1}$ and adding to row one, for all $i=2, 3, \cdots, n-1$, we see by (*) that all elements in row one except the first become 0. The nonzero element in row one multiplied by its cofactor C_{11} yields the value of D. Here $C_{11} = (-1)^{n-1}(n-1)!$. By Cramer's rule we therefore obtain for x_n:

$$x_n = \frac{D(-1, -1, \cdots, -1)}{D(a_2, a_3, \cdots, a_n)} = \frac{-\sum_{i=0}^{n-2}\binom{n}{i}B_i}{\sum_{i=0}^{n-2} a_{n-i}\binom{n}{i}B_i} = \frac{nB_{n-1}}{\sum_{i=0}^{n-2} a_{n-i}\binom{n}{i}B_i}.$$

Also solved by Sidney Spital, and the proposer.

Differential Equation

E 1828 [1965, 1021]. *Proposed by D. S. Mitrinović, University of Belgrade, Yugoslavia*

Form the differential equation for which the general solution is

$$y = \sum_{k=1}^{n} A_k e^{a_k x},$$

where the constants A_k and a_k are arbitrary.

I. *Editorial Comment.* In the original statement, the problem was misprinted to read $\sum_{k=1}^{\infty} A_k e^{a_k x}$, for which no solution is possible with arbitrary a_k.

David Cohoon of Purdue University offered a solution of the problem in this form provided the a_k are assumed given—the solution being possible only if $|a_k| \to \infty$ as $k \to \infty$:

$$\left\{ \prod_{k=1}^{\infty} \left(1 - \frac{D_x}{a_k}\right) E_k(x, D_x) \right\} y(x) = 0,$$

where

$$E_k(x, D_x) = \exp\left(\frac{D_x}{a_k} + \frac{1}{2}\frac{D_x^2}{a_k^2} + \cdots + \frac{1}{k+1}\frac{D_x^{nk}}{a_k^{nk}}\right)$$

as in the Weierstrass factor theorem.

II. *Solution by J. Barlaz, Rutgers—The State University.* We must eliminate a_k, A_k from the expressions for $y, y', \cdots, y^{(2n)}$. We have

$$y^{(i)} = \sum_{k=1}^{n} a_k^i A_k e^{a_k x} \qquad i = 0, 1, \cdots, n.$$

From the $n+1$ equations we eliminate $A_k e^{a_k x}$, $k = 0, 1, \cdots, n$ and obtain

$$\begin{vmatrix} y & 1 & 1 & \cdots & 1 \\ y' & -a_1 & -a_2 & \cdots & -a_n \\ y'' & (-a_1)^2 & (-a_2)^2 & \cdots & (-a_n)^2 \\ \cdots & \cdots & \cdots & \cdots & \cdots \\ y^{(n)} & (-a_1)^n & (-a_2)^n & \cdots & (-a_n)^n \end{vmatrix} = 0.$$

This is linear of the nth order, of the form

$$(*) \qquad c_0 y + c_1 y' + c_2 y'' + \cdots + c_n y^{(n)} = 0,$$

where $c_0, \cdots, c_n$ are arbitrary constants with a single dependency relation. Differentiate (*) n times to eliminate the $n+1$ constants. The final result is

$$\begin{vmatrix} y & y' & \cdots & y^{(n)} \\ y' & y'' & \cdots & y^{(n+1)} \\ \cdots & \cdots & \cdots & \cdots \\ y^{(n)} & y^{(n+1)} & \cdots & y^{(2n)} \end{vmatrix} = 0.$$

Similar solution contributed by D. C. B. Marsh.

A Polynomial Identity

E 1829 [1965, 1021] *Proposed by M. J. Pascual and S. D. Beck, Watervliet Arsenal, N. Y.*

If m is a positive integer and x is arbitrary, establish the following identity:

$$\sum_{k=m}^{2m-1}\binom{2m-1}{k}x^k(1-x)^{2m-1-k}=\sum_{k=m}^{2m-1}\binom{k-1}{m-1}x^m(1-x)^{k-m}.$$

Solution by Leonard Carlitz, Duke University. With change of index after dividing through by $x^m(1-x)^{m-1}$, the stated equality can be written in the form

$$\sum_{k=0}^{m-1}\binom{2m-1}{k+m}\left(\frac{x}{1-x}\right)^k=\sum_{k=0}^{m-1}\binom{k+m-1}{m-1}(1-x)^{k-m+1}.$$

For $y=x/(1-x)$, $1+y=1/(1-x)$, this becomes

$$(*)\qquad \sum_{k=0}^{m-1}\binom{2m-1}{k+m}y^k=\sum_{k=0}^{m-1}\binom{k+m-1}{m-1}(1+y)^{m-k-1}.$$

The right member of (*) is equal to

$$\sum_{k=0}^{m-1}\binom{k+m-1}{m-1}\sum_{j=0}^{m-k-1}\binom{m-k-1}{j}y^j$$

$$=\sum_{j=0}^{m-1}y^j\sum_{k=0}^{m-j-1}\binom{k+m-1}{m-1}\binom{m-k-1}{j}.$$

Since it is known that

$$\sum_{k=0}^{n}\binom{a+k}{a}\binom{b+n-k}{b}=\binom{a+b+n+1}{n},$$

we have

$$\sum_{k=0}^{m-j-1}\binom{k+m-1}{m-1}\binom{m-k-1}{j}=\binom{2m-1}{m-j-1}=\binom{2m-1}{m+j}$$

from which (*) follows at once.

Also solved by J. D. Austin, L. J. Burton, M. A. Bershad, Carey M. Jensen, D. C. B. Marsh, Sidney Spital, K. L. Yocom, and the proposer.

The proposer gives a solution using probability theory. Yocom shows

$$f_{m+1}(x)-f_m(x)=x^m(1-x)^m\binom{2m-1}{m}(2x-1)=g_{m+1}(x)-g_m(x),$$

where $f_m(x)$, $g_m(x)$ are the left, right members of the given identity.

Semigroup Which Is Both Left and Right Regular

E 1830 [1965, 1021]. *Proposed by Michael Gemignani, University of Notre Dame*

Let $\{S,\cdot\}$ be a semigroup such that, given any $a\in S$, x and y can be found in S such that $(xa)a=a$, and $a(ay)=a$. Prove (1) Every element $a\in S$ has at least one two-sided identity, i.e. given a, $\exists e_a$ in S with $e_aa=ae_a=a$; and (2) each

$a \in S$ has at least one two-sided inverse, say b_a, such that $b_a a = a b_a = e_a$, e_a being a two-sided identity for a.

Solution by D. F. Dawson, North Texas State University. Let $a \in S$ and $xaa = a = aay$, S being associative. Let $e_a = xa = xaay = ay$. Then $e_a a = xaa = a = aay = ae_a$. Let $b_a = xxa = xay = ayy$. Then $b_a a = xxaa = xa = e_a = ay = aayy = ab_a$.

Also solved by G. A. Alberts, José Asseo, T. A. Atchison, D. A. Blaeuer, W. A. Bodden, Mary Beth Bridgham, J. L. Brown, Jr., P. L. Chabot, Jon Cole, A. J. D'Aristotle, M. J. DeLeon, R. B. Eggleton (Australia), E. W. Ewing, R. W. Feldman, Neal Felsinger, J. E. Homer, Jr., G. A. Johanson, Erwin Just, U. S. Kahlon (India), H. P. Konen, R. N. Leggett, Jr., C. W. Leininger, Edward Lester, Marijo LeVan, Steve Ligh, C. C. Lindner. J. L. Linnstaedter, L. B. Loyd, W. A. McWorter, D. C. B. Marsh, J. J. Martinez, Jose Mason & C. J. Maxson, Helen Merkel, G. L. Musser, D. E. Myers, D. E. Nixon, F. D. Parker, S. N. Rao & A. M. Vaidya (India), Henry Ricardo, M. D. Richek, Azriel Rosenfeld, M.S.R.K. Sastry, Carol Ann Schiller, P. S. Schnare, A. L. Selman & R. B. McNeil, Ronald Shubert, D. L. Silverman, Al Somayajulu, J. F. Standish, D. R. Stark, R. L. Taylor, Kenneth Tolo, P. R. Winter, and the proposer.

For other properties of such semigroups, Leininger refers to Clifford & Preston, *The Algebraic Theory of Semigroups*, vol. 1, pp. 121–123.

Polynomial over an Embedded Field

E 1831 [1965, 1021]. *Proposed by William Becker, New York University*

Let F and G be fields with G (properly) embedded in F. Let $P(x)$ be a polynomial with coefficients in G such that $x \in G$ implies $P(x) \in G$, and $x \in (F-G)$ implies $P(x) \in (F-G)$. Must $P(x)$ be linear? (Compare E 1642 [1964, 914] and E 1696 [1965, 550].)

I. *Solution by E. W. Ewing, Western Kentucky State College.* No. Let $G = \{0, 1\}$ be the field of integers modulo 2. Now x^2+x+1 is irreducible over G. Let $F = \{0, 1, \alpha, \alpha+1\}$ be the splitting field for x^2+x+1 where $\alpha^2+\alpha+1=0$ or $\alpha^2 = -\alpha-1 = \alpha+1$. Let $P(x) = x^2+1$. It is easy to see that $P(\alpha) = \alpha$ and $P(\alpha+1) = \alpha+1$, and so, $P(x)$ satisfies the conditions of the problem but $P(x)$ is not linear.

II. *Solution by J. T. Lloyd, Lehigh University.* If G denotes the field of algebraic numbers and F denotes the complexes, then any polynomial $P(x)$ over G has the property that $x \in G$ implies $P(x) \in G$ and $x \in (F-G)$ implies $P(x) \in (F-G)$.

Also solved by L. J. Burton, Erwin Just, Marijo LeVan, C. C. Lindner, D. C. B. Marsh, Azriel Rosenfeld, M. S. R. K. Sastry, S. Smith, Jr., Preston Stein, J. E. Wilkins, Jr., and K. L. Yocom.

A Ladder and Wall Problem

E 1832 [1965, 1021]. *Proposed by Alan Sutcliffe, Congleton, Cheshire, England*

There is a well-known problem in which a ladder rests against a wall and just touches a cube having one face in contact with the wall. The lengths of the ladder and an edge of the cube are given, and it is required to find the distance

of the ends of the ladder from the base of the wall. When are all four quantities integers?

Solution by M. S. Demos, Drexel Institute of Technology. Let z be the length of the ladder, e the edge of the cube, and x and y the distances of the ends of the ladder from the base of the wall. Then $x^2+y^2=z^2$ and (from similar triangles) $xy=e(x+y)$ are necessary and sufficient conditions for the given figure. For integral solutions, suppose $(x, y)=d$, $x=ad$, $y=bd$, $(a, b)=1$. Then $dab=e(a+b)$, and $(ab, a+b)=1$. Therefore $d=k(a+b)$ where k is any integer, and it follows that $e=kab$, $x=ak(a+b)$, $y=bk(a+b)$, $z=ck(a+b)$, where a, b, c are any primitive solution of $a^2+b^2=c^2$ $[a=u^2-v^2, b=2uv, c=u^2+v^2, u>v, (u, v)=1, 2\mid uv]$.

Also solved by R. H. Anglin, J. W. Baldwin, W. Bluger, Michael Goldberg. D. M. Hancasky, J. A. H. Hunter, Sam Kravitz, L. I. Lowell, D. C. B. Marsh, Liselotte Miller, Norman Miller, C. S. Ogilvy, J. S. Vigder, and the proposer.

Only Hunter and Kravitz answered the first question of the problem. Using the notation of the above solution we have

$$2x, 2y = e + w \pm \sqrt{(w + e)(w - 3e)},$$

where

$$w = \sqrt{(e^2 + z^2)} = (x^2 + xy + y^2)/(x + y).$$

An Identity in Binomial Coefficients

E 1833 [1965, 1022]. *Proposed by Alan Sutcliffe, Congleton, Cheshire, England*

If $m=\min(r, s)$ and $M=\max(r, s)$, prove that

$$\sum_{r=0}^{N}\sum_{s=0}^{N}\frac{(N+m)!}{r!s!(N-M)!}=\sum_{r=0}^{N}\frac{(N+r+1)!}{r!(r+1)!(N-r)!}.$$

Solution by David Zeitlin, Minneapolis, Minn. Rewrite the proposed identity as

$$\sum_{r=0}^{N}\sum_{s=0}^{N}\binom{N}{M}\binom{N+m}{m}=\sum_{r=0}^{N}\binom{N+1}{r+1}\binom{N+r+1}{r}.$$

We will use several well-known and easily proved relations on binomial coefficients:

$$\binom{N}{r}+\binom{N}{r+1}=\binom{N+1}{r+1}, \quad \sum_{s=0}^{r}\binom{N+s}{s}=\binom{N+r+1}{r},$$

$$\sum_{r=0}^{N}\binom{N+r}{r}\sum_{s=r+1}^{N}\binom{N}{s}=\sum_{r=0}^{N}\binom{N}{r+1}\sum_{s=0}^{r}\binom{N+s}{s}$$

$$=\sum_{r=0}^{N}\binom{N}{r+1}\binom{N+r+1}{r}.$$

Using the above and replacing m, M by their values, the desired result is proved

in the following steps:

$$\sum_{r=0}^{N}\binom{N}{r}\sum_{s=0}^{r}\binom{N+s}{s}+\sum_{r=0}^{N}\binom{N+r}{r}\sum_{s=r+1}^{N}\binom{N}{s}$$
$$=\sum_{r=0}^{N}\binom{N}{r}\binom{N+r+1}{r}+\sum_{r=0}^{N}\binom{N}{r+1}\binom{N+r+1}{r}$$
$$=\sum_{r=0}^{N}\binom{N+1}{r+1}\binom{N+r+1}{r}.$$

Also solved by L. Carlitz, P. A. Scheinok, and the proposer.

An Instance of a Ramanujan Result

E 1834 [1965, 1022]. *Proposed by Douglas Lind, University of Virginia*

Prove that

$$\pi=\sqrt{\{r+r'+2\sqrt{[2r+r'+3\sqrt{(3r+r'+\cdots)}]}\}},$$

where $r=\pi-3$ and $r'=r^2+3r+1$.

Solution by J. L. Standig, Alexandria, Va. With $r=\pi-3$ and $r+r'=\pi^2-2\pi-2$, we note that

$$\pi+n+1\equiv\frac{(\pi+n)^2-[r(n+1)+r']}{n+2}$$

for $n=0, 1, \cdots$, so that

$$\pi+n=\sqrt{\{r(n+1)+r'+(n+2)(\pi+n+1)\}}. \tag{*}$$

Now, for $n=0$, $\pi=\sqrt{\{r+r'+2(\pi+1)\}}$. In this, replace $\pi+1$ by its value from (*) with $n=1$ to get

$$\pi=\sqrt{\{r+r'+2\sqrt{[2r+r'+3(\pi+2)]}\}}.$$

We now replace $\pi+2$ using (*) and repeat as often as we please, to obtain the desired result.

Also solved by R. O. Davies & A. Weinmann (England), P. G. Kirmser, and the proposer.

Editorial Note. The proposer refers to Ramanujan, *Collected Papers*, Cambridge, 1927, p. 323:

$$n(n+k)=n\sqrt{\{(k-2)n+k''+(n+1)\sqrt{[(k-2)(n+1)+k''}}$$
$$+(n+2)\sqrt{\{(k-2)(n+2)+k''+\cdots\}]\}},$$

where $k''=k^2-k-1$, and this is the proposed relation with $k=\pi-1$, $n=1$, $r=k-2$. Ramanujan, however, gives only formal justification (similar to that provided in the above solution).

Davies and Weinmann offer the following proof that the successive replacements for $\pi+1$, $\pi+2$, etc., do indeed give a convergent sequence whose limit is π. Let

$$T_n=\sqrt{\{r+r'+2\sqrt{[2r+r'+3\sqrt{\{\cdots+(n-1)\sqrt{[(n-1)r+r'+n\sqrt{(nr+r'+n+1)}]\}}]\}}}.$$

We have from Standig's solution:

$$\pi = \sqrt{\{r + r' + 2\sqrt{[2r + r' + 3\sqrt{\{ \cdots + (n-1)\sqrt{[(n-1)r + r' + n\sqrt{\{nr + r' + (n+1)(\pi + n)\}}]}\}}]}}.$$

Therefore $T_n < \pi$ for all n. On the other hand,

$$\begin{aligned}(n+\pi)^{2^{-n}} T_n &= (n+\pi)^{2^{-n}} \sqrt{\{r + r' + 2\sqrt{[\cdots + (n-1)\sqrt{\{(n-1)r + r + n\sqrt{(nr + r' + n + 1)}\}}]}\}} \\ &= \sqrt{\{(n+\pi)^{2^{-n+1}}(r + r') + 2\sqrt{[(n+\pi)^{2^{-n+2}}(2r + r') + 3\sqrt{\{\cdots + (n-1)\sqrt{[(n+\pi)^{2^{-1}}((n-1)r + r') + n\sqrt{(n+\pi)(nr + r' + n + 1)}]}\}}]}\}} \\ &\geqq \sqrt{\{r + r' + 2\sqrt{[\cdots (n-1)\sqrt{\{(n-1)r + r' + n\sqrt{[nr + r' + (n+1)(n+\pi)]}\}}]}\}} = \pi.\end{aligned}$$

Thus $T_n \geqq \pi/(n+\pi)^{2^{-n}} \to \pi$ as $n \to \infty$. Thus $T_n \to \pi$ as required.

ADVANCED PROBLEMS

All solutions of Advanced Problems should be sent to J. Barlaz, Rutgers—The State University, New Brunswick, N. J. 08903. Solutions of Advanced Problems in this issue should be typed or written legibly on separate, signed sheets and should be mailed before September 30, 1967. ***Contributors (in the United States) who desire acknowledgement of receipt of their solutions are asked to enclose self-addressed stamped postcards.***

5470. *Proposed by Edwin Hewitt, University of Washington*

Let $(X, \mathfrak{A}, \mu)$ be a measure space such that if $A \in \mathfrak{A}$ and $\mu(A) = \infty$, then there is a set $B \in \mathfrak{A}$ such that $B \subset A$ and $0 < \mu(B) < \infty$. Let p be a real number such that $p > 1$ and let f be a complex-valued $\mathfrak{A}$-measurable function on X such that $f \notin \mathfrak{L}_p(X, \mathfrak{A}, \mu)$. Let $p' = p/(p-1)$. Prove that the set $\{\phi \in \mathfrak{L}_{p'}(X, \mathfrak{A}, \mu) : f\bar{\phi} \in \mathfrak{L}_1, \int_X f\bar{\phi}\, d\mu = 0\}$ is dense in $\mathfrak{L}_{p'}(X, \mathfrak{A}, \mu)$.

5471. *Proposed by W. A. McWorter, University of British Columbia*

Let G be a group and let σ be a nontrivial automorphism of G, such that for each $x \in G$, $\sigma(x) = x$ or $\sigma(x) = x^{-1}$. Prove that G is solvable.

5472. *Proposed by James Duemmel, University of Montana*

Let $J_n(x)$ be the Bessel function of the first kind of order n, $n \geqq 0$. Let $J_n'(\lambda) = 0$, $\lambda > 0$. Prove that $\lambda > n$.

5473. *Proposed by A. A. Goldstein and J. V. Ryff, University of Washington*

Let $F(r) = r^2 + 1$. Let $[,]$ represent an inner product, with $\|x\|^2 = [x, x]$. Prove that for any real number r, and any x, y with $\|x\| \geqq \|y\|$,

$$\|x\|^{2r} + \|y\|^{2r} - 2\|x\|^r\|y\|^r \frac{[x, y]}{\|x\| \cdot \|y\|} \leqq \begin{cases} \|x\|^{2r-2}\|x - y\|^2 F(r), & r \geqq 1, \\ \|y\|^{2r-2}\|x - y\|^2 F(r), & r < 1. \end{cases}$$

5474. *Proposed by Benjamin Volk, Far Rockaway, N. Y.*

Given an integer x and a sequence $\{\lambda_n\}$, $\lambda_0=1$, $\lambda_k\neq 0$. Define the $\{\lambda_n\}$ kth power of x, $x^{(k)}_{\{\lambda_n\}}=x^{(k)}$ by

$$0^{(k)}=\begin{cases}1, & k=0,\\ 0, & k>0,\end{cases}\qquad \frac{(x+1)^{(k)}}{\lambda_0\lambda_1\cdots\lambda_k}=\sum_{j=0}^{k}\frac{x^{(k-j)}}{\lambda_0\lambda_1\cdots\lambda_{k-j}}\cdot\frac{1^{(j)}}{\lambda_0\lambda_1\cdots\lambda_j}.$$

Then prove

$$\frac{(x+y)^{(k)}}{\lambda_0\lambda_1\cdots\lambda_k}=\sum_{j=0}^{k}\frac{x^{(k-j)}}{\lambda_0\lambda_1\cdots\lambda_{k-j}}\cdot\frac{y^{(j)}}{\lambda_0\lambda_1\cdots\lambda_j}.$$

This generalizes a result in Gloria Olive, *Generalized Powers*, this MONTHLY, 72 (1965) 619–627.

5475. *Proposed by Louis Comtet, Viroflay, France*

Let s be an integer >0, E an at most countable set, and $\mathfrak{V}$ a system of subsets of E which has the property that each member of E is a member of at most s sets of $\mathfrak{V}$. What can be said about Card $\mathfrak{V}$?

5476. *Proposed by W. A. McWorter, University of British Columbia*

Let $I=\{1,\cdots,n\}$. Let T be a subset of $I\times I$. Define M_T to be the set of all $n\times n$ matrices $A=(a_{ij})$ over a field F such that (i,j) in $I\times I\setminus T$ implies $a_{ij}=0$ in F. Characterize all T such that M_T is a subalgebra of the complete $n\times n$ matrix algebra over F.

5477. *Proposed by D. J. Newman, Yeshiva University*

Let $|\alpha|=1$. Show that there is a nontrivial bounded variation function, $f(x)$, on $[0,1]$ which satisfies $\alpha f(x)=f(x/2)+f((x+1)/2)$.

5478. *Proposed by Benjamin Volk, Far Rockaway, N. Y.*

Let $F(z)=\sum_{n=0}^{\infty}a_nz^n$ be analytic for $|z|<1$, and let $\{F(x_n)\}_{n=0}^{\infty}$ form a convergent sequence for some sequence of nonnegative reals $\{x_n\}$ converging to 1. If $\{a_n\}$ lies in some central sector of the closed unit disk of angle less than π, prove that $\sum_{n=0}^{\infty}|a_n|<\infty$.

5479. *Proposed by Fred Richman and John Thomas, New Mexico State University*

Let N be an odd integer. Can a rectangle be dissected into N nonoverlapping triangles, all having the same area?

SOLUTIONS OF ADVANCED PROBLEMS

The Coefficients of $(\sum c_ix^i)^n$

5325 [1965, 913; 1966, 901]. *Proposed by D. J. Newman, Yeshiva University, and W. E. Weissblum, AVCO Research*

Suppose $0 \leqq c_i \leqq 1$ and $\sum c_i = 2$. Prove that all the coefficients of $(\sum c_i x^i)^n$ are $\leqq \binom{n}{q}$, where $q = [n/2]$.

Editorial Note. Solution I, as given, is invalid since $2\binom{n}{q} \geqq \binom{n+1}{q}$. The solver, and the editors, offer apologies.

The First Zero of $\int_1^\infty \cos xt\, d\mu(x)$

5367 [1966, 206]. *Proposed by D. J. Newman, Yeshiva University*

Let $d\mu(x)$ be any finite positive measure and set $\phi(t) = \int_1^\infty \cos xt d\mu(x)$. Prove that $\phi(t)$ must have a zero in $[0, \pi]$. Prove also that π cannot be replaced by any smaller number.

Solution by the proposer. This problem arises in working with "Band Pass" signals. The first part of the problem follows easily from the evaluation of $I = \int_0^\pi \sin t\phi(t)dt$. Reversing integrations, it follows that

$$I = \int_1^\infty \frac{1 + \cos \pi x}{1 - x^2} d\mu(x) \leqq 0.$$

Now $\phi(0) \geqq 0$, and so $\phi(t)$ must vanish in $[0, \pi]$.

To obtain the second part of the problem consider the measure function defined by placing masses $1, \rho, \rho^2, \cdots$ at the points $1, 3+\epsilon, 5+2\epsilon, \cdots$, respectively $(0 < \rho < 1, \epsilon > 0)$. Then

$$\phi(t) = \sum_{k=0}^{\infty} \rho^k \cos t[k(2 + \epsilon) + 1] = \frac{\cos t - \rho \cos(1 + \epsilon)t}{1 + \rho^2 - 2\rho \cos(2 + \epsilon)t}.$$

With ρ chosen close to 1, the first positive zero of the numerator of $\phi(t)$ is pushed close to $2\pi/(2+\epsilon)$ which can be taken arbitrarily close to π.

Lattice Points within Curves of Constant Width

5368 [1966, 206]. *Proposed by Joseph Hammer, University of Sidney, Australia*

A curve of constant width greater than $\pi/(\pi - \sqrt{3})$ contains a lattice point.

Solution by G. D. Chakerian, University of California at Davis. If K is a curve with constant width b, perimeter L, and area A, then $L = \pi b$ (Barbier's theorem), and $A \geqq (\pi - \sqrt{3})b^2/2$ (Blaschke-Lebesgue theorem). Thus, with $b = \pi/(\pi - \sqrt{3})$, we obtain $L/2A \leqq 1$, so by a theorem of E. A. Bender (this MONTHLY, 69 (1962) 742–744), K contains a lattice point.

However, one can do better than this, since any set of constant width b contains a circle of radius $(1 - 1/\sqrt{3})b$ (H. G. Eggleston, *Convexity*, Cambridge 1958, p. 125), and any circle of diameter $> \sqrt{2}$ contains a lattice point. Thus K contains a lattice point if $b \geqq (\sqrt{6} + 3\sqrt{2})/4$. The same kind of argument shows that a body of constant width $b \geqq \{(2n+2)\sqrt{n} + n\sqrt{(2n+2)}\}/2(n+2)$ in Euclidean n-space contains a lattice point. (Note that the constant is asymptotic

to $\sqrt{n}(1+1/\sqrt{2})$.) We offer the question as to what is the smallest value of b for each dimension.

Also solved by G. R. Lyndaker, Andy Vince, and the proposer.

Determinant Type Functions of Infinite Matrices

5369 [1966, 206]. *Proposed by Albert Wilansky, Lehigh University*

Let M be the set of infinite matrices of real numbers each of which is row finite and column finite (i.e., each row and column has finitely many nonzero entries).

Let $f: M \to$ Reals satisfy $f(I)=1$, $f(AB)=f(BA)$.

Show that $\{A: f(A)=1\} \not\subset G$, where G is the set of invertible members of M. (The result is false for finite matrices of fixed order.)

Solution by James Washenberger, Iowa State University. Let the infinite matrices A and B be defined by $A=(\delta_{i+1,j})$ and $B=(\delta_{i,j+1})$ where $\delta_{n,m}$ is the Kronecker delta and $i, j=1, 2, \cdots$. Then $AB=I$ but $BA \neq I$. In fact, since the first column of BA consists entirely of zeros, BA is not a member of G. Let $C=BA$, then $f(C)=f(BA)=f(AB)=f(I)=1$. Thus C is a member of $\{A: f(A)=1\}$ but C is not in G.

Also solved by Roy O. Davies (England), J. T. Rosenbaum, W. R. Scott, G. N. Wollan, and the proposer. Davies observes that BA can never be inverted if $AB=I \neq BA$. Clearly, therefore, the situation in this problem is peculiar to infinite matrices.

Nilpotent Rings

5371 [1966, 311]. *Proposed by W. A. McWorter, University of British Columbia*

Let R be a ring finitely generated by $x_1, \cdots, x_n$. Suppose that every x_i is nilpotent in R and R satisfies the identity $xyx+yxy=0$ for every x and y which are products of the x_i (x and y monomials in the x_i). Prove that R is nilpotent. (R nilpotent means that for some m every product of m elements vanishes.)

Solution by W. G. Leavitt, University of Nebraska. For any j

$$x_j^2 x_j^2 = -x_j^2 x_j x_j^2 = -x_j^5.$$

Thus $x_j^4 = \pm x_j^m$ for any $m \geqq 4$, so, since x_j is nilpotent, $x_j^4=0$. Similarly (for any i, j) $w=x_i(x_jx_ix_j)x_i=-x_jwx_j$. Thus $w=x_j^4wx_j^4=0$ and so $(x_ix_j)^3=0$.

Now, for any i, j, k we have

$$u = x_ix_jx_kx_i = -x_j(x_kx_ix_jx_k) = x_jx_ix_jx_kx_ix_j = x_jux_j.$$

Thus, again, $u=0$. Similarly, for any i, j, k, r,

$$v = x_ix_jx_kx_rx_i = -x_jx_k(x_rx_ix_jx_kx_r) = x_jx_kx_ix_jx_kx_rx_ix_jx_k = x_jx_kvx_jx_k.$$

Thus, since $(x_jx_k)^3=0$, we have $v=0$.

Proceeding similarly we find that $x_iux_i=0$ in all cases in which u is a product of two or more symbols. But in every product of $3n+1$ or more symbols some

symbol, say x_i, must appear at least 4 times. The product must then contain x_i^4 or it must contain x_iux_i where u has at least two symbols. Thus every product of $3n+1$ or more symbols is zero.

Also solved by Anders Bager (Denmark), K. E. Eldridge, Erwin Just, Ka Menehune, F. C. Stewart, G. N. Pandya, and the proposer.

Linear Factors in a Polynomial

5372 [1966, 311]. *Proposed by L. Carlitz, Duke University*

Let p be a prime >2. Show that the polynomial $P(x)=x^{p+1}-\frac{1}{2}x^2-2c$ has linear factors (mod p) if and only if c is a quadratic residue (mod p). Moreover, when linear factors occur each has multiplicity two.

I. *Solution by E. S. Langford, U. S. Naval Postgraduate School.* a is a zero of P iff $a^{p+1}-\frac{1}{2}a^2-2c\equiv\frac{1}{2}a^2-2c\equiv 0$; that is, a is a zero of P iff $a^2\equiv 4c$, which is obviously true iff c is a quadratic residue (mod p).

If $c=0$, then $P(x)=x^2Q(x)$, where $Q(x)=x^{p-1}-\frac{1}{2}$. Q is obviously irreducible, by Fermat's theorem.

Suppose then that $c\not\equiv 0$ is a quadratic residue. Write $c=(a/2)^2$. Then $x=+a$ and $x=-a$ will be the only zeros of P. It can be verified that

$$P(x) = (x-a)^2(x+a)^2Q(x),$$

where $Q(x)=x^{p-3}+2a^2x^{p-5}+3a^4x^{p-7}+\cdots+\frac{1}{2}(p-1)a^{p-3}$. But

$$Q(a) \equiv Q(-a) \equiv (1+2+\cdots+\tfrac{1}{2}(p-1))a^{p-3} \equiv \frac{(p-1)(p+1)a^{p-3}}{8}$$

$$\equiv -\frac{a^{p-3}}{8}.$$

This cannot be zero, so Q is irreducible.

II. *Solution by J. B. Muskat, University of Pittsburgh.* For $P(x)$ we find $P'(x)=(p+1)x^p-x\equiv 0$ and $P''(x)\equiv -1$ for all x, showing that linear factors occur with exact exponent 2.

Also solved by Anders Bager (Denmark), J. L. Brenner, M. S. Demos, H. M. Edgar, M. A. Ettrick, M. G. Greening (Australia), John B. Kelly, Kenneth Kramer, W. A. McWorter, H. F. Mattson, Jr., Ka Menehune, Charles Wells, K. S. Williams, (England), and the proposer.

Wells shows that the result is still valid if p is replaced by p^n and the polynomial is taken over GF(p^n) with c a square in GF(p^n).

Almost every contributor noticed the misprinted sign of the term $2c$ in the original statement [1966, 311]. The result when $P(0)=2c$ does not hold unless $p\equiv 1$ (mod 4).

Irreducible Quadratic Factors over GF(p^n)

5373 [1966, 312]. *Proposed by L. Carlitz, Duke University*

Let p be a prime >2.

(a) Show that $x^{p+1}+ax+b$, where $a\not\equiv 0 \pmod{p}$, has no irreducible quadratic factor (mod p).

(b) Show that $x^{p+1}+ax^2+b$, where $ab\not\equiv 0 \pmod{p}$, has an irreducible quadratic factor (mod p) if and only if $(1-a)b$ is a quadratic nonresidue (mod p).

Solution by Charles Wells, Western Reserve University. Let $q=p^n$, p an odd prime, n a positive integer. We consider the polynomials $f(x)=x^{q+1}+ax+b$ ($a, b\in \mathrm{GF}(q)$, $a\neq 0$) and $g(x)=x^{q+1}+ax^2+b$ ($a, b\in \mathrm{GF}(q)$, $ab\neq 0$).

(a) If f has an irreducible quadratic factor, then it has a root $r\in \mathrm{GF}(q^2)$ which has the property that $r^{q^2}=r$ but $r^q\neq r$. But then $r^{q+1}=-ar-b$, and, raising this to the qth power, $r^{q+1}=-ar^q-b$ since $a^q=a$, $b^q=b$. Then $ar+b=ar^q+b$, $r=r^q$, a contradiction.

(b) If g has an irreducible quadratic factor, then it has a root r as in (a). Then, as in (a), it follows that $ar^{2q}+b=ar^2+b$, so that $r^{2q}=r^2$. Since $r^q\neq r$, this means $r^q=-r$. Hence $-r^2=r^{q+1}$, and since $g(r)=0$, $-r^2+ar^2+b=0$. But this means $r^2=b(1-a)^{-1}$. Thus $b(1-a)^{-1}$, and therefore $b(1-a)$, cannot be a square in $\mathrm{GF}(q)$ since $r\notin \mathrm{GF}(q)$.

Conversely, if $b(1-a)$ is not a square in $\mathrm{GF}(q)$, then we may write $b(1-a)^{-1}=r^2$, $r\in \mathrm{GF}(q^2)$, and $r^q\neq r$. But $r^2\in \mathrm{GF}(q)$, so $r^{2q}=r^2$. Then $(r^{q+1})^2=r^{2q}\cdot r^2=r^4$, so $r^{q+1}=\pm r^2$. Since $r^q\neq r$, $r^{q+1}=-r^2$. Then $g(r)=-r^2+ar^2+b=-b(1-a)^{-1}+ab(1-a)^{-1}+b=-b+b=0$, thus yielding the irreducible quadratic factor x^2-r^2.

Also solved by M. A. Ettrick, M. G. Greening (Australia), Kenneth Kramer, H. F. Mattson, Jr., W. A. McWorter, Ka Menehune, and the proposer.

Sequences almost Linearly Related

5374 [1966, 312]. *Proposed by Benjamin Volk, Far Rockaway, N. Y.*

Under what conditions for $\{a_n\}$, $\{b_n\}$ may we find nontrivial A, B such that $\lim\{Aa_n+Bb_n\}$ exists?

Solution by Robert Goldstein, The Northern Polytechnic, London, England. We first note the trivial cases:

1. If $A=B=0$, then for any pair of sequences $\{a_n\}$, $\{b_n\}$, the sequence $\{Aa_n+Bb_n\}$ converges to zero.

2. If one of A, B may be zero, then $\{Aa_n+Bb_n\}$ converges if one of $\{a_n\}$, $\{b_n\}$ converges (with suitable choice of A, B).

In what follows we require $A\neq 0$, $B\neq 0$. We then prove that the necessary and sufficient condition for the existence of nontrivial A, B such that $\{Aa_n+Bb_n\}$ is convergent, is that there exist P, Q ($P\neq 0$) such that $b_n=Pa_n+Q+\epsilon_n$, where ϵ_n denotes a sequence which tends to zero as $n\to\infty$.

(i) The condition is necessary. Given that $\{Aa_n+Bb_n\}$ converges, we have $Aa_n+Bb_n=c+o(1)$, so $b_n=(-A/B)a_n+(c/B)+o(1)$. Hence $P=-A/B$, $Q=c/B$.

(ii) The condition is sufficient. Let $b_n = Pa_n + Q + o(1)$. Choose $A = -P$, $B = 1$, then $Aa_n + Bb_n = Q + o(1)$ which converges to Q as $n \to \infty$.

It is easily seen that (a) α is a limit point of $\{a_n\}$ if and only if $\beta = P\alpha + Q$ is a limit point of $\{b_n\}$; and (b) $b_n/a_n \sim P$ as $n \to \infty$ through T, where T is an increasing subsequence of the natural numbers such that $a_n \to \infty$, $b_n \to \infty$ as $n \to \infty$ through T.

These results may be used to obtain necessary conditions on $\{a_n\}$ and $\{b_n\}$ to fulfill the requirements of the problem. Thus, (a) yields the result that the linear function $y = Px + Q$ sets up a one-one correspondence between the set of limit points of $\{a_n\}$ and that of $\{b_n\}$. Moreover, $\{a_n\}$ is bounded if and only if $\{b_n\}$ is bounded.

For bounded sequences with a finite number of limit points, we have: Let $\alpha_1 < \alpha_2 < \cdots < \alpha_k$ be the limit points of the bounded sequence $\{a_n\}$ and $\beta_1 < \beta_2 < \cdots < \beta_k$ be the limit points of the bounded sequence $\{b_n\}$. Then the necessary condition for the existence of nontrivial A, B such that $\{Aa_n + Bb_n\}$ converges is that one of the systems of linear equations in P and Q given by

$$\beta_i = P\alpha_i + Q \qquad (i = 1, 2, \cdots, k) \tag{1}$$

$$\beta_{k-i+1} = P\alpha_i + Q \qquad (i = 1, 2, \cdots, k) \tag{2}$$

is consistent.

If $k = 1$, i.e. $\{a_n\}$ and $\{b_n\}$ are both convergent, these conditions become vacuous. Indeed, in this case, for any A, B, $\{Aa_n + Bb_n\}$ converges.

The Sequence $a_{n+1} = a_n(1 - a_n^2)$

5375 [1966, 312]. *Proposed by Benjamin Volk, Far Rockaway, N. Y.*

Given a sequence of real numbers $\{a_n\}$ satisfying $0 < a_1 < 1$, $a_{n+1} = a_n(1 - a_n^2)$. Clearly $a_n \downarrow 0$. For which α is it true that $a_n = O(n^{-\alpha})$? How finely may we estimate the convergence of $\{a_n\}$?

I. *Solution by Sidney Spital and Yu Chang, California State Polytechnic College, Pomona.* In L. M. Milne-Thompson, *Calculus of Finite Differences*, 1960, p. 342, we find the given difference equation treated via Haldene's method. There it is found that

$$a_n^2 = \frac{1}{2n}\left[1 + 3a_n^2 \log a_n + O(a_n^2)\right] \qquad (n \nearrow \infty,\ a_n \searrow 0) \tag{1}$$

which shows that we may write

$$a_n = 1/\sqrt{2n(1 + \epsilon_n)}, \qquad \text{where } \epsilon_n \to 0. \tag{2}$$

Substitution of (2) into (1) gives, after slight rearrangement,

$$2n = 2n(1 + \epsilon_n) - \tfrac{3}{2}(\log n - \log(1 + \epsilon_n)) + O(1).$$

Invoking $\log(1+\epsilon_n)=O(1)$, we find $\epsilon_n=3\log n/4n+O(1/n)$. Hence, after binomial expansion of $1/\sqrt{(1+\epsilon_n)}$,

$$a_n=\frac{1}{\sqrt{2n}}-\frac{3}{8\sqrt{2}}\cdot\frac{\log n}{n^{3/2}}+O\left(\frac{1}{n^{3/2}}\right).$$

II. *Solution by I. N. Baker, Imperial College, London, England.* In Fatou, *Sur les équations fonctionnelles*, Bull. Soc. Math. de France, 47 (1919) 161–271, Section 11, the general case

$$z_{n+1}=z_n-az_n^{p+1}+\cdots, \qquad a>0,$$

is discussed, and it is shown that for z_1 in a suitable region (e.g., $0<|z|<\delta$, $|\arg z|<\pi/p-\epsilon$) one has $z_n=\{npa+O(n^{1-1/p})\}^{-1/p}$. Thus in our example,

$$a_n=\{2n+O(n^{1/2})\}^{-1/2}$$

for $0<a_1<\delta$ in the first instance, and in fact in $0<a_1<1-\epsilon$ for any ϵ, since $a_n\downarrow 0$.

Also solved by Leopold Flatto, Robert Goldstein (England), Amram Meir, and George Piranian.

A Problem in Convergence of Infinite Series

5376 [1966, 312]. *Proposed by Jürgen Elstrodt, University of Münster, West Germany*

Denote by $\log_p x$ the p-fold iterated natural logarithm of x ($\log_1 x=\log x$, $\log_{p+1}x=\log(\log_p x)$). Abel has shown that the infinite series

$$\sum_{n=N}^{\infty}\frac{1}{n\log n\cdots\log_{p-1}n(\log_p n)^{\alpha}}$$

(N sufficiently great, p a fixed natural number) converges if $\alpha>1$ and diverges if $\alpha\leqq 1$. Now let p increase with n, define $p(n)$ for $n\geqq 3$ by $1<\log_{p(n)}n\leqq e$, and prove that the infinite series

$$\sum_{n=3}^{\infty}\frac{1}{n\log n\cdots\log_{p(n)}n} \tag{1}$$

diverges. Prove also that the infinite series

$$\sum_{n=9}^{\infty}\frac{1}{n\log n\cdots\log_{q(n)-1}n(\log_{q(n)}n)^{\alpha}} \tag{2}$$

with $q(n)=[\frac{1}{2}p(n)]$ converges if $\alpha>1$ and diverges if $\alpha\leqq 1$. (For real x we denote by $[x]$ the unique integer satisfying $[x]\leqq x<[x]+1$.)

Solution by Addison Fischer, Student, Washington Irving High School, Clarksburg, W. Va. First of all, let us introduce the function $\epsilon(p)$ defined in this manner:

$\epsilon(0)=1$; $\epsilon(p+1)=e^{\epsilon(p)}$. Since $\log_p \epsilon(p)=1$ and $\log_p \epsilon(p+1)=e$, then for $\epsilon(p)<n \leqq \epsilon(p+1)$ we have $p(n)=p$. Similarly, for $\epsilon(2p)<n\leqq\epsilon(2p+2)$, $q(n)=p$.

The series (1) converges if and only if the sequence of partial sums

$$\sum_{n=3}^{[\epsilon(k+1)]} \frac{1}{n \log n \cdots \log_{p(n)} n}$$

does. This partial sum is equivalent to

$$\sum_{i=1}^{k} \sum_{n=[\epsilon(i)]+1}^{[\epsilon(i+1)]} \frac{1}{n \log n \cdots \log_i n} > \sum_{i=1}^{k} \int_{[\epsilon(i)]+1}^{\epsilon(i+1)} \frac{dx}{x \log x \cdots \log_i x}$$

$$= \sum_{i=1}^{k} \{\log_{i+1} x\}_{[\epsilon(i)]+1}^{\epsilon(i+1)} > \sum_{i=1}^{k} (1 - \log 2);$$

where the last step is a result of the inequality

$$\log_{i+1}([\epsilon(i)]+1) = \log_{i+1}([e^{\epsilon(i-1)}]+1) < \log_{i+1}(2e^{\epsilon(i-1)})$$

$$= \log_i (\log 2 + \epsilon(i-1)) < \log_i (1+\epsilon(i-1)) \leqq \cdots \leqq \log_b (1+\epsilon(b-1))$$

$$\leqq \cdots \leqq \log 2, \qquad i \geqq b \geqq 1.$$

Hence, clearly, the series diverges.

In case $\alpha \leqq 1$, the series (2) is not less than

$$\sum_{n=9}^{\infty} \frac{1}{n \log n \cdots \log_{q(n)-1} n \cdot \log_{q(n)} n} > \sum_{n=9}^{\infty} \frac{1}{n \log n \cdots \log_{q(n)} n \cdots \log_{p(n)} n}$$

which diverges because of (1).

In determining the convergence of this series for $\alpha>1$ we need only consider

$$\sum_{n=16}^{\infty} \frac{1}{n \log n \cdots \log_{q(n)-1} n (\log_{q(n)} n)^{\alpha}}$$

$$= \sum_{n=1}^{\infty} \sum_{m=[\epsilon(2n)]+1}^{[\epsilon(2n+2)]} \frac{1}{m \log m \cdots \log_{n-1} m (\log_n m)^{\alpha}}$$

$$< \sum_{n=1}^{\infty} \int_{[\epsilon(2n)]}^{\epsilon(2n+2)} \frac{dx}{x \log x \cdots (\log_n x)^{\alpha}} = -\frac{1}{\alpha-1} \sum_{n=1}^{\infty} \left\{ \frac{1}{(\log_n x)^{\alpha-1}} \right\}_{[\epsilon(2n)]}^{\epsilon(2n+2)}$$

$$< \frac{1}{\alpha-1} \sum_{n=1}^{\infty} \frac{1}{(\log_n [\epsilon(2n)])^{\alpha-1}} < \frac{1}{\alpha-1} \sum_{n=1}^{\infty} \frac{1}{(\log_n \epsilon(2n-1))^{\alpha-1}}$$

$$= \frac{1}{\alpha-1} \sum_{n=0}^{\infty} \frac{1}{(\epsilon(n))^{\alpha-1}} < \frac{1}{\alpha-1} \sum_{n=0}^{\infty} \frac{1}{(e^{\alpha-1})^n};$$

since $\epsilon(n) \geqq e^n$ (equality iff $n=0$ or 1). This last series is convergent, hence our proof is complete.

Also solved by Robert Goldstein (England), Sidney Spital, Dieter Wolke (Germany), and the proposer.

Wolke noted that the method used to prove the divergence of (1) may also be used to prove the divergence of

$$\sum_{n=n_0}^{\infty} \frac{1}{n \log n \cdots \log_{p(n)-k-1} n \cdot (\log_{p(n)-k} n)^a}$$

in which k is any fixed positive integer and a is real. He raises the question as to the required magnitude of $f(n)$ to secure convergence properties for

$$\sum_{n=n_0}^{\infty} \frac{1}{n \log n \cdots \log_{p(n)-f(n)-1} n \cdot (\log_{p(n)-f(n)} n)^a}$$

analogous to the results for (2), and he observes that the methods used for (2) allow $f(n)=[\log_k p(n)]$ for any fixed positive integer k.

On Commutative Rings

5377 [1966, 312]. *Proposed by Erwin Just and Norman Schaumberger, Bronx Community College*

In a ring R each element x satisfies the equation $x=x^{n+1}$ for some integer n. Prove that $x^n y=yx^n$ for each x and y contained in R.

I. *Solution by Sheila M. Kaye, McGill University.* We must assume $n\equiv n(x)>0$.

(a) $x^{n(x)}$ is idempotent, since $(x^{n(x)})^2=x^{n(x)+1}x^{n(x)-1}=x^{n(x)}$.

(b) Let $ab=0$. Then $ba=(ba)^{n(ba)+1}=b(ab)^{n(ba)}a=0$.

(c) Let x, $y\in R$ and let $n=n(x)$. Then from (a), $yx^n=yx^{2n}$, whence $(y-yx^n)x^n=0$. Also from (b), $x^n(y-yx^n)=0$, so that $x^ny=x^nyx^n$.

(d) Similarly, from $x^ny=x^{2n}y$, we deduce $yx^n=x^nyx^n$, which completes the proof.

II. *Solution by Harsh Pittie, Princeton University.* Actually much more is known. The condition $x^{m(x)}=x$, $m(x)>1$ implies that R is commutative (see N. Jacobson, *Structure Theories for algebraic algebras of bounded degree*, Annals of Math., 46 (1945), pp. 695 ff). The given condition may be replaced by $x^{m(x)}-x$ is in the center of R (I. N. Herstein, *A generalization of a theorem of Jacobson*, Amer. J. of Math., 73 (1951), pp. 756 ff). See also Ayoub and Ayoub, *On the commutativity of rings*, this MONTHLY, 71 (1964) 267–271.

Fundamentals of Digital Machine Computing. By Guenther Hintze. Springer, NewYork, 1966. ix+225 pp. $6.40. " . . . topics include the basic circuitry, logical organization and programming concepts common to all large modern computers. . . . This book was photo-offset by Linofil equipment activated by punched paper tape produced from an RCA 301 computer by means of programmed instructions created by Rocappi, Inc.," T, S, P.

Threshold Logic. By Sze-Tsen Hu. University of California Press, Berkeley, Cal., 1966. xiv+338 pp. $8.00. Threshold devices and related switching functions.

Introduction to Computing. By T. E. Hull. Prentice Hall, Englewood Cliffs, N. J., 1966. xi+212 pp. $7.50. Algorithms, stored-programs, basic programs, compilers and monitors, FORTRAN (80 pp.), planning and debugging, numerical methods, non-numerical applications, simulation, automata, languages. T (Introductory), S, P, L.

Tables of Lagrange Interpolation Coefficients. By K. A. Karpov. Translated by D. E. Brown. Pergamon Press, L. I. City, N. Y., 1965. viii+74 pp. $5.75. L.

The Method of Averaging Functional Corrections: Theory and Applications. By A. Yu. Luchka. Academic Press, New York, 1965. xvii+136 pp. $3.45 (paper). Approximating algorithms for integral, differential, integro-differential, and other equations. P.

Handbook for Computing Elementary Functions. By L. A. Lyusternik, O. A. Chervonenkis, and A. R. Yanpol'skii. Translated by G. J. Tee. Pergamon, L. I. City, N. Y. 1965. xiii+251 pp. $10.00. P, L.

Ten-Decimal Tables of the Logarithms of Complex Numbers and for the Transformation from Cartesian to Polar Coordinates, tables of the functions ln x, arctan x, $\frac{1}{2}$ ln $(1+X^2)$, $\sqrt{1+X^2}$. Edited by L. A. Lyusternik. Translated by D. E. Brown. Pergamon, L. I. City N. Y., 1965. ix+110 pp. $7.50.

An Introduction to Computer Programming. By Henry Mullish. Gordon and Breach, New York, 1966. xi+244 pp. $5.00 (paper) $14.50 (cloth). " . . . the essentials of programming for large scale electronic computers . . . to help create a substantial understanding of the techniques employed in solving many of today's common tasks . . . " FORTRAN used throughout. Coding sheets included. T (11–14), S (15–17), P.

A Fortran IV Primer. By E. I. Organick. Addison-Wesley, Reading, Mass., 1966. viii +263 pp. $4.95 (paper). T (12–18).

Numerical Mathematical Analysis. 6th ed. By James B. Scarborough. Johns Hopkins Press, Baltimore, 1966. xxi+608 pp. $8.50. This old standby, first published in 1930 and in successive editions in 1950, 1955, 1958, and 1962 is now enlarged slightly by "the addition of the trapezoid rule, an additional method of finding the roots of numerical equations, and formulas and computing schedules for the numerical solution of simultaneous differential equations of the second order by the Runge-Kutta method". S, P, L (if you don't have a recent edition).

Introduction to Numerical Analysis. By Gerard P. Weeg and Georgia B. Reed. Blaisdell, Waltham, Mass., 1966. vii+184 pp. $7.50. Errors, real roots of equations, polynomial approximations and finite differences, integration, ordinary differential equations, linear equations and matrices, least squares, Gaussian quadrature. T (14–15, one term course). S.

Theoretical Numerical Analysis. By Burton Wendroff. Academic Press, New York, 1966. xi+239 pp. $10.95. " . . . as a legitimate branch of mathematics . . . narrow, often deep path through . . . interpolation, approximation, numerical solution of ordinary and partial differential equations . . . systems of equations . . . a few computer problems . . . " T (17), P. (Reviewed in *American Scientist*, December 1966, 436A.)

Texts on Linear Algebra.

Matrices and Linear Transformations. By Charles Cullen. Addison-Wesley, Reading, Mass., 1966. 272 pp. $8.95. One or two term course for "science, engineering, and mathematics students . . . matrix theory point of view rather than . . . abstract approach . . . " T (14–15).

Elementary Matrix Theory. By Howard Eves. Allyn and Bacon, Boston, 1966. xvi+325 pp. $9.50 " . . . one-semester introduction . . . for the general student . . . the elementary, or concrete, approach is employed and no previous course in abstract algebra is required. Matrices are studied over the field of complex numbers . . . occasional references to . . . real numbers . . . and optional . . . extension to . . . abstract rings and fields . . . " T (14–15), TT.

Introduction to Matrices and Linear Transformations. By Daniel T. Finkbeiner, II. 2nd ed. Freeman, San Francisco, 1966. xi+297 pp. $7.75. Changes from first edition included earlier introduction of the dual space, use of cyclic subspaces in proofs of the Hamilton-Cayley theorem and the Jordan canonical form, more complete treatment of metric concepts, expanded discussion of combinatorial equivalence and applications to linear programming, and a new appendix on different matrix notations. T (14–15).

Linear Algebra. By Serge Lang. Addison-Wesley, Reading, Mass., 1966. x+294 pp. $8.95. For a semester or year course. Vectors in euclidean space, vector spaces, matrices as linear mappings, determinants, bilinear maps, polynomials and matrices, triangulation, spectral theorem, primary decomposition, multilinear products (tensors), groups, rings, convexity. T (14–15).

Matrices and Transformations. By Anthony J. Pettofrezzo. Prentice-Hall, Englewood Cliffs, N. J. 1966. x+133 pp. $3.95. Elementary definitions and consequences, linear transform atoms, eigenvalues and eigenvectors for training high school teachers. T (13–14).

Vector Spaces of Finite Dimension. By G. C. Shephard. Oliver & Boyd, London, 1966. viii+200 pp. $3.25 (from Wiley, the U. S. distributor). Linear algebra without ma-

trices and determinants followed by interpretation in matrix terms. Assumes the most elementary parts of abstract algebra, together with the properties of matrices and determinants. T (15–16), S.

Logic, Foundations, Philosophy.

The Undecidable: Basic papers on undecidable propositions, unsolvable problems and computable functions. Edited by Martin Davis. Raven Press, Hewlett, N. Y., 1965. 440 pp. $9.75. This anthology consists of papers by Gödel, Church, Turing, Rosser, Kleene and Post, most of which have been available heretofore only in the periodicals in which they originally appeared. A few, such as Gödel's Princeton Lectures, have not been published previously or appear here for the first time in English translation. P. L.

Symbolic Logic and the Real Number System. By A. H. Lightstone. Harper & Row, New York, 1965. ix+225 pp. $7.50. T (15), S, TT.

A Theory of Sets. By Anthony P. Morse. Academic Press, New York, 1965. xxxi+130 pp. $7.95. An original "formal unified treatment of logic and set theory." T (18–19), S, P, L.

Elementary Logic. By Willard Van Orman Quine. Harvard Univ., Cambridge, Mass., 1966. xii+129 pp. $3.50. Much revised from its first (1941) edition. T (15).

Selected Logic Papers. By W. V. Quine. Random, New York, 1966. x+250 pp. $6.95. Twenty-three technical papers on logic (1934–1960), including one historical and one survey paper. S (16–19), P, L.

The Ways of Paradox and other essays. By W. V. Quine. Random House, New York, 1966. x+258 pp. $6.95. Twenty-one papers (1934–1964) on logic, foundations, history and philosophy of mathematics, complementing his previous collections *From a Logical Point of View* and *Word and Object.* S (15–19), P, L.

Non-Standard Analysis. By A. Robinson. North Holland, Amsterdam, 1966. xi+293 pp. $10.00. Survey of the theory since its origin (1960) in the idea "that the concepts and methods of contemporary mathematical logic are capable of providing suitable framework for the development of the Differential and Integral Calculus by means of infinitely small and infinitely large numbers." Final chapter is on the history of calculus. P.

Number Systems of Analysis. By G. Cuthbert Webber. Addison-Wesley, Reading, Mass., 1966. x+213 pp. $7.95. From the natural through complex numbers from modified Peano via Cauchy sequences. T (14–15), S.

Probability and Statistics.

Ergodic Theory and Information. By Patrick Billingsley. Wiley, New York, 1965. xiii +193 pp. $8.50. First of a Series of Tracts on Probability and Mathematical Statistics "intended to make new mathematical developments generally accessible while the pulse of life still beats in them. . . . This book grew out of a survey . . . designed to follow a brief course in measure-theoretic probability . . . not for the experts, but for those to whom the subject is new." S, P.

An Introduction to Probability Theory and Its Applications. Vol. II. By William Feller. Wiley, New York, 1966. xviii+626 pp. $12.00. Similar to Vol. I. but "harder mathematics" including continuous distributions, measure, higher dimensional spaces, limit theorems, Markov processes, renewal theory, Laplace transform methods, etc. T (16–17), S, P, L.

Theory of Probability. By Bernard Harris (Univ. of Wisconsin). Addison-Wesley, Reading, Massachusetts, 1966. ix+294 pp. $9.75. Probability based on the Kolmogorov axioms, random variables and distributions, moments, random experiments, limit theorems. " . . . extensive use of characteristic functions and the Riemann Stieltjes integrals, so that the discrete and continuous cases may be treated simultaneously." T (15–16).

A First Course in Stochastic Processes. By Samuel Karlin. Academic Press, New York, 1966. xi+502 pp. $11.75. Assumes something like Feller's Volume I. T (16), S, P.

Introduction to Measure and Probability. By J. F. C. Kingman and S. J. Taylor. Cambridge Univ. Press, 1966. $12.50. Finite measures in general spaces (including Lebesgue and Lebesgue-Stieltjes) in chapters 1–6, introductory functional analysis in chapters 7–8, followed by probability, random variables, characteristic functions, independence, joint distributions, and stochastic processes in chapters 10–15. T (16–17), S, P.

Classical and Contagious Discrete Distributions. Proceedings of the International Symposium held at McGill University, Montreal, Canada, August 15–August 20, 1963. Edited by Ganapati P. Patil. Pergamon Press, L. I. City, 1965. xiv+552 pp. $21.00. P, L.

The Linear Hypothesis: A General Theory. By. G. A. Seber. Edited by M. G. Kendall. Hafner, New York, 1966. vii+115 pp. $4.15. Linear hypothesis theory (formerly "under the guise of regressional analysis, analysis of variance, and experimental design") in a vector space framework. S, P, L.

The Structure of Lie groups. By G. Hochschild. Holden-Day, San Francisco, London, Amsterdam, 1965. x+230 pp. $11.75.

This excellent introduction is not written for the innocent. The exposition is at the level of the well trained advanced graduate student or young Ph.D. who wishes to inform himself quickly of a vital area. For the nonexpert (e.g., the reviewer) the way is eased by the first 75 pages, the main theme appearing only in Chapter VII. Each chapter is well organized almost as an independent unit, and each is of just the right length, long enough to be informative and short enough to avoid discouraging the reader, and ends with two to six nontrivial problems. One wishes that the author would share his considerable expository talents (in, perhaps, a 350 page book) with a somewhat less knowledgeable audience.

F. HAIMO, Washington Univ., St. Louis

Differential Periodic Maps. By. P. E. Conner and E. E. Floyd. Academic Press, New York, 1966. 148 pp. $6.50.

This book represents almost all original research. The expository material present is extremely brief and condensed. Indeed, it is little more than a method of presenting notation. Hence, the reader is expected to have a substantial experience with the topics discussed in the book. These are by chapter headings: The bordism groups; Computation of the bordism groups; The G-bordism groups; Differentiable involutions; Differentiable actions of $(Z_2)^k$; Differentiable involutions and bundles; The structure of $\Omega_*(Z_p)$, p an odd prime; Fixed points of maps of odd prime period; Actions of finite abelian groups of odd prime power order.

LOUIS AUSLANDER, City Univ. of New York

Positive Solutions of Operator Equations. By. M. A. Krasnoselskii. Translated from the Russian by Richard E. Flaherty and edited by Leo F. Boron. Noordhoff, Groningen, 1964. 381 pp. $13.75.

"This book," according to its annotation, "is devoted to a systematic study of an important aspect of nonlinear functional analysis." The aspect referred to is the positivity of many standard nonlinear operators with respect to a cone in the space of definition. (A cone in a real Banach space E is a closed subset such that if $u,v \in K$ then $\alpha u+\omega v \in K$ for all $\alpha, \omega \geqq 0$ and if $u \neq 0$ is in E then either u or $-u$ is not in K.) The first two chapters discuss the geometry of Banach spaces with cones and linear operators which are positive with respect to the cone. (An operator is called positive if it maps K into K.) The next three chapters are devoted to theory of non-linear operators. They include Fréchet differentiation, fixed point theorems, eigenvectors, concave and convex operators, and successive approximation methods. The last chapter deals with applications of the previous theory to such topics as non-linear integral equations, non-linear elliptic boundary value problems, periodic solutions of ordinary differential equations and the Monge-Ampère equations.

Due to the inordinately large number of definitions, the reviewer found the book very tedious reading. There is a summary at the back of the book, however, which should allow a reader to open the book to, for example, the last chapter and read it with only a modicum of difficulty. The reviewer cannot see this book being used for a text in either an undergraduate or a graduate course, though it would make rather interesting material for a graduate or post-graduate seminar.

A. R. BRODSKY, University of California, Los Angeles

Elementary Abstract Algebra. By E. M. Patterson and D. E. Rutherford. Wiley, New York, 1965. viii+211 pp. $3.50.

The strength of R. Dedekind's abstractions in dealing with classical problems of algebra guided and inspired E. Noether to create a new method of expounding algebraic insights centered on concepts and their relations from which the solutions of solvable problems are derived. The first edition of "Moderne Algebra" by van der Waerden established the success of this method of exposition inasmuch as it reflected a much broader attitude towards algebraic relationships than the problem-centered approach of Dedekind's predecessors. In fact today, about forty years later, "modern algebra" has become "algebra" and a book on "elementary abstract algebra" providing a "thorough, but not too hurried, introduction to some of the basic ideas of abstract algebra" has become desirable and may indeed "be suitable for senior school pupils who wish to have a preview of the algebra they are likely to encounter at University." It follows that the choice of topics and the sequence in which they are expounded is determined exclusively by their usefulness towards learning and understanding abstract algebra, that only scant mention is given to the problems of number theory and geometry which led eventually to the evolution of concepts like binary operations (I), semi-groups, groups, permutations, isomorphisms, homomorphism (II), rings, integral domains, fields, matrices, characteristics, ideals and factorrings (III), polynomial and Euclidean rings, algebraic extensions of a field, algebraically closed fields (IV), vector spaces, unitary spaces, normed vector spaces, linear algebras and Lie algebras (V). It means also that there are no references whatever to the history of the subject—frequent references to other books in the same series take their place. On almost every page the text is remarkable for the care given to exposition and motivation of the concepts gradually brought into view. Marvels of careful exposition are, e.g., §23 on matrices and §34 on polynomials in a single indeterminate. Each chapter contains a few well-selected exercises the solutions of which are given at the end of the book.

HANS ZASSENHAUS, The Ohio State University

Introductory Numerical Analysis of Elliptic Boundary Value Problems. By Donald Greenspan. Harper and Row, New York, 1965. 164 pp. $7.00.

As the title implies this monograph introduces the reader to constructive solutions for elliptic problems. The opening chapter constitutes a dozen pages of prerequisite analytic concepts.

Through carefully prepared stages the author swiftly moves from an analysis of the standard two dimensional Laplace equation (Chapter 2) to multi-dimensional linear elliptic problems (Chapter 6). Along the way the reader is initiated to the mode of attack: a motivational development of appropriate difference equations followed by a convergence proof. (A ten page appendix analyzes some iterative methods for actually solving both linear and nonlinear systems.)

The final chapter (7) is titled Nonlinear Problems. By its very nature the material here quickly reaches research frontiers. Various open problems are presented. Chapter 7 in particular concludes with a carefully referenced detailed discussion of four "Research Problems."

Algorithms are clearly labeled (called "Methods"); theorems and lemmas on the whole are concisely stated, a rather unusual feat in numerical analysis; numerical examples are presented in a form which one can assimilate readily without becoming overwhelmed by a surplus of digits. Motivation is provided by associating the various differential equations with physical phenomena. The author continually teaches that problems need be well posed. There is an abundance of exercises and a very extensive bibliography.

It is unfortunate that the author chose to omit any analysis of rate of convergence or of error propagation—at either the discretization or iteration phases. Otherwise, this excellent text is admirably suited for use with either advanced undergraduates or beginning graduates. Though it will likely appeal primarily to mathematics majors, it should certainly be recommended for suitable serious students of the sciences. The price (about $4\frac{1}{4}$ cents per page) seems almost double what would be reasonable.

M. A. FELDSTEIN, Brown University

Einleitung in die Algebra und die Theorie der algebraische Gleichungen. By F. Nevanlinna. Birkhäuser Verlag, Basel and Stuttgart, 1965. 218 pages.

This book is intended as a clear, leisurely, well-motivated introduction to so-called "modern abstract algebra." The method chosen is a development of the machinery for a treatment of the theory of algebraic equations, both by the classical approach and by Galois theory. It is intended as a self-contained text for a short, introductory course (no number-theoretic or algebraic preparation necessary), or as a book for self-study, preparing the reader for "broader, more difficult" books, like van der Waerden's *Algebra*. The reviewer would rate it as an unqualified success in these aims, and something more.

The early chapters of the book give an excellent, fairly standard introduction to number theory, groups, integral domains and fields. There is more than enough here for the usual "first course in algebra" given to undergraduates in this country. (Quadratic reciprocity, perfect fields and Euclidean rings are even treated here.) These are followed by chapters on algebraic equations and algebraic field extensions. Here the theorem of the primitive element is proved, abelian extensions and ruler and compass constructions are discussed; then the equations of degree two, three and four are treated. Then, Abel's Theorem on the unsolvability by radicals of the general equation of degree n is proved by "classical" means. It is only after this that Galois theory is developed, in the last chapter, climaxing in a second proof of Abel's Theorem. The quality of exposition is very high throughout the book. The exercises (131 of them) are excellent, providing examples, drill, and extensive excursions. The paper and typography are good, and the reviewer was unable to find any errors—mathematical or typographical—in his reading of the book.

Were the language of the book English, this would be a top candidate for use in a first

course in algebra at almost any level. As it is, Professor Nevanlinna has provided a beautiful treatment of material which virtually no students in standard algebra courses get to see (the classical approach to Abel's Theorem), and there is enough material of interest throughout the book to recommend it to almost anyone who wants to read some algebra.

FREDERICK HOFFMAN, Institute for Defense Analyses, Princeton, N. J.

Commutative Normed Rings. By I. Gelfand, D. Raikov, and G. Shilov. Chelsea, Bronx, N. Y., 1964. 306 pp. $6.50.

The original (1960) and the German translation (1964) were reviewed in Math. Reviews 23, A 1242 and 29, 6327. Chapter VIII appeared as an appendix in the original, and Chapter IX is new. Neither appeared in the German translation. The material of Chapters V, VII, IX exists elsewhere only in the periodical literature. There is perpetuated (p. 83) what were once doubted and are now known to be false [E. Kallin, Proc. Nat. Acad. Sci., USA, 119 (1963), 821–824; MR 27, 2878]: the original statement and "proof" that a *locally* analytic function on a commutative normed ring is globally analytic. Section 13, where the error occurs, is now of principally historic interest and the closest relevant and valid material may be found in the following: R. Arens, Pacific J. Math. 11 (1961), 405–429; MR 25, 4373.

B. R. GELBAUM, University of California, Irvine

Algebraic Numbers. By Serge Lang. Addison-Wesley, Reading, Mass., 1964. xi+163 pp. $7.75.

This volume is a most welcome addition to the literature of the subject. The interplay of algebra and analysis, together with the author's lively style and erudition, combine to produce a book which should excite and stimulate its readers. Lang was a student of Artin, and we are fortunate to find in him an able expositor of the wonderful tradition in number theory associated with his teacher.

The first half of the book presupposes something like volume I of van der Waerden's algebra, the latter half, complex variables, elementary point set topology and a little distribution theory. The treatment strikes a balance between the global methods of earlier books such as Hecke's and the emphasis on the local theory to be found in some newer books such as that of Weiss. Beginning with a nicely arranged sketch of classical ideal theory in Dedekind domains, the author deals with algebraic integers, the different and discriminant, cyclotomic fields, parallelotopes, ideles and adeles, functional equation of ζ-functions, density of primes, the Brauer-Siegel theorem, and Weil's approach to explicit formulas.

BASIL GORDON, University of California at Los Angeles

Enumerability, Decidability, Computability. (Die Grundlehren der mathematischen Wissenschaften in Einzeldarstellungen, Vol. 127) by H. Hermes. Translated by G. T. Herman, and O. Plassman. Academic Press, New York, and Springer, Berlin, 1965. 245 pp. $9.75.

This is an introduction to the theory of recursive functions from a classical (non-intuitionistic) point of view. (Neither "Intuitionism" nor "Brouwer" nor "Heyting" appears in the index!). As in Martin Davis' book, *Computability and Unsolvability*, the framework is established by the discussion of Turing machines; μ-recursiveness also plays a large role. Applications of the theory include undecidability of the predicate calculus and incompleteness of arithmetic. The text is both unusually elementary and unusually clear. There are relatively easy problems at the end of every few paragraphs. For an undergraduate course in mathematics (Foundations . . .), or an undergraduate or graduate course in philosophy (Logic . . .), this competently written little book may be just the thing.

H. E. KYBURG, JR., University of Rochester

Notes on Logic. By Roger C. Lyndon. Van Nostrand, Princeton, N. J., 1966. vi+97 pp. $2.50.

This set of thirty-four lectures provides a compact and formal, yet surprisingly readable, introduction to mathematical logic. The treatment focuses attention on the important problems and goals of the subject, suppresses details of some philosophical interpretations, and ignores technical skills. There are no exercises.

The initial lectures treat, in addition to the program undertaken in logic, the grammar and semantics of sentential and predicate languages. The discussion of interpretations and structures is noteworthy. The important questions of decidability, axiomatizability, adequacy, and categoricity are raised and discussed in the context of the compactness and Skolem-Löwenheim theorems. Lyndon treats topics all too frequently excluded from a first course in logic: Gentzen's system of natural deduction in various formulations, proof of the Herbrand-Gentzen theorem, and Craig's theorem. The book ends with a concise but accurate discussion of the theorems of Tarski, Gödel, and Church on expressibility, incompleteness, and decidability, respectively.

The notes are worth the attention of any student of logic who has had an introductory course. They could serve as a difficult introduction to the subject for an exceptionally mature student.

D. L. KREIDER, Dartmouth College

Topological Vector Spaces. By Helmut H. Schaefer. Macmillan, New York, 1966. ix+294 pp. $10.95.

The book under review "is intended to be a systematic text" on topological vector spaces. For nearly a decade after the appearance in 1953 of Bourbaki's "Espaces Vectoriels Topologiques," no text-book on this topic appeared in English. The author's preliminary versions of the matter in this book were shaping up around 1958. In 1960, Köthe's "Topologische lineare Räume" appeared, and in 1963 Kelley, Namioka, *et al*, published what is perhaps the first English text-book on this topic. Schaefer's book preserves to a large extent the spirit of the Bourbaki texts, and includes also spectral properties of positive operators and a brief introduction to tensor products and nuclear spaces.

Brief summary of the contents: Chapter I: topological vector spaces and the related basic material such as metrization, completion and complexification. Chapter II: locally convex spaces. Chapter III: the space of linear mappings and the topologies on it. Chapter IV: fairly exhaustive account of the duality theory. Chapter V: ordered topological vector spaces. Each chapter is followed by numerous exercises which often supplement the text.

The book can be highly recommended for general reading and as a largely self-contained text-book.

M. S. RAMANUJAN, University of Michigan

Iterative Methods for the Solution of Equations. By J. F. Traub. Prentice-Hall, Englewood Cliffs, N. J., 1964. 18+310 pp. $12.95.

The author is concerned with the theory of iteration algorithms for the numerical determination of roots of equations and systems of equations. He is primarily concerned with the determination of a real root α of a real single-valued function $f(x)$ which has a certain number of continuous derivatives in the neighborhood of α. He assumes that the multiplicity of the root is an integer, that the root is isolated, and that a close approximation to the root is available. He is not concerned with the determination of initial values or with convergence criteria for the iteration algorithms. The theory is local, rather than global.

Four classes of iteration functions (IF) are considered: "one-point IF" (such as the Newton-Raphson method), "one-point IF with memory" (such as the secant method),

"multipoint IF" (similar to Runge-Kutta) and "multipoint IF with memory." Most of the IF are derived by the use of hyperosculatory interpolation, described in detail in Appendix A. Both inverse and direct interpolation are used.

The book is a scholarly piece of work with a considerable amount of new material and an extensive bibliography. It should become a basic reference for anyone desiring to do theoretical work in the field. On the other hand, it is not, and surely was not intended to be, a practical guide for writing a general-purpose computer program for automatically handling a large class of cases.

D. M. YOUNG, JR., University of Texas

Elements of the Theory of Nonlinear Oscillations. By N. V. Butenin. Blaisdell, Waltham, Mass. 1965. 226 pp. $7.50.

From the author's preface: "The author of this book has sought to give the reader at least an introduction to the theory of nonlinear vibrations, to acquaint him with a few of the methods of studying nonlinear systems, and to apply these methods to the solution of concrete problems." He succeeds, but at the cost of leaving the reader with the impression that the theory of nonlinear differential equations is quite primitive, and that the construction of approximations to the integral curves by graphical methods is still an important task. The publisher states that the book is "well suited for use as an advanced text in engineering schools." In my opinion, this claim should end with the phrase "in underdeveloped countries where the engineer will not have access to computers or the need of theory." On the other hand, the book contains many extremely interesting examples which are discussed in great detail, e.g., the dependence of the motion of a clock on its means of suspension (Kelvin's problem) and the self-excited oscillations of an autopilot.

The book is well designed and easy to read. In general, the translation (the book was first published in Leningrad in 1962) is careful, but stiff. There are the usual minor errors and omissions which can give pleasure to a reviewer but are otherwise unimportant. Once (page 188) after an "It is obvious that . . . " sentence, the editor felt obligated to insert a parenthetical remark "This is not entirely obvious; the reader should make certain that he understands the situation." I agree; it wasn't obvious.

W. T. KYNER, University of Southern California

Theoretical Numerical Analysis. By Burton Wendroff. Academic Press, New York, London, 1966. xi+239 pp. $10.95. (Telegr. Rev. page 340.)

This textbook is suitable for students at the graduate level. Occasionally some quite advanced concepts are introduced, but it is remarkable that the author does present proofs to some very deep theorems without requiring advanced mathematical knowledge. He follows what I consider the sound practice of selecting a limited number of algorithms in each area without attempting to be comprehensive. Many of the algorithms and proofs presented were until recently only available in the research literature. On the other hand the treatment of some areas is very sketchy (e.g., multistep methods and stability in the chapter on ordinary differential equations receive scant attention). Also the chapter on partial differential equations omits almost entirely the consideration of elliptic difference equations, but makes up for this by giving an excellent treatment of stability for initial value problems. Considering the size of the book the omission of some important topics was inevitable.

There seems to be developing in this country at least two types of numerical analysts: the mathematician type and the computer scientist type. This book is definitely intended for the former. The influence of the computer is somewhat superficial, occurring only in the selection of algorithms and in a few computer based exercises. There is little discussion of such computer science related aspects of algorithms as rates of convergence, round-off error propagation, storage problems, and computational efficiency.

S. D. CONTE, Purdue University

Estimation Theory. By Ralph Deutsch. Prentice-Hall, Englewood Cliffs, N. J., 1965. xiv+269 pp. $10.95. (Telegr. Rev., January 1967.)

Deutsch includes under the umbrella of *estimation theory* the ideas of least squares, polynomial approximation, smoothing and prediction of time series, as well as the topic usually called statistical estimation theory.

To understand these ideas one of course needs to know some mathematics and statistics. In writing a book of this sort, then, an author can either assume that his readers come prepared with the necessary background, or he can provide it for them. Deutsch has chosen the latter alternative, and has also included some historical notes on his subject, numerous exercises, and an extensive bibliography (!). This is an ambitious undertaking for a book of 269 pages. Nonetheless, I think Deutsch has largely succeeded in giving a good introductory account of the topic of estimation theory, as well as some of the mathematics, statistics, and numerical analysis necessary for the theory and for implementing the techniques.

The breadth of coverage and the brevity of the book dictate that the penetration into some topics is not too deep. Further, readers interested in mathematical rigor, i.e., careful attention to details in definitions and proofs, will have to look elsewhere. Similarly, readers seeking to implement techniques will find Deutsch's discussions helpful in getting an overview of the difficulties involved, but will have to seek particulars elsewhere. The extensive bibliography will help in these regards.

On balance, this is a worthwhile book. It could serve well as a course text provided the teacher is prepared to supplement, correct, and make the presentation rigorous.

E. M. SCHEUER, The RAND Corporation

NEWS AND NOTICES

EDITED BY RAOUL HAILPERN, SUNY at Buffalo

Readers are invited to contribute to the general interest of this department by sending news items to Raoul Hailpern, Mathematical Association of America, SUNY at Buffalo (University of Buffalo), Buffalo, New York 14214. Items must be submitted at least two months before publication can take place.

PERSONAL ITEMS

Professor R. C. James, Harvey Mudd College, represented the Association at the 75th Anniversary Convocation and Anniversary Conference of the California Institute of Technology from October 24 to October 27, 1966.

Mrs. Artha J. Snyder, Angelo State College, represented the Association at the inauguration of President G. E. Murray of Texas Technological College on November 1, 1966.

Professor W. L. Waltmann, Wartburg College, represented the Association at the inauguration of President P. F. Sharp of Drake University on October 28, 1966.

California Institute of Technology: Associate Professors R. A. Dean and F. B. Fuller have been promoted to Professors; Assistant Professor D. E. Knuth has been promoted to Associate Professor.

University of California at Santa Barbara: Dr. H. B. Keynes, Wesleyan University, has been appointed Assistant Professor; Assistant Professor D. A. Sprecher, Syracuse University, has been appointed Associate Professor; Dr. J. M. Zelmanowitz, University of Wisconsin, has been appointed Assistant Professor; Assistant Professor T. K. Boehme has been promoted to Associate Professor.

Cleveland State University: Associate Professor J. M. Egar, University of Akron, has been appointed Associate Professor; Assistant Professor R. L. Pruitt, Capital University, has been appointed Assistant Professor.

University of Connecticut: Dr. L. J. DeLuca, Syracuse University, has been appointed Assistant Professor; Associate Professor G. N. Raney has been promoted to Professor and has accepted the position of Acting Head of the Department of Mathematics.

Eastern Montana College: Mr. D. F. Furness, Church College of Hawaii, has been appointed Assistant Professor; Dr. W. A. Stannard, Montana State University, has been appointed Associate Professor.

Illinois Institute of Technology: Mr. Seymour Kass has been promoted to Assistant Professor; Associate Professor J. J. Mehlberg has been promoted to Professor.

Ithaca College: Mrs. Shirley O. Hockett, Cornell University, and Mr. Necdet Ucoluk, Clarkson College of Technology, have been appointed Assistant Professors.

Kansas State University: Dr. R. S. Sabharwal, Washington State College, has been appointed Assistant Professor; Assistant Professor F. B. Sloat has been promoted to Associate Professor.

Lock Haven State College: Mr. M. J. Brady, Waynesboro High School, and Mr. D. R. Wagner, Monclair High School, have been appointed Assistant Professors.

University of Maryland: Dr. J. J. Benedetto, The Institute for Fluid Dynamics and Applied Mathematics, Dr. P. J. Gowen, University of Virginia, and Dr. D. I. Schneider, Johns Hopkins University, have been appointed Assistant Professors; Associate Professor Carol R. Karp has been promoted to Professor.

Miami University: Dr. Syed Asadulla, University of Florida, Dr. R. M. Bullock, University of Cincinnati, and Dr. S. E. Payne, Florida State University, have been appointed Assistant Professors; Associate Professor S. E. Bohn has been promoted to Professor; Assistant Professors R. G. Laatsch and S. H. Tung have been promoted to Associate Professors.

Mississippi State University: Dr. W. M. Causey, University of Kansas, has been appointed Assistant Professor; Dr. F. Virginia Rohde, University of Chattanooga, has been appointed Professor; Assistant Professor C. T. Scarborough, Jr., Wayne State University, has been appointed Associate Professor.

University of New Hampshire: Associate Professor H. F. Bechtell, Bucknell University, has been appointed Associate Professor; Assistant Professors R. H. Balomenos, W. E. Bonnice, and D. M. Burton have been promoted to Associate Professors; Associate Professor E. H. Batho has been promoted to Professor.

University of New Mexico: Assistant Professor H. L. Bentley, Rensselaer Polytechnic Institute, has been appointed Assistant Professor; Professor G. M. Wing, University of Colorado, has been appointed Professor; Assistant Professor M. F. Janowitz has joined the faculty of Western Michigan University as an Associate Professor; Assistant Professors Heinz Renggli and Arthur Steger have been promoted to Associate Professors.

North Carolina State University: Dr. J. R. Kolb, University of Maryland, has been appointed Assistant Professor; Dr. J. A. Marlin has been promoted to Assistant Professor; Assistant Professor Kwangil Koh has been promoted to Associate Professor.

Professor W. A. Lafferty, Northwest Missouri State College, died on October 9, 1966. He was a member of the Association for twenty-seven years.

Professor H. P. Pettit, Marquette University, died in August, 1966. He was a member of the Association for forty-six years.

MATHEMATICAL ASSOCIATION OF AMERICA

Official Reports and Communications

APRIL MEETING OF THE MISSOURI SECTION

The spring meeting of the Missouri Section of the MAA was held at the University of Missouri at Rolla on April 30, 1966, Professor Charles Hatfield, Chairman of the Section, presiding. Sixty-four persons were present, of whom forty-six were members.

At the business meeting, the following officers were elected for 1966–1967: Chairman, Professor Dale Woods, Northeast Missouri State Teachers College; Vice-Chairman, Professor F. W. Wilke, University of St. Louis at St. Louis; Secretary-Treasurer, Professor E. C. Pringle, Northeast Missouri State Teachers College.

Professor John Andrews reported on the high school testing program and Professor Paul Burcham on the University of Missouri (Columbia) testing program for entering freshmen.

During the morning session, Professor Guido Weiss of Washington University, St. Louis, gave the main address on "The CUPM General Curriculum in Mathematics for Colleges."

A program of new films was scheduled for the afternoon session. The following papers were presented during the morning session:

1. *A projective method for linear equations*, by R. F. Keller, University of Missouri, Columbia

2. *Solution of a difference equation by means of a contour integral*, by Gary Walls, Northeast Missouri State Teachers College.

3. *Some vector families in E^3 with integral components, integral length and useful orthogonality properties*, by J. F. Gray, Society of Mary, Kirkwood.

4. *On arbitrary large postulate sets for the propositional calculus*, by John Bridges, Southwest Missouri State College, Springfield.

C. A. JOHNSON, *Secretary-Treasurer*

NOVEMBER MEETING OF THE INDIANA SECTION

On Saturday, November 5, 1966, the Indiana Section of the MAA met at Purdue University. Approximately 150 persons attended, including 62 members of the Association who registered.

The group was welcomed by Professor F. H. Haas, Dean of the School of Science, and the sessions were presided over by Professors G. R. MacLane and R. E. Zink.

At the business meeting, it was decided unanimously that the Section would recognize the top two competitors from Indiana on the Putnam Examination by awarding them a year's membership in the Association and announcing their achievement to the membership. Professor Paul Mielke reported on a team competition held among eight small colleges in the state last year and announced plans to repeat the undertaking this year in view of its success.

The program for the meeting was as follows:

1. *Blood flow and asymptotic uniqueness of a boundary value problem*, by H. M. Lieberstein, Indiana University.

2. *A reduction of Diophantine problems*, by A. Adler, Indiana University.

3. *Mathematics and space science*, by H. Pollard, Purdue University.

4. *Convergence of Fourier series*, by C. Goffman, Purdue University.

5. *An instability result for a linear differential-difference equation with constant coefficients*, by H. Bailey, Rose Polytechnic Institute.

6. *Ordinary differential equations in Banach space and functional equations of the retarded type*, by Z. Vorel, Rose Polytechnic Institute.

7. *Pointwise periodicity and Boolean algebras*, by F. B. Wright, Tulane University (Guest Speaker).

GEORGE PEDRICK, *Secretary*

NOVEMBER MEETING OF THE NORTHEASTERN SECTION

The twelfth annual meeting of the Northeastern Section of the MAA was held at Trinity College, Hartford, Connecticut, on November 26, 1966. The registered attendance was 151, including 131 members of the Association. Chairman Hartley Rogers, of the Massachusetts Institute of Technology, presided at the morning session and Vice-Chairman Robin Robinson, of Dartmouth College, presided at the afternoon session.

At the business meeting, the following officers were elected for the coming year: Chairman, Robin Robinson, Dartmouth College; Vice-Chairman, Guilford Spencer III, Williams College; Secretary-Treasurer, George Best, Phillips Academy.

The morning program was devoted to the following talks:

1. *Equivalences of differentiable structures*, by J. R. Munkres, Massachusetts Institute of Technology.

2. *Markov chains and potential theory*, by L. J. Snell, Dartmouth College.

Following the afternoon business meeting, the program continued with a panel discussion of *The CUPM report on the general curriculum in mathematics for colleges.* The panel was moderated by A. B. Willcox, Amherst College. Panelists were: V. O. McBrien, College of the Holy Cross; E. E. Moise, Harvard University; R. A. Rosenbaum, Wesleyan University; N. J. Schoonmaker, University of Vermont.

G. W. BEST, *Secretary-Treasurer*

NOVEMBER MEETING OF THE PHILADELPHIA SECTION

The forty-first annual meeting of the Philadelphia Section of the MAA was held at Villanova University, Villanova, Pennsylvania, on November 19, 1966. The Chairman, Professor Russell Remage Jr., University of Delaware, presided at the meeting. The meeting was attended by 172 persons including 137 members of the Association.

At the business meeting the following officers were elected: Chairman: Professor Emil Amelotti, Villanova University; Member of the Executive Committee, Professor R. J. Kohlmeyer, Albright College.

The following papers were presented:

1. *Some aspects of homological algebra-background and recent developments*, by J. C. Moore, Princeton University.

2. *Components of mathematical systems*, by P. C. Hammer, The Pennsylvania State University.

3. *A brief trip through the affine plane*, by Samuel Gulden, Lehigh University.

4. *The CUPM general curriculum in mathematics for colleges*, by D. W. Western, Franklin and Marshall College; J. A. Meier, Millersville State College; David Rosen, Swarthmore College.

5. Film: *Let us teach Guessing*, with George Polya.

V. V. LATSHAW, *Secretary-Treasurer*

CALENDAR OF FUTURE MEETINGS

Forty-eighth Summer Meeting, University of Toronto, Toronto, Ontario, Canada, August 28–30, 1967.

Fifty-first Annual Meeting, San Francisco, California, January 25–27, 1968.

The following is a list of the Sections of the Association with dates of future meetings so far as they have been reported to the Associate Secretary.

ALLEGHENY MOUNTAIN, West Virginia University, Morgantown, May 6, 1967.

ILLINOIS, University of Illinois, Urbana, May 12–13, 1967.

INDIANA, Wabash College, Crawfordsville, May 13, 1967.

IOWA, Drake University, Des Moines, April 21, 1967.

KANSAS, Fort Hays State College, Hays, April 22, 1967.

KENTUCKY, Murray State University, Murray, April 1, 1967.

LOUISIANA-MISSISSIPPI

MARYLAND-DISTRICT OF COLUMBIA-VIRGINIA, University of Virginia, Charlottesville, April 22, 1967.

METROPOLITAN NEW YORK

MICHIGAN

MINNESOTA, St. John's University, Collegeville, May 6, 1967.

MISSOURI, Northeast Missouri State Teachers College, Kirksville, April 29, 1967.

NEBRASKA, University of South Dakota, Vermillion, May 6, 1967.

NEW JERSEY

NORTHEASTERN, Mt. Allison University, Sackville, New Brunswick, June 23–24, 1967.

NORTHERN CALIFORNIA

OHIO, Ohio State University, Columbus, April 22, 1967.

OKLAHOMA-ARKANSAS

PACIFIC NORTHWEST, University of Montana, Missoula, June 16–17, 1967.

PHILADELPHIA, University of Delaware, Newark, Delaware, November 18, 1967.

ROCKY MOUNTAIN, Western State College of Colorado, Gunnison, May 12–13, 1967.

SOUTHEASTERN

SOUTHERN CALIFORNIA

SOUTHWESTERN

TEXAS, Austin College, Sherman, April 14–15, 1967.

UPPER NEW YORK STATE, State University College, Plattsburgh, May 20, 1967.

WISCONSIN, St. Norbert College, DePere, May 6, 1967.

FUTURE MEETINGS OF OTHER ORGANIZATIONS

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, New York, N. Y., December 26–31, 1967.

AMERICAN MATHEMATICAL SOCIETY, Toronto, Ontario, Canada, Aug. 29–Sept. 1, 1967.

AMERICAN SOCIETY FOR ENGINEERING EDUCATION, Michigan State University, June 19–23, 1967.

ASSOCIATION FOR COMPUTING MACHINERY, Sheraton-Park, Washington, D. C., August 29–31, 1967.

ASSOCIATION FOR SYMBOLIC LOGIC, Chicago, May 4–5, 1967.

CENTRAL ASSOCIATION OF SCIENCE AND MATHEMATICS TEACHERS, Chicago, November 23–25, 1967.

NATIONAL COUNCIL OF TEACHERS OF MATHEMATICS, Convention Center, Las Vegas, Nevada, April 18–21, 1967.

OPERATIONS RESEARCH SOCIETY OF AMERICA, New York Hilton Hotel, May 31–June 2, 1967.

PI MU EPSILON, Toronto, Ontario, Canada, August 29–30, 1967.

SOCIETY FOR INDUSTRIAL AND APPLIED MATHEMATICS, Shoreham Hotel, Washington, D. C., June 12–15, 1967 (Symposiums on applied probability and fluid dynamics).

two outstanding texts . . .

CALCULUS WITH ANALYTIC GEOMETRY

JOHN M. H. OLMSTED, *Southern Illinois University*

This modern basic text stresses clarity, precision, and thoroughness, instilling rigorous mathematical thinking while encouraging intuitive motivation. Following the historical development of integral calculus before differential calculus, the book also treats the global concept of uniform continuity before the local concepts of ordinary continuity and limits. Logical ideas used in mathematical analysis are introduced early, and quantifiers and negations of statements involving them are provided throughout. In two illustrated volumes. *Vol. I: 810 pp., $9.50; Vol. II: 655 pp., $7.00*

CALCULUS WITH ANALYTIC GEOMETRY

EDWIN J. PURCELL, *University of Arizona*

Rigorous enough to challenge the best student, yet lucid and interesting enough to stimulate the average student, this text features a thorough exposition of the formulas and techniques of calculus, and extensive coverage of vectors in two- and three-dimensional spaces. Set theory is introduced early and set notation is used where appropriate. All important definitions are prominently labeled, numbered, and displayed for easy reference. *843 pp., illus., $10.00*

NEW TEXTS

Calculus with Analytic Geometry and Linear Algebra

by Leopoldo V. Toralballa, *New York University*

This text, designed to be covered in two or three semesters at the freshman level, is a first course in calculus and analytic geometry, with an introduction to linear algebra. A two-level system of study is presented, with instructions for the use of the book on each level. The first level corresponds to an introductory course; the second level, an honors course.

CONTENTS: Basic Concepts of Set Theory. The Real Number System. Functions, Mappings and Graphs. The Derivative and the Integral. Introduction to the Applications of the Integral. The Derivative: Introduction to the Applications of the Derivative. Plane Analytic Geometry. Elementary Functions. Applications of the Derivative. The Search for the Primitives: Applications of the Integral. Further Applications of the Integral. Infinite Series of Constants. Infinite Series of Functions: Power Series. Linear Algebra. The Euclidean Vector Spaces. Analytic Geometry of E^3. Functions of Two or More Real Variables. Multiple Integrals. Applications of the Multiple Integral.

1967, 920 pp., $11.95

Computer Programming and Computer Systems

by Anthony Hassitt, *University of California, San Diego*

1967, 374 pp., $10.75

Abstract Algebra

by Chih-Han Sah, *University of Pennsylvania*

A one-year course at the advanced-undergraduate or beginning-graduate level. Exercises form an integral part of the text, with detailed references at the end of each chapter.

CONTENTS: Natural Numbers, Integers, and Rational Numbers. Groups, Rings, Integral Domains, Fields. Elementary Theory of Groups. Elementary Theory of Rings. Modules and Associated Algebras Over Commutative Rings. Vector Spaces. Elementary Theory of Fields. Galois Theory. Real and Complex Numbers.

1967, 342 pp., $9.75

Elementary Topology

A COMBINATORIAL AND ALGEBRAIC APPROACH

by Donald W. Blackett, *Boston University*

Designed for a one semester undergraduate course in one, two and three dimensional topology, emphasizing combinatorial and algebraic methods. Topics such as classification of surfaces, covering surfaces, fixed point theorems, vector fields, networks and simple three-manifolds keep the focus of the book on concrete examples.

1967, 224 pp., $9.50

Introduction to Ordinary Differential Equations

by Albert L. Rabenstein, *Macalester College*

"This text is especially well written and thorough. The topics are presented clearly and precisely. The problems are interesting and appear to challenge the student." R.L.B., *Butler University*

REPRESENTATIVE ADOPTIONS: University of Colorado, Auburn University, Pennsylvania State University, State University of Iowa, Macalester College, United States Air Force Academy, Idaho State University.

1967 MATHEMATICS TEXTS FROM PRENTICE-HALL

INTRODUCTION TO CONTEMPORARY ALGEBRA, by Marvin L. Tomber, Michigan State University.
Based on the structure of algebra, Dr. Tomber's underlying theme is the rational development of algebra as a fundamental human discipline. An informal development of algebra from its axioms, this book has been prepared to meet the requirements of modern algebra courses as outlined by the Committee of the Undergraduate Program in Mathematics. January 1967, 428 pp., $7.95

MAXIMUM PRINCIPLES IN DIFFERENTIAL EQUATIONS, by Murray Protter, University of California, Berkeley, and Hans Weinberger, University of Minnesota, Minneapolis.
An elementary account of maximum principles for ordinary differential equations as well as elliptic, parabolic, and hyperbolic second order partial differential equations. The authors stress applications to the numerical approximation of solutions and to error bounds in the application. September 1967, approx. 256 pp., $8.00

THE STRUCTURE OF THE REAL NUMBER SYSTEM: A Programmed Introduction, by John D. Baum, Oberlin College, and Roy A. Dobyns, McNeese State College.
A self-instructional, programmed book on real number systems which follows the recommendations of the C.U.P.M. Panel of teacher training. The authors' presentation is first descriptive and then axiomatic. Containing more than a simple development of the real number systems, the book includes introductory material on set theory, truth sets, inequalities, coordinate systems, and functions. A teacher's manual is available. April 1967, approx. 288 pp., $6.95

INTEGRATED ALGEBRA AND TRIGONOMETRY: With Analytic Geometry, 2nd Edition, 1967, by Robert C. Fisher, The Ohio State University, and Allen D. Ziebur, State University of New York at Binghamton.
A thorough revision of one of the most successful pre-calculus mathematics texts published. (Over 158,000 copies sold of previous edition.) The unifying theme of the book is the concept of the function and its graph. New to this edition are the introduction of the language and notation of sets, and the treatment of analytic geometry. Color illustrations have been incorporated into the text. March 1967, approx. 448 pp., $8.95

INTRODUCTORY COMPLEX ANALYSIS, by Richard A. Silverman, formerly of the Courant Institute of Mathematical Sciences of New York.
A basic college senior or first year graduate course in Complex Variable Theory and its applications. This completely self-contained text requires a background in advanced calculus. Presents a thorough treatment of elementary functions, polynomials and rational functions, with separate chapters on harmonic functions. January 1967, 372 pp., $8.50

LINEAR TRANSFORMATIONS AND MATRICES, by F. A. Ficken, New York University.
A new text presenting the basic theory of finite-dimensional real and complex linear spaces. For students taking a first "conceptual" course. The material was class-tested by the author for over two years before final publication. January 1967, 398 pp., $10.50

APPLIED DIFFERENTIAL EQUATIONS, 2nd EDITION, 1967 by Murray R. Spiegel, Rensselaer Polytechnic Institute.
This revised and updated 2nd Edition maintains the objectives of the highly successful first edition. It briefly and clearly provides an elementary, reasonable understanding of differential equations for students of engineering, physics, chemistry and mathematics. This new edition features: a chapter on Laplace transform methods; an enlarged chapter on the Numerical Solution of Differential Equations by the addition of a section on the Runge-Kutta method and others. February 1967, 384 pp., $8.50

Introduction to ALGOL Programming

By TORGIL EKMAN *and* CARL-ERIK FRÖBERG

This modern textbook in ALGOL, the programming language of international status, is useful for applications with a background of mathematics and natural sciences and for applications within the field of administrative data processing. Solutions and answers to exercises; bibliography.

1966 123 pp. $5.00

Numerical Solution of Partial Differential Equations

By G. D. SMITH, *Brunel College of Advanced Technology, London*

Designed as a textbook for students with no previous knowledge of numerical methods, this volume is also intended as a bridge to the increasing number of advanced treatises on the numerical solution of partial differential equations. Exercises and worked solutions are included.

1965 190 pp. $5.00

An Introduction to Numerical Linear Algebra

With Exercises

By L. FOX, *Oxford University*

This introduction covers the practice of matrix algebra and manipulation, and the theory and practice of direct and iterative methods for solving simultaneous linear algebraic equations, inverting matrices, and determining the latent roots and vectors of matrices.

FOUNDATIONS IN MODERN MATHEMATICS

W. GRAHAM MAY, *Wake Forest College*

This first-year, one-semester book emphasizes the algebraic structure number system and the properties of elementary functions. The concepts of set, relation, and function are investigated, and topics in algebra and trigonometry are presented to build a solid foundation for future courses.

1967. 336 pages. $7.50

BASIC SKILLS IN MATHEMATICS

JOHN N. FUJII, *Merritt College*

This freshman level text reviews and strengthens the basic arithmetic skills through simple explanations, examples, and many sets of practical problem exercises. Careful attention has been paid to keep the vocabulary required in using this book as simple as possible.

In press

CALCULUS, Volume I: One-variable calculus with an introduction to linear algebra.

TOM M. APOSTOL, *California Institute of Technology*

The second edition has been divided into smaller chapters, each centering on an important concept. Proofs now follow immediately after discussion of the theorems. The last third of Volume I provides a natural blending of algebra and analysis and helps pave the way for the transition from one-variable calculus to multi-variable calculus discussed in Volume II.

In press

FIRST ORDER MATHEMATICAL LOGIC

ANGELO MARGARIS, *Ohio State University*

Written for advanced undergraduate and beginning graduate students who have had little or no acquaintance with abstract mathematics, this text concentrates on first-order logic, presupposing no particular mathematical background. It includes illustrative examples, detailed proof of theorems, and numerous exercises.

In press

1966

INTRODUCTION TO ALGEBRA

SAM PERLIS, *Purdue University*

This text, designed for an introductory course in modern algebra or separate courses in linear and abstract algebra, presents the concepts and elementary facts of five systems: groups, rings, integral domains, fields, and vector spaces.

1966. 440 pages. $9.50

INTRODUCTION TO NUMERICAL ANALYSIS

GERARD P. WEEG, and GEORGIA B. REED, *University of Iowa*

This text is for use in intermediate college one-term courses. The prerequisites are calculus and an introduction to differential equations. Some training in FORTRAN should be given with parallel use of this book.

CALCULUS AND ANALYTIC GEOMETRY, Second Ed.

ABRAHAM SCHWARTZ, The City College of the City University of New York

As in the first edition, this text for the introductory calculus course begins with chapters on the differential and integral calculus which rest on an intuitive basis rather than an abstract one. In the second edition, the definition of "function" at the beginning of the book has been rewritten in more precise terms, and the first intuitive definition for integrals in Chapter Two has been improved. A completely new feature is the addition of a chapter on differential equations. This chapter places more emphasis than usual, at this level, on uniqueness theorems. It also treats physical application, especially for linear equations with constant coefficients.

March 1967 **1024 pp.** **$12.50**

INTRODUCTION TO NUMBER THEORY

JAMES E. SHOCKLEY, Virginia Polytechnic Institute

Designed for a one semester course in number theory, this text offers a good deal of exposition in its treatment of the subject. While maintaining rigor, proofs are treated in a more gradual style than the usual terse manner of presentation. Most of the chapters are virtually independent of each other and can be treated in any sequence. Other features include a liberal interjection of historical summaries and brief surveys of more advanced results which may be assigned for outside reading.

February 1967 **256 pp.** **$7.95**

A SURVEY OF COLLEGE MATHEMATICS

DONALD R. HORNER, Eastern Washington State College

Here is an introduction to mathematics that offers, at an elementary level, both an appreciation of mathematical abstractions and a broad survey of the main topics in mathematics. Some of the concepts of pure mathematics are developed in the first chapters where logic, set theory and basic number systems are introduced. Chapter Four provides a review of high school algebra while the remaining chapters present a broad treatment of matrices and determinants, probability and statistics, analytic geometry, trigonometry, and elementary calculus. Each topic is entered into as a result of the needs of other disciplines, such as business administration, biology, psychology, and education.

Physical Scientist? **Engineer?**

You all have one thing in common— MATHEMATICS

CALCULUS

An Intuitive and Physical Approach—*In two parts*

by **MORRIS KLINE,** *The Courant Institute of Mathematical Sciences, New York University.*

Consistently intuitive—in the justification of the theorems and techniques . . . in the use of geometrical, physical, and heuristic arguments and generalization from concrete cases . . . in the emphasis on discovery in mathematics

Strong on applications—real problems motivate and introduce the mathematics . . . genuine physical problems employ the mathematics that have been developed . . . applications introduced early in each development provide concrete step-by-step understanding

Easy to follow—Scientific ideas are carefully explained when they are utilized . . . clarity and informality characterize the style of writing . . . detailed developments with emphasis on calculus concepts rather than algebra provide a firm basis for understanding

Easy to teach—the Teacher's Manual contains complete solutions of all problems—with particular emphasis on details for handling the physical problems.

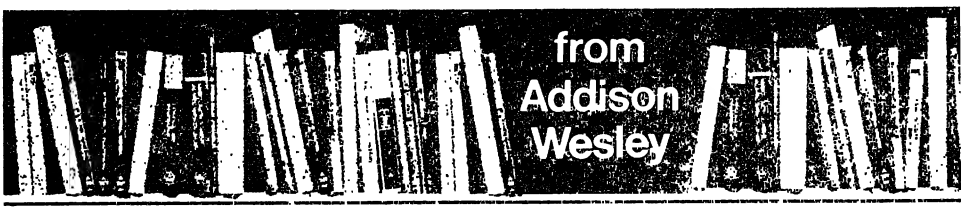
Part I covers the differential and integral calculus of one variable and analytic geometry.

1967. 574 pages. $9.95.

Part II develops the calculus of several variables and provides an introduction to rigorous calculus.

1967. Approx. 448 pages. $8.75.

Mathematics and Computing with FORTRAN Programming



By WILLIAM S. DORN, *Thomas J. Watson Research Center, IBM; and* HERBERT J. GREENBERG, *University of Denver.* This is a mathematics text which requires the student to use a computer and FORTRAN programming to increase and enhance his understanding of the mathematics. Linear algebra, logic, probability and intuitive calculus are covered. An instructor's edition contains marginal notes and solutions to all the problems. The instructor needs no prior training in programming. *1967. Approx. 640 pages. Prob. $8.95.*

Mathematical Logic

By STEPHEN COLE KLEENE, *The Institute for Advanced Study, Princeton, New Jersey.* NOW AVAILABLE—a mathematical logic book for advanced undergraduates—by the author of the well-known *Introduction to Metamathematics.* Begins with a thorough but elementary exposition of propositional and first order predicate calculi, including equality, which permits the reader to work with logic from the beginning. Methods and applications to the foundations of mathematics are then discussed. The natural approach to Gödels completeness theorem and the new theorems of Craig, Beth and Robinson are explained. Exercises are provided. *1967. Approx. 416 pages. Prob. $10.50.*

MODERN COLLEGE ALGEBRA

SECOND EDITION

by

ELBRIDGE P. VANCE

Oberlin College

When the first edition of this highly successful college algebra text was being written, the influence of CUPM, SMSG, and the Commission on Mathematics of the College Entrance Examination Board upon mathematics at this level was already seriously felt. Since that time, certain other suggestions have been made by various influential groups. It is because of the changing mathematical world, and the suggested introduction of additional new topics that a new edition of this book seemed appropriate.

Special Features of Second Edition . . .

1. This edition has included new material on matrices, and a new approach to vectors, both strongly recommended at this level and both perfect preparation for later courses in linear algebra.
2. Several references are made to computing machines and methods used in this field.
3. The problems in this new edition have been augmented. Also, there are four new sets of review problems included at appropriate places.
4. Some problems emphasize the important ability to manipulate, while others deal with more theoretical ideas.

This text for a first course not only covers the essentials of algebra, but also attempts to instill in the student an appreciation of algebra as a logical subject. The importance of developing computational skill, as a basis for future courses, is not overlooked. To this end adequate time is devoted to manipulative work, without diminishing the student's interest, and ample problems are provided.

Perhaps the most unusual feature of the book is the author's use of the postulational approach. Although not emphasized, the notion of sets is introduced at the beginning and used throughout. The order axioms, along with a detailed discussion of inequalities, are presented. Enough use is made of coordinate systems to lend more significance to the study of equations. The concepts of function and relation are introduced early, and are an integral part of the exposition throughout the remainder of the book.

TABLE OF CONTENTS

Sets and Numbers
The Algebra of Numbers as a Logical System
Extensions of the Logic of Algebra
Inequalities, Absolute Values, and Coordinate Systems
Functions and Their Graphical Representation
Linear and Quadratic Functions
Determinants
Polynomial Functions
Inverse Functions
Permutations, Combinations, and the Binomial Theorem
Mathematical Induction
Exponential and Logarithmic Functions
Algebra of Ordered Pairs *In Press.*

THE SIGN OF EXCELLENCE

A Harper & Row Selection

New Publications

INTRODUCTION TO LINEAR ALGEBRA
Peter J. Kahn

Emphasis is on the development of mathematical insight and problem-solving capacity as the book proceeds from the specific to the general, the concrete to the abstract, the geometric to the algebraic. **446 pages; $11.95**

INTERMEDIATE ALGEBRA FOR COLLEGE STUDENTS, Third Edition
Thurman S. Peterson

The author presents the fundamentals of mathematics in a problem-solving approach, developing the logical structure of sets and the axiomatic structure of the real number system. Review sets have been reduced; most of the problems are revised. Answers to odd-numbered problems are provided in the text; answers to even-numbered problems and complete solutions to special problems for better students are available separately to the instructors. **378 pages; $7.50**

ANALYTICAL TRIGONOMETRY
Thomas J. Robinson

"An excellent text. The development and analysis of the the trigonometric functions, as functions, is masterful. This development is sure to further a student's understanding of the function concept and its study will serve as excellent preparation for calculus. In addition, Mr. Robinson has done what few authors of 'modern' trigonometry texts have done: he has included a well-written, well-organized, and reasonably comprehensive chapter dealing with triangle applications." **Donald Conway, Martin Dreyfus, Florence Lovaglia, San Jose City College. 182 pages; $6.00**

THEORY OF ARITHMETIC—Second Edition

By JOHN A. PETERSON, *University of Montana;* and JOSEPH HASHISAKI, *Western Washington State College.* Inspired by the warmth and enthusiasm with which the first edition was received (now in use at over 260 colleges and universities and universally adopted for in-service programs for elementary teachers), and assisted by the many helpful suggestions of its users, Peterson and Hashisaki have written a second edition of *Theory of Arithmetic.*

Precise definitions and simple but accurate presentations of fundamental ideas make the sophisticated concepts of modern mathematics accessible to the practicing and prospective elementary school teacher. The language of sets and the concept of relations are developed first and then used as a basis for teaching both the algebraic and order properties of the systems of whole numbers, integers, rationals and reals. The latter portion of the book is devoted to geometry. An *Instructor's Manual* will be available.
1967 337 pages. Prob. $7.50.

Pre-Calculus Mathematics: A Programmed Text

I. Algebra
II. *Functions and Relations*
III. *Analytic Trigonometry*

By VERNON E. HOWES, *University of Maryland.* An auto-instructional text in three volumes, designed for students who are not prepared for college calculus. Understanding is gained through problem solving, rather than repetition of material. The instructor's manual contains teaching suggestions, tests, and forty problem sets with answers. *In press. $4.95 per volume.*

ADVANCED ENGINEERING MATHEMATICS— Second Revised Edition

By ERWIN KREYSZIG, *The Ohio State University.* Careful selection of the most frequently applicable topics—many (over 3500) well-chosen problems—balance between theory and application —and provision for the varying backgrounds, abilities, and goals of the students—made the first edition of "Kreyszig" a best-seller.

Now there's a new edition. It has a new chapter on "Probability and Engineering Statistics", (which can be used independently, if desired) and more problems than ever (80% of them new in this edition). Much of the material has been rewritten for increased clarity and simplicity; and the organization of the chapter on "Complex Analysis" has been greatly improved. Numerical analysis is now introduced in the chapters on "Differential Equations" and "Fourier Analysis". An answer book will be available. *1967. Approx. 984 pages. Prob. $11.95.*

Informal Geometry

By LAWRENCE A. RINGENBERG, *Eastern Illinois University.* Informal approach—modern vocabulary and notation—rapid pace—in an elementary text designed for liberal arts and mathematics education students. Most of the theorems are motivated using experience with physical objects or illustrations, and most are stated without proof. The point set approach is used throughout. PROPOSED CONTENTS: Congruence and Similarity. Parallel Lines. Area. The Elements of Solid Geometry. Surfaces and Solids. Incidence Geometry. Distance and the Ruler Postulate. Convexity and Separation. Angles. Polygons. Constructions with Euclidean Ruler and Compasses. *1967. Approx. 192 pages. Prob. $4.95.*

605 Third Avenue, **New York, N.Y. 10016**

THE SLAUGHT MEMORIAL PAPERS

REDUCED PRICE FOR ORDERS OF FIVE OR MORE COPIES

The Herbert Ellsworth Slaught Memorial Papers are a series of brief expository pamphlets (paper bound) published as supplements to the American Mathematical Monthly.

The regular price is $1.50 per copy. For orders of five or more (any assortment) the price is reduced to $1.00 per copy.

The following numbers have been published recently:

3. *Proceedings of the Symposium on Special Topics in Applied Mathematics.* Nine articles by various authors. iv + 73 pages

4. *Contributions to Geometry.* Eight articles by various authors. iv + 75 pages

5. *The Conjugate Coordinate System for Plane Euclidean Geometry,* by W. B. Carver. vi + 86 pages

6. *To Lester R. Ford on His Seventieth Birthday.* A collection of fourteen articles. vi + 106 pages

7. *Introduction to Arithmetic Factorization and Congruences from the Standpoint of Abstract Algebra,* by H. S. Vandiver and Milo W. Weaver. iv + 53 pages

8. *Elementary Point Set Topology,* by R. H. Bing. iv + 58 pages (1966 reprint)

9. *A Contemporary Approach to Classical Geometry,* by Walter Prenowitz. vi + 67 pages

10. *Computers and Computing.* Twenty-one articles by R. W. Hamming, D. H. Lehmer, et al. ii + 156 pages

11. *Papers in Analysis.* Twenty-three articles by Kac, Piranian, Berberian, Hildebrandt, et al. iv + 157 pages

McGraw-Hill announces covering instructor/student

CALCULUS IN THE FIRST THREE DIMENSIONS.
By SHERMAN R. STEIN, University of California, Davis.

This introductory calculus text for a one-year course stresses the fundamentals and offers a broad range of applications. The book is divided into three parts: Part I deals with such topics as the definite integral, the derivative and the law of the mean. Part II covers special topics such as higher derivatives, maxima, series and vectors. Part III contains applications of calculus in such fields as economics, the physical sciences, and psychology. In a new approach to rigor, the book uses more counter-examples and less epsilon-delta terminology in dealing with the fine points of calculus. **640 pp., $9.95**

FIRST STEPS IN PROBABILITY.
By MEYER DWASS, University of North Carolina.

This elementary treatment of basic mathematical probability theory presents important concepts without bogging down in combinatoric manipulations. It emphasizes basic concepts such as sample space and probability measure, random variable, expected value, conditional frequency distributions, independence, correlation and regression, elements of simple random walk, special distributions, etc. **Off press**

ANALYTIC GEOMETRY: A Programmed Text.
By THOMAS A. DAVIS, DePauw University.

This self-instructional, programmed text enables each student to spend the time he needs on each topic. It is comprised of two units—The Line and The Conics—and uses a modified linear style in working straight through the program. It deals first with the information and ideas necessary for working with the equations of straight line; then with the circle, hyperbola, parabola, and ellipse. **Spring**

BASIC CONCEPTS OF MATHEMATICS.
By CHARLES G. MOORE and CHARLES E. LITTLE, both of Northern Arizona University.

Not a calculus text, this book is designed as a text for a one- or two-semester survey of mathematics. It is written for liberal arts or education majors taking their final mathematics course. The book acquaints these students with the point of view of the mathematician and the contributions of mathematics to our culture. **Spring**

A PRELUDE TO THE CALCULUS.
By MALCOLM W. POWNALL, Colgate University.

Three fundamental topics—*the real number system, functions,* and *limits*—are presented in such a way that a careful calculus course can be built upon the text. The book is designed to develop an understanding of concepts and theory, and particular attention is given to the clarity of the definitions and theorems, abundant examples, and variety of problems. Terminology and notation are consistent with most calculus texts. **Spring**

A SHORT COURSE IN DIFFERENTIAL EQUATIONS.
By W. R. UTZ, University of Missouri.

This concise text has been written for students who do not plan to take a full-length course in differential equations. It contains all the topics of a full elementary differential equations course, but no applications. The book features a chapter on matrix methods for solving differential equations, beginning with a review of vectors and matrices, which can be studied without prior experience with matrices. **Spring**

NUMBER SYSTEMS: An Elementary Approach.
By J. RICHARD BYRNE, Portland State College.

This new introductory text is a one-semester version of the author's very successful *Modern Elementary Mathematics.* It presents a modern treatment of the number system of elementary mathematics for college students. Special attention is devoted to the needs of students preparing to teach in elementary schools. Abundant examples illustrate and motivate mathematical ideas, and full exercise sections are included. **Off press**

these important new books needs up through calculus

ELEMENTARY MATHEMATICS: A Modern Aproach.

By JACK D. WILSON,
San Francisco State College.

This text is designed for introductory courses where students are preparing for careers in elementary education. It is organized to present instruction in both conventional and modern mathematics, and its contents follow the recommendations of the CUPM. The presentation is systematic, starting with set theory, culminating with the system of real numbers, and including important traditional topics. **Off press**

FUNDAMENTALS OF COLLEGE ALGEBRA.

By CARL B. ALLENDOERFER,
University of Washington; and
CLETUS O. OAKLEY, Haverford College

This modern treatment for the regular course offers much more than just "college algebra": it includes sets and logic; an unusually careful discussion of mathematical induction; introduction to matrix and vector algebra; stress on solution of inequalities in one and two variables; and unusually large sets of problems. Illustrations, marginal notes and important text statements in color speed and enhance the student's comprehension.
446 pp., $7.50

LIMITS AND CONTINUITY.

By TEDDY C. J. LEAVITT,
State University College, Plattsburgh, N.Y.

This helpful supplement leads students from intuitive ideas about the difficult concepts of limits and continuity to the fairly rigorous definitions and manipulations that are a part of the calculus course. Algebra, topology, and modern analysis are combined in a new way to simplify the concept of continuity and limits. Program material is so constructed as to allow the student to discover his own proofs and develop the mathematical rigor for himself. **Spring**

COLLEGE ALGEBRA, 5th Edition.

By PAUL K. REES, Louisiana State University; and FRED W. SPARKS, Professor Emeritus, Texas Technological College.

The new edition of this highly teachable text features axiomatic rigor using modern terminology and the theory of sets, rather than the traditional, relatively looser approach. It presents the essentials for further progress in clear, concise style. Graded problems are provided a normal lesson apart, with the degree of difficulty increasing gradually through the exercise. **Off press**

ALGEBRA, TRIGONOMETRY AND ANALYTIC GEOMETRY.

By PAUL K. REES, Louisiana State University; and FRED W. SPARKS, Professor Emeritus, Texas Technological College.

Again in this introductory text, the authors present the basic concepts of algebra, trigonometry and analytic geometry for the successful study of calculus. The first 26 chapters are from the authors' *Trigonometry (McGraw-Hill, 1962)* and the remainder presents the geometry background for a course in analytic geometry or calculus. 82 exercise sets, with some 2800 problems, arranged according to difficulty, supplement the main text.
496 pp., $8.50

FUNDAMENTAL MATHEMATICS, 3rd Edition.

By THOMAS L. WADE and HOWARD E. TAYLOR, both of Florida State University.

In the third edition of this well-established introductory college mathematics text, the topics proceed from a basis in sets and are discussed in modern terminology. The book is thoroughly revised; it increases emphasis on structure or pattern in fundamental mathematics and makes more use of the concepts of set, set operations, and set symbolism.

CALCULUS: Complete
CALCULUS: Part I ■ CALCULUS: Part II

By Edwin E. Moise, *Harvard University*

WHAT USERS ARE SAYING ABOUT THIS TEXT—
"A most challenging and refreshing approach. This should make calculus live for the student."

"It is an outstanding book in every respect, with clear explanations, as well as rigorous proof of all theory. Excellent problem sets develop the theory fully."

"First class. Makes other books seem old-fashioned."

"Excellent. Just what you expect of Professor Moise. I like his motivation, spiral approach, and selection of problems."

"A distinct step forward in introductory calculus books."

"The classroom experience of the author is obvious on every page. An excellent intuition—motivated treatment followed by the degree of rigor appropriate to the situation."

This text is intended for an introductory calculus and analytic geometry course of three or four terms, and assumes only eleventh grade high school algebra.

All ideas are introduced intuitively before being formalized, and the book is theoretically thorough in the sense that every topic is eventually treated logically and exactly.

Part I treats exponentials, logarithms, and trigonometric functions, and assumes some prior knowledge of these subjects. Ideas such as that of a coordinate system in a plane, and mathematical induction are explained from the beginning. There is a steady rise in the maturity level at which ideas are presented with various abstract ideas being discussed at times when they are needed.

Part II treats the calculus of several variables. Among the topics covered are infinite series, strongly emphasizing term-wise integration and differentiation and the differential equations which characterize the elementary functions of classical analysis.

Discussions of linear algebra and solid analytic geometry with vectors are also included. Multiple integrals are stressed as the natural formulation of geometric and physical ideas, and the material on differential equations mainly emphasizes the real domain.

SPECIAL FEATURES:

- The spiral process is used throughout with the more difficult ideas being presented in a series of different forms, in ascending order of difficulty, generality, and exactitude.
- The text is available in either two volumes or in a single edition.
- Stress is placed on careful motivation of the ideas in terms of concrete interpretations.
- Three chapters of linear algebra as well as topics in differential equations are included in Part II.

New and Recent Books from Macmillan:

MATHEMATICS FOR ELEMENTARY SCHOOL TEACHERS

By Helen L. Garstens, and Stanley B. Jackson, both, The University of Maryland

Written for the practicing and prospective elementary school teacher, this textbook presents a sound exposition of the basic concepts of elementary school mathematics—number and measure. A Teacher's Manual is available.
1967, approx. 512 pages, $9.95

MODERN CALCULUS WITH ANALYTIC GEOMETRY, Volume I

By A. W. Goodman, University of South Florida

This is the first book in a two volume set. It presents a rigorous approach to single variable calculus, suitable for use by students in mathematics, science, and engineering.
1967, approx. 832 pages, prob. $10.95

INFINITE SERIES

By Earl D. Rainville, late Professor of Mathematics, The University of Michigan

Distinguished for the clarity of his exposition and style of writing, Professor Rainville presents in this text a basic introduction to infinite series. Detailed explanations, many illustrative examples and more than 500 problems are provided.
1967, 265 pages, $7.95

FIRST-YEAR CALCULUS

By Arthur B. Simon, Northwestern University

This text provides a rigorous and lively introduction to the study of single variable calculus, including infinite series and vectors. The text successfully blends three elements to make it especially teachable: drill, counter-balanced by rigor and tempered by intuition.
1967, approx. 400 pages, $9.95

AN INTRODUCTION TO ANALYSIS

By Wilson M. Zaring, University of Illinois

The author takes a structural point of view in this text, emphasizing the role of the field postulates and includes a number of proofs and theorems that do not appear in other books at this level. Tested for several years prior to publication in NSF-sponsored institute courses.
1967, approx. 352 pages, prob. $8.95

A SURVEY OF MODERN ALGEBRA, Third Edition

By Garrett Birkhoff, Harvard University, and Saunders Mac Lane, The University of Chicago

". . . still probably the best introduction to the subject because it never loses sight of the concrete origins of the abstract ideas or of their applications in other fields, and is clearly written with many examples and exercises."

Science Books, May, 1966

1965, 437 pages, $8.50

INTRODUCTION TO LINEAR ALGEBRA

By Marvin Marcus, and Henryk Minc, both, The University of California, Santa Barbara

This text is an elementary but rigorous introduction to the fundamental concepts of linear algebra and matrix theory. Intended for sophomore-junior students, it provides simultaneous coverage of matrix and linear transformation approaches.
1965, 225 pages, $7.95

ELEMENTARY DIFFERENTIAL EQUATIONS, Third Edition

By Earl D. Rainville, late Professor of Mathematics, The University of Michigan

This edition of a widely used text, greatly revised and rewritten, continues to offer the student an understanding of elementary differential equations as well as sound techniques for solving them. More than 1800 exercises.
1964, 521 pages, $7.75

EDITORIAL CORRESPONDENCE AND MANUSCRIPTS OF PAPERS should be addressed to the Editor, R. A. Rosenbaum, Wesleyan University, Middletown, Conn. 06457.

ADVERTISING CORRESPONDENCE should be addressed to RAOUL HAILPERN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

NOTICE OF CHANGE OF ADDRESS by members of the Association as well as correspondence regarding subscriptions to the MONTHLY should be sent to the Executive Director, H. M. GEHMAN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

NOTICE TO AUTHORS

The MONTHLY welcomes papers presenting valid mathematics, of rather general interest, at a level intelligible to persons with two years of full-time graduate study. Some novelty of content, viewpoint, or arrangement is essential. Expository articles are particularly desired. State the context and the principal aim of the paper early. Address yourself quite explicitly to the reader described above, communicating your ideas to him clearly and attractively.

The title should be brief and meaningful. Since the title will be quoted and reproduced by laymen, it should contain no symbols unfamiliar to laymen.

Articles should be typewritten, double-spaced, on $8\frac{1}{2}\times 11''$ paper of very good quality. Submit the original (and a duplicate if convenient) keeping a complete copy for yourself. To avoid loss and delay notify us of any change of address.

The typescript should be prepared with extreme care. Misprints are highly obnoxious; so are dangling participles. Put name and address between title and text. Put references at the end with bracketed citations in the text. Avoid footnotes; instead, use clearly designated remarks in the text. Put acknowledgments at the very end, just before the bibliography. Be generous with spacing and displays. *Keep notation simple.* For a matrix the notation $[a_{jk}]$ is recommended, with det $[a_{jk}]$ or $[a_{jk}]$ for the determinant. On doubtful questions regarding format or notation, observe practices in current issues of the MONTHLY or consult the applicable sections of the "Author's Manual" of the American Mathematical Society.

Annual dues for members of the Association (including a subscription to the American Mathematical Monthly) are $6.00. For nonmembers the subscription price is $10.00.

PUBLISHED BY THE ASSOCIATION at Menasha, Wisconsin, and Buffalo, N. Y.
during the months of January, February, March, April, May, June–July, August–September, October, November, December.

Second-class postage paid at Menasha, Wisconsin. Acceptance for mailing at special rate of postage provided for in the Act of February 28, 1925, embodied in Paragraph 4, Section 538, P. L. and R., authorized April 1, 1926.

LATTICE POINT COVERINGS BY PLANE FIGURES

IVAN NIVEN, University of Oregon, and H. S. ZUCKERMAN, University of Washington

1. Let S be a bounded set of points in the Euclidean plane with a unit distance defined. If a rectangular coordinate system is imposed a certain number of points of S are lattice points, i.e., points with integral coordinates. Let $m(S)$ be the minimum number of lattice points, and $M(S)$ the maximum number, for all possible choices of the coordinate system. For example if S is a unit disk, i.e., a circle of diameter 1 with interior, then $m(S)=0$ and $M(S)=2$. These definitions of $m(S)$ and $M(S)$ could be given in terms of a fixed rectangular coordinate system, with the set S being rotated and translated freely in the plane. This alternative formulation is useful in proofs.

If a set S satisfies $m(S)\geqq 1$, we say that S has the *lattice point covering property* because S covers at least one lattice point no matter how the coordinate system is imposed. This paper gives necessary and sufficient conditions for the lattice point covering property in the cases of three types of simple plane figures, with boundary and interior included. The three types are the ellipse, the triangle and the parallelogram, treated in Sections 2, 3, 4, respectively.

For the circle plus interior, denoted by C say, it is clear that C has the lattice point covering property if and only if $r\geqq\sqrt{2}/2$, where r is the radius of the circle. Another relatively easy case is that of the rectangle, say of dimensions a by b with $a\leqq b$. Necessary and sufficient conditions that a rectangle have the lattice point covering property are that $a\geqq 1$ and $b\geqq\sqrt{2}$; (see [1]).

2. The Ellipse.

THEOREM 1. *An ellipse with axes of lengths $2a$ and $2b$ has the lattice point covering property if and only if $4a^2b^2\geqq a^2+b^2$.*

Alternative statement: *an ellipse has the lattice point covering property if and only if the point $(\frac{1}{2},\frac{1}{2})$ is inside or on the ellipse when a rectangular coordinate system is imposed with origin at the center of the ellipse and coordinate axes coinciding with the axes of the ellipse.*

Proof. The equivalence of the two statements follows at once from the equation $x^2/a^2+y^2/b^2=1$ for the ellipse with the coordinate system imposed.

Assume first that $4a^2b^2\geqq a^2+b^2$. Consider a lattice of points in the uv plane: $u=0$, $v=0$; $u=1$, $v=0$; $u=0$, $v=1$; etc. Impose this lattice of points on the xy plane where the ellipse E has the equation $x^2/a^2+y^2/b^2=1$. Let m denote the slope (relative to the xy coordinate system) of the u-axis. We can suppose that $-1<m\leqq 1$ if we interchange u and v when appropriate.

The lines of lattice points lie on $v=n$ relative to the uv coordinate system, where n is an integer. For an appropriate choice of n the line of lattice points $v=n$ will have equation

$$y = mx + k \text{ with } -\tfrac{1}{2}\sqrt{1+m^2} < k \leqq \tfrac{1}{2}\sqrt{1+m^2}$$

because $y=mx+k_1$ and $y=mx+k_2$ are a unit distance apart if $|k_1-k_2|=\sqrt{1+m^2}$.

Now consider the possible intersections of $y=mx+k$ with the ellipse E. When y is eliminated the equations give

$$x = \{-mka^2 \pm ab(b^2 + m^2a^2 - k^2)^{1/2}\}/(b^2 + m^2a^2). \tag{1}$$

The condition $4a^2b^2 \geqq a^2+b^2$ implies

$$a^{-2} + b^{-2} \leqq 4, \qquad a^{-2} < 4, \qquad b^{-2} < 4,$$

$$k^2 < \frac{1}{4}(1 + m^2) = \frac{1}{4} + \frac{m^2}{4} < b^2 + m^2a^2.$$

Hence we see from (1) that there are two points of intersection, say (x_1, mx_1+k) and (x_2, mx_2+k). We prove that the distance between these points is at least one, and it follows that the ellipse covers a lattice point. Denoting this distance by d we see that

$$d^2 = (1 + m^2)(x_1 - x_2)^2 = 4a^2b^2(1 + m^2)(b^2 + m^2a^2 - k^2)/(b^2 + m^2a^2)^2.$$

Using $k^2 \leqq (1+m^2)/4$ and direct calculation we get

$$(d^2 - 1)(b^2 + m^2a^2)^2 \geqq (m^4a^2 + b^2)(4a^2b^2 - a^2 - b^2) + 4m^2a^2b^2(a^2 + b^2 - 1).$$

The right member is not negative because $4a^2b^2 \geqq a^2+b^2$ and because this together with $a^2+b^2 \geqq 2ab$, $a>0$, $b>0$ imply

$$4a^2b^2 \geqq 2ab, \qquad 2ab \geqq 1, \qquad a^2 + b^2 \geqq 1.$$

Hence $d \geqq 1$ is established.

Conversely, if $4a^2b^2 < a^2+b^2$ then the point $x=\frac{1}{2}$, $y=\frac{1}{2}$ is outside the ellipse $x^2/a^2+y^2/b^2=1$. Then set the lattice of points down on the ellipse with $u=0$, $v=0$ at $x=-\frac{1}{2}$, $y=-\frac{1}{2}$ and with $u=1$, $v=0$ at $x=\frac{1}{2}$, $y=-\frac{1}{2}$. Then the ellipse contains no lattice point (u, v).

3. The triangle.

THEOREM 2. *A triangle with sides of lengths a, b, c, with $a \leqq b \leqq c$, has the lattice point covering property if and only if $2\Delta(c-1) \geqq c^2$ where Δ is the area of the triangle.*

It is convenient to break the proof into a number of steps. We let $A_1A_2A_3$ be an arbitrary triangle, a_i the length of the side opposite A_i, h_i the length of the altitude through A_i, α_i the size of the angle at A_i, and Δ the area. Throughout the letters i, j, k will denote the three distinct integers 1, 2, 3 in some order.

We define three numbers w_i as follows. If $h_i<1$ then $w_i=0$. If $h_i \geqq 1$ then w_i is the length of the segment P_iQ_i where P_i lies on A_iA_j, Q_i on A_iA_k, P_iQ_i is parallel to A_jA_k, and P_iQ_i is at a unit distance from A_jA_k.

LEMMA 3. *If $w_i \geqq 1$ for all $i=1, 2, 3$ then $A_1A_2A_3$ has the lattice point covering property.*

Proof. Let $A_1A_2A_3$ be set on the plane. Through each vertex A_i construct the four half lines emanating from A_i, two parallel (but in opposite directions) to

each coordinate axis. It is not hard to see that at least one of these twelve half lines will intersect the side of the triangle opposite the corresponding vertex. We can suppose the vertex is A_i and let K denote the intersection with A_jA_k. Lines parallel to A_iK through P_i and Q_i will intersect A_jA_k. Call these intersections

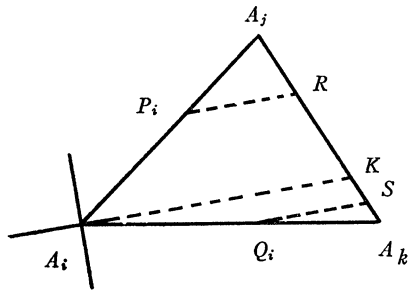

FIG. 1

R and S. Then RSQ_iP_i is a parallelogram contained in the triangle $A_1A_2A_3$. Since $w_i \geqq 1$, a line of lattice points parallel to A_iK will intersect P_iQ_i. Furthermore, this line will have on it a lattice point in RSQ_iP_i because $P_iR \geqq 1$.

LEMMA 4. (a) *If* $w_i > 0$ *then* $w_i - 1 = \{2\Delta - (a_i + h_i)\}/h_i$.
(b) *If* $w_i \geqq 1$ *and* $a_j \leqq a_i$ *then* $w_j \geqq 1$.

Proof. (a) We have $h_i > 1$. By a comparison of similar triangles, using $a_ih_i = 2\Delta$, we see that

$$\frac{h_i - 1}{h_i} = \frac{w_i}{a_i}, \qquad w_i = \frac{2\Delta - a_i}{h_i}, \qquad w_i - 1 = \frac{2\Delta - a_i - h_i}{h_i}.$$

(b) Since $w_i \geqq 1$ we have $h_i > 1$, and also we have $a_jh_j = 2\Delta = a_ih_i$, $h_j \geqq h_i$, and therefore $w_j > 0$. Furthermore

$$a_i - a_j \geqq (a_i - a_j)\sin\alpha_k, \quad a_i + a_j\sin\alpha_k \geqq a_j + a_i\sin\alpha_k, \quad a_i + h_i \geqq a_j + h_j.$$

Using these results and part (a) we find

$$w_j - 1 = \frac{2\Delta - (a_j + h_j)}{h_j} \geqq \frac{2\Delta - (a_i + h_i)}{h_j} = \frac{h_i}{h_j}(w_i - 1) \geqq 0.$$

LEMMA 5. *If* $w_i < 1$ *for some* $i = 1, 2, 3$, *then* $A_1A_2A_3$ *does not have the lattice point covering property.*

Proof. Let $m = 1, 2$, or 3 be such that $a_m = \max(a_1, a_2, a_3)$. Using Lemma 4(b) we see that $w_m < 1$. We also have $\alpha_m = \max(\alpha_1, \alpha_2, \alpha_3)$, and hence $\alpha_n < \pi/2$ if $n \neq m$. If $h_m < 1$ let T be the point A_m. If $h_m \geqq 1$ let T be the midpoint of P_mQ_m. Place the triangle on the plane with T at $(\frac{1}{2}, 1+\epsilon)$ and with the side opposite A_m on the line $y = \epsilon$. For ϵ sufficiently small but positive, the triangle $A_1A_2A_3$ covers no lattice point.

LEMMA 6. *If* $a_m=\max(a_1, a_2, a_3)$ *then the condition* $w_i\geqq 1$ *for all* $i=1, 2, 3$ *is equivalent to the condition* $2\Delta(a_m-1)\geqq a_m^2$.

Proof. Lemma 4(b) shows that $w_i\geqq 1$ for all $i=1, 2, 3$ is equivalent to the condition $w_m\geqq 1$. If $w_m\geqq 1$ then using Lemma 4(a) we obtain

$$2\Delta(a_m - 1) - a_m^2 = 2\Delta a_m - a_m h_m - a_m^2 = a_m(2\Delta - h_m - a_m)$$
$$= a_m h_m(w_m - 1) \geqq 0.$$

Conversely if $2\Delta(a_m-1)\geqq a_m^2$ then

$$a_m^2(h_m - 1) > a_m^2 h_m - a_m^2 - a_m h_m = 2\Delta(a_m - 1) - a_m^2 \geqq 0.$$

Therefore $h_m>1$, hence $w_m>0$, and by Lemma 4(a)

$$w_m - 1 = \frac{2\Delta - (a_m + h_m)}{h_m} = \frac{2\Delta a_m - a_m^2 - a_m h_m}{a_m h_m} = \frac{2\Delta(a_m - 1) - a_m^2}{2\Delta} \geqq 0.$$

These lemmas together imply Theorem 2.

4. The parallelogram. Let $ABCD$ be a parallelogram whose smaller interior angle γ, say at A, satisfies $0<\gamma<\pi/2$; thus $ABCD$ is not a rectangle. Let a be the distance between the parallel lines AB and CD, and b the distance between AD and BC.

LEMMA 7. *If* $a<1$ *or* $b<1$ *the parallelogram does not have the lattice point covering property.*

Proof. The parallelogram can be fitted between, for example, the lines $y=0$ and $y=1$.

LEMMA 8. *Assume* $a\geqq 1$ *and* $b\geqq 1$. *Let a rectangular coordinate system be imposed on* $ABCD$, *and define the angle* θ *thus: consider the four half lines emanating from* A, *parallel to the axes; let* AK *be that one of the four half lines such that* K *is on the same side of the line* AB *as are* C *and* D, *and such that the angle* BAK, *denoted by* θ, *satisfies* $0<\theta\leqq\pi/2$. *If* $\theta\geqq\gamma$, *i.e. if* AK *does not intersect the interior of the parallelogram, then there is a lattice point inside or on* $ABCD$.

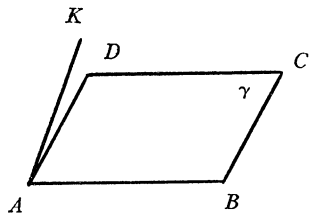

FIG. 2

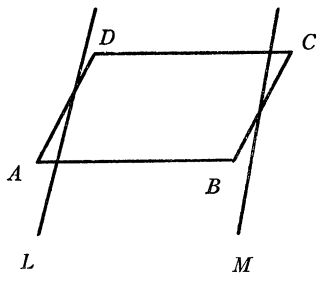

FIG. 3

Proof. Suppose there is no such lattice point. The lattice lines which are parallel to AK intersect the line AB extended at infinitely many points, any two adjacent points being at a distance $\csc\theta$. However, the distance between the parallel lines AD and BC being b, we see that

$$\text{length } AB = b\cdot\csc\gamma \geqq b\csc\theta \geqq \csc\theta.$$

Hence some lattice line parallel to AK intersects the line segment AB. Let L be the rightmost such line, i.e. the one whose intersection with the segment AB is closest to B. Let M be the next such lattice line to the right, so that M does not intersect the segment AB. Now L cannot intersect the segment DC since the distance between AB and DC is $a\geqq 1$, and we are presuming that there is no lattice point inside or on $ABCD$. Furthermore L cannot intersect the segment BC since $\theta\geqq\gamma$, and L coincident with BC is not possible. Hence L intersects AD. For convenience label the regions of the plane outside the parallelogram, bounded by the extensions of the sides, by (1), (2), $\cdots$, (8) as shown in Fig. 4.

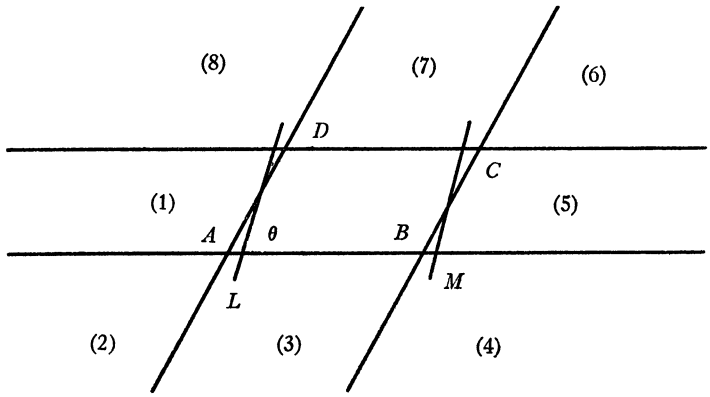

FIG. 4

No point of the parallelogram belongs to any of these regions (1), $\cdots$, (8). We assign the boundaries between regions in any fashion with one exception: the extension of CD beyond the point D belongs to region (1). Since $a\geqq 1$ there is a lattice point on L in region (1). Let P be such a point closest to the line CD. Let Q be the lattice point on M such that the distance $PQ=1$.

In which region is the point Q located? It cannot be in (7) or (8) since $\theta\leqq\pi/2$. It cannot be in (4), (5) or (6) since $b\geqq 1$. It cannot be in (2) or (3); in fact no point on M lies in (2) or (3) because $\theta\geqq\gamma$ and the line M intersects the line AB to the right of B. Hence Q lies in region (1). But this means that the line M has points in both regions (1) and (5), from which it follows that a segment of M of length at least 1 lies in $ABCD$. Thus we have a contradiction and Lemma 8 is proved.

LEMMA 9. *Let $ABCD$ be a parallelogram with $a\geqq 1$ and $b\geqq 1$ that does not have the lattice point covering property. Let a coordinate system be imposed on $ABCD$ so*

that no lattice point is inside or on the parallelogram. Then

$$a < \sqrt{2}\cdot\cos\left(\frac{\pi}{4} - \theta\right) \leqq \sqrt{2}, \qquad b < \sqrt{2}\cdot\cos\left(\frac{\pi}{4} - \gamma + \theta\right) \leqq \sqrt{2},$$

where θ is defined as in Lemma 8.

Proof. Note that $0<\theta<\gamma$ by Lemma 8. Slide the parallelogram down on the lines AD and BC extended until a lattice point appears on the line segment AB. With the parallelogram in this position there is at least one lattice point P on the segment AB but no lattice points in the part of the parallelogram off this segment. Let Q be the lattice point such that $PQ=1$ and PQ makes an angle θ with PB. Let S be the lattice point such that $PS=1$, $QS=\sqrt{2}$, and the turn from the direction PQ to PS is counterclockwise. Let R be the lattice point diagonally opposite P in the unit square $PQRS$. We prove that Q lies to the right

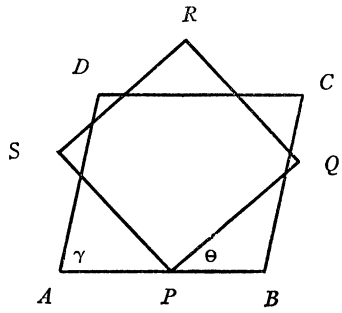

FIG. 5

of BC, i.e. on that side of BC away from AD; that S lies to the left of AD, i.e. on that side of AD away from BC; and that R lies above DC, i.e. on that side of DC away from AB.

First since $0<\theta<\gamma$ we see that Q lies above the line AB and to the right of AD. Also $a>1$ so Q cannot lie above CD. Hence Q lies to the right of BC. Likewise S is above AB, below CD, and to the left of BC. Hence S is to the left of AD. Now $b\geqq 1$ implies that R lies between the lines AD and BC since $SR=RQ=1$. But R does not lie below AB, and so R lies above CD.

Now impose a new coordinate system with the origin at P, the positive end of the x axis along PB away from A, and the positive end of the y axis from P towards CD. Then P is (0, 0) and R is $(\cos\theta-\sin\theta, \cos\theta+\sin\theta)$. But R lies above CD, so $\cos\theta+\sin\theta>a$ and this establishes the first part of the lemma.

Next impose a new xy coordinate system, discarding the preceding one, with origin at Q, x axis parallel to BC and with positive end in the direction B to C, and with positive end of the y axis from Q towards AD. Then Q is (0, 0) and S is

$$\left(\cos\left(\frac{\pi}{2}-\gamma+\theta\right)-\sin\left(\frac{\pi}{2}-\gamma+\theta\right),\right.$$
$$\left.\cos\left(\frac{\pi}{2}-\gamma+\theta\right)+\sin\left(\frac{\pi}{2}-\gamma+\theta\right)\right).$$

But S is to the left of AD and Q to the right of BC, and so

$$\cos\left(\frac{\pi}{2}-\gamma+\theta\right)+\sin\left(\frac{\pi}{2}-\gamma+\theta\right)>b.$$

This implies the second inequality of Lemma 9, and thus the proof is complete. The following result follows at once.

LEMMA 10. *If $a\geqq 1$ and $b\geqq\sqrt{2}$ (or $a\geqq\sqrt{2}$ and $b\geqq 1$) then $ABCD$ has the lattice point covering property.*

LEMMA 11. *Assume that $1\leqq a<\sqrt{2}$ and $1\leqq b<\sqrt{2}$. Define $\alpha=\arccos a/\sqrt{2}$ and $\beta=\arccos b/\sqrt{2}$, so that $0<\alpha\leqq\pi/4$ and $0<\beta\leqq\pi/4$. If $ABCD$ does not have the lattice point covering property then $\alpha+\beta+\gamma>\pi/2$.*

Proof. By Lemma 9 we see that

$$\cos\left(\frac{\pi}{4}-\gamma+\theta\right)>\cos\beta \quad\text{and}\quad \cos\left(\frac{\pi}{4}-\theta\right)>\cos\alpha,$$

$$\left|\frac{\pi}{4}-\gamma+\theta\right|<\beta \quad\text{and}\quad \left|\frac{\pi}{4}-\theta\right|<\alpha,$$

$$-\beta<\frac{\pi}{4}-\gamma+\theta<\beta \quad\text{and}\quad -\alpha<\frac{\pi}{4}-\theta<\alpha,$$

$$\frac{\pi}{4}-\alpha<\theta<\gamma+\beta-\frac{\pi}{4}, \qquad \alpha+\beta+\gamma>\frac{\pi}{2}.$$

THEOREM 12. *Let a and b be the distances between the pairs of opposite sides, say with $a\leqq b$, of a parallelogram $ABCD$ with an interior angle $\gamma<\pi/2$. The parallelogram has the lattice point covering property if and only if $a\geqq 1$ and one of the following conditions holds:*

(i) $b\geqq\sqrt{2}$;

(ii) $b<\sqrt{2}$ *and* $\alpha+\beta+\gamma\leqq\pi/2$, *where* $\alpha=\arccos a/\sqrt{2}$ *and* $\beta=\arccos b/\sqrt{2}$.

Proof. For convenience we use the contrapositive form of the statement: a parallelogram does not have the lattice point covering property if and only if $a<1$, or $1\leqq a\leqq b<\sqrt{2}$ with $\alpha+\beta+\gamma>\pi/2$. These conditions are necessary because of Lemmas 10 and 11.

That the condition $a<1$ is sufficient follows from Lemma 7. So we assume

$1 \leqq a \leqq b < \sqrt{2}$ and $\alpha+\beta+\gamma > \pi/2$ and prove that the parallelogram does not have the lattice point covering property. The second inequality along with $\alpha > 0$, $\beta > 0$, and $\gamma < \pi/2$ implies

$$\frac{\pi}{4} - \alpha < \frac{\pi}{4} + \alpha, \qquad \frac{\pi}{4} - \alpha < \beta + \gamma - \frac{\pi}{4},$$

$$\gamma - \beta - \frac{\pi}{4} < \frac{\pi}{4} + \alpha, \qquad \gamma - \beta - \frac{\pi}{4} < \beta + \gamma - \frac{\pi}{4}.$$

Hence we can choose a real number θ satisfying

$$\max\left(\frac{\pi}{4} - \alpha, \gamma - \beta - \frac{\pi}{4}\right) < \theta < \min\left(\frac{\pi}{4} + \alpha, \beta + \gamma - \frac{\pi}{4}\right).$$

This real number θ also satisfies

$$0 < \theta < \gamma, \qquad \left|\frac{\pi}{4} - \theta\right| < \alpha, \qquad \left|\frac{\pi}{4} - \gamma + \theta\right| < \beta. \tag{2}$$

To establish these we note first that since $\alpha \leqq \pi/4$, $\beta \leqq \pi/4$,

$$0 \leqq \frac{\pi}{4} - \alpha < \theta < \beta + \gamma - \frac{\pi}{4} \leqq \gamma.$$

The second and third inequalities (2) follow directly from

$$\frac{\pi}{4} - \alpha < \theta < \frac{\pi}{4} + \alpha \quad \text{and} \quad \gamma - \beta - \frac{\pi}{4} < \theta < \beta + \gamma - \frac{\pi}{4}.$$

Now we start with a unit square $RSTU$ of lattice points and construct a

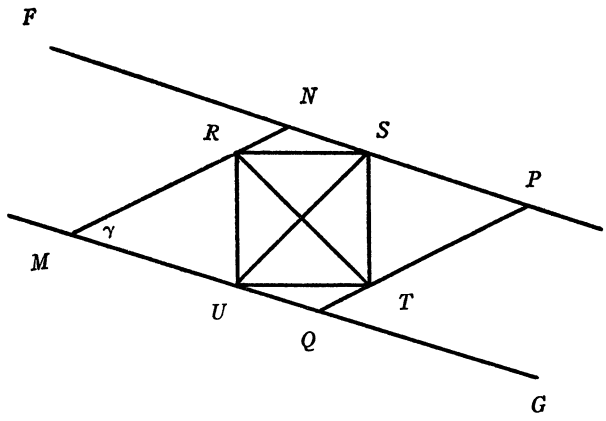

FIG. 6

parallelogram $MNPQ$ as shown in Fig. 6. Here FS and GU are parallel lines such that angle FSR=angle $GUT=\theta$. Also angle $RMU=\gamma$, N is the intersection of FS and MR, P is on FS, Q is on GU, and PQ passes through T. It can be seen that the parallelogram $MNPQ$ covers no lattice points other than R, S, T, U because N and Q lie between the lines UR and ST extended, and M and P lie between RS and TU extended. We see that

$$\text{angle } RTQ = \frac{\pi}{4} + \gamma - \theta, \quad \text{angle } USN = \theta + \frac{\pi}{4}.$$

Hence the distance between MN and PQ is, by use of (2),

$$RT \sin\left(\frac{\pi}{4} + \gamma - \theta\right) = \sqrt{2} \cos\left(\frac{\pi}{4} - \gamma + \theta\right) > \sqrt{2} \cos \beta = b.$$

Also the distance between NP and MQ is

$$US \sin\left(\theta + \frac{\pi}{4}\right) = \sqrt{2} \cos\left(\frac{\pi}{4} - \theta\right) > \sqrt{2} \cos \alpha = a.$$

But the parallelogram $ABCD$ described in the theorem has altitudes a and b and angle γ, and thus $ABCD$ can be inscribed inside $MNPQ$, with no boundary point of $MNPQ$ lying inside or on $ABCD$. This establishes that $ABCD$ does not have the lattice point covering property.

THEOREM 13. *Let a and b be the distances between the pairs of opposite sides, say with $a \leqq b$, of a parallelogram or rectangle with an interior angle $\gamma \leqq \pi/2$. The figure has the lattice point covering property if and only if $a \geqq 1$ and one of the following conditions holds:*

(i) $b \geqq \sqrt{2}$;

(ii) $b < \sqrt{2}$ *and* $2 \cos \gamma \geqq a\sqrt{2-b^2} + b\sqrt{2-a^2}$.

Proof. This differs from Theorem 12 in the formulation of condition (ii) and in the extension to $\gamma = \pi/2$. Now a rectangle of dimensions a by b with $a \leqq b$ has the lattice point covering property if and only if $a \geqq 1$ and $b \geqq \sqrt{2}$. (See [1].) This is what both Theorems 12 and 13 reduce to in case $\gamma = \pi/2$, because condition (ii) is satisfied in neither theorem. For $\gamma < \pi/2$ it is easy to establish the equivalence of condition (ii) in the two theorems. For $\alpha+\beta+\gamma \leqq \pi/2$ implies

$$\alpha + \beta \leqq \frac{\pi}{2} - \gamma, \quad \sin(\alpha + \beta) \leqq \sin\left(\frac{\pi}{2} - \gamma\right) = \cos \gamma,$$

$$\frac{\sqrt{2 - a^2}}{\sqrt{2}} \cdot \frac{b}{\sqrt{2}} + \frac{a}{\sqrt{2}} \cdot \frac{\sqrt{2 - b^2}}{\sqrt{2}} \leqq \cos \gamma,$$

and this gives condition (ii) of Theorem 13; also the steps of this argument are reversible.

Theorem 13 can be formulated in nongeometric language in the following

way. Consider the inequalities

$$(3)\qquad \begin{aligned} a_1 &\leqq c_{11}x + c_{12}y \leqq a_1 + a, \\ b_1 &\leqq c_{21}x + c_{22}y \leqq b_1 + b, \end{aligned}$$

and the equalities

$$(4)\qquad c_{11}^2 + c_{12}^2 = 1, \qquad c_{21}^2 + c_{22}^2 = 1, \qquad |c_{11}c_{21} + c_{12}c_{22}| = c.$$

THEOREM 14. *Let a, b and c be real numbers satisfying the conditions $a>0$, $b>0$, $a\leqq b$, $0\leqq c\leqq 1$. The inequalities* (3) *have a solution in integers x, y for every set of real numbers a_1, b_1, c_{11}, c_{12}, c_{21}, c_{22} satisfying* (4) *if and only if $a\geqq 1$ and one of the following conditions holds*:

(i) $b\geqq\sqrt{2}$;

(ii) $b<\sqrt{2}$ *and* $2c\geqq a\sqrt{2-b^2}+b\sqrt{2-a^2}$.

Supported in part by N.S.F. Contracts GP 3801 (I. Niven) and GP 3788 (H. S. Zuckerman).

Added in proof: The proof of Lemma 3 is incorrect. A correction will be forthcoming.

PRODUCTS OF POINTS—SOME SIMPLE ALGEBRAS AND THEIR IDENTITIES

TREVOR EVANS, Emory University

Introduction. The collection of algebras we introduce here were discovered during a study of groupoids satisfying the identity

$$(xy)(yz) = y \quad \text{for all } x, y, z.$$

The original question was whether there existed a nontrivial groupoid satisfying this identity. Rather surprisingly, it turns out that if a finite groupoid satisfies this identity, then it must contain a square number of elements. From this, it is not too hard to find a model of the identity. If S is any nonempty set, then the multiplication

$$(a, b)\cdot(c, d) = (b, c)$$

defined on the set of all ordered pairs of elements of S does indeed satisfy $xy\cdot yz = y$, identically.

This suggests that we look at other multiplications of the same type. On a set S, we can always introduce two different associative multiplications by defining a product ab to be a, for each a, b in S or by defining ab to be b, for each a, b in S. There are sixteen analogues of these multiplications on the set of all

ordered pairs of elements of S, each of which is described by a rule of the form

$$(a, b)\cdot(c, d) = (\ ,\)$$

where the right-hand side $(\ ,\)$ is some ordered pair selected from a, b, c, d. Because of the interpretation of each of these products as a geometric construction on the graph of the cartesian product $S\times S$, we call them *products of points*.

Although the product $(a, b)\cdot(c, d)=(b, c)$ is probably the most interesting, several of the other multiplications yield identities worth studying. For example, the product

$$(a, b)\cdot(c, d) = (a, d)$$

is a special case of what is usually called a rectangular band [2]. This product satisfies the identities

$$(xy)z = x(yz), \qquad xyz = xz, \qquad x^2 = x \quad \text{for all } x, y, z.$$

That is, the product defines an idempotent semigroup satisfying the further identity $xyz=xz$. Conversely, any idempotent semigroup satisfying the identity $xyz=xz$ is a rectangular band.

As another example, consider the product

$$(a, b)\cdot(c, d) = (a, c).$$

Since $(a, x)\cdot(a, y)=(a, a)$ for all x, y in S, this groupoid is the union of disjoint constant semigroups $K_a=\{(a, x): x\in S\}$. Now this multiplication satisfies the identities

$$(xy)z = xz, \qquad x(yz) = xy \quad \text{for all } x, y, z,$$

and we show that any groupoid satisfying these identities is, in fact, a union of disjoint constant semigroups.

Our aim, in general, is to study the varieties of groupoids defined by the identities which these 'products of points' satisfy. By a *variety* of algebras, in general, we mean a class of algebras which can be described axiomatically by a set of identities. For example, the classes of groups, rings, lattices, loops, semigroups, etc. are all varieties. By a *variety of groupoids*, we mean the class of all groupoids satisfying some given set of identities. Not all types of algebras of interest form varieties (for example, fields do not) but varieties of algebras are on the one hand sufficiently general to be interesting to the universal algebraist and, on the other hand, sufficiently special to provide nontrivial theorems. The final section of the paper is a brief discussion of some of the problems in universal algebra which are illustrated by the algebras and identities we have studied.

1. The identity $xy\cdot yz=y$. The two products defined on the cartesian product $S\times S$

$$(a, b)(c, d) = (b, c)$$
$$(a, b)\circ(c, d) = (d, a)$$

are very closely related. In fact, $x \circ y = yx$. Thus, it will suffice to look at only one of them and we choose the first.

We digress briefly to note that not only can we express the ($\circ$) operation above in terms of this product—we can obtain all products of points in terms of this fundamental product. We will not give the complete list. Here are some examples. Let $x=(a, b)$, $y=(c, d)$. Then,

$$(xx)x = (a, a), \qquad x(xx) = (b, b), \qquad (xy)x = (c, a),$$
$$(yx)y = (a, c), \qquad x(yy) = (b, d), \qquad y(xx) = (d, b).$$

It is also true, but not quite so easy to see, that the $(a, b)(c, d)=(b, c)$ product (and the ($\circ$) operation) are the only products of points which can be used in this way to construct all such products. We cannot construct the pair (b, c) from (a, b), (c, d) and the ($*$) operation $(a, b) * (c, d)=(a, d)$, for example, since any repeated product using the ($*$) operation must always yield a pair having a or c as its first component, and b or d as its second.

Our main concern in the study of the $(a, b) \cdot (c, d)=(b, c)$ product, however, is not the above property but an interesting identity this product satisfies. For any (a, b), (c, d), (e, f) in $G=S\times S$, we have

$$\{(a, b)(c, d)\}\{(c, d), (e, f)\} = (b, c)(d, e)$$
$$= (c, d)$$

and hence this product satisfies

$$(xy)(yz) = y \quad \text{for all } x, y, z \text{ in } G.$$

Clearly, if S is finite and contains n elements, then this groupoid G contains n^2 elements. The converse of this statement is also true. Let G be a finite groupoid satisfying the identity $xy \cdot yz = y$, for all x, y, z in G. Let $x=tu$, $y=uv$ in this identity. Then $(tu \cdot uv)(uv \cdot z)=uv$ for all t, u, v, z in G. That is

$$u(uv \cdot z) = uv, \quad \text{for all } u, v, z \text{ in } G.$$

Similarly, we obtain the identity

$$(x \cdot uv)v = uv, \quad \text{for all } x, u, v \text{ in } G.$$

For each a in G, we define, as usual, the *left* and *right multiplications* L_a, R_a by

$$xL_a = ax, \qquad xR_a = xa, \quad \text{for all } x \text{ in } G.$$

In terms of these mappings, the above identities may be written

$$L_uR_zL_u = L_u, \qquad R_vL_xR_v = R_v, \quad \text{for all } x, u, v, z \text{ in } G.$$

We will write $r(P)$ for the number of elements of the range of a mapping $P: G \to G$. From $L_uR_zL_u = L_u$, it follows that $r(L_u) \leqq r(R_z)$ and from $R_vL_xR_v = R_v$, we obtain $r(R_v) \leqq r(L_x)$. Hence, $r(L_x) = r(R_y)$, for all x, y in G. Let n denote the number of elements in the range of each left and right multiplication.

Now let a be any element in G and let b be any element in the range of R_a. That is, $ua=b$, for some u in G. Since $(x\cdot ua)a=ua$, for all x in G, we obtain

$$(xb)a = b \quad \text{for all } x \text{ in } G.$$

But xb takes on n different values as x ranges over G. Hence, R_a maps at least n different elements on b.

Let y be any element mapped onto b by R_a. That is, $ya=b$. Now, if $x\in G$, $xy\cdot ya=(xy)b$. But $xy\cdot ya=y$. Hence, $y=(xy)b$. That is, y is in the range of R_b. Since the range of R_b contains n elements, there are at most n elements mapped onto b by R_a.

It follows that R_a maps exactly n elements onto each element in its range. Since R_a has n elements in its range, G contains n^2 elements.

THEOREM. *A finite model of the identity $xy\cdot yz=y$, for all x, y, z contains n^2 elements, for some positive integer n. Conversely, for each positive integer n, there is a model of the identity containing n^2 elements.*

The groupoid on $S\times S$ with the multiplication $(a, b)\cdot(c, d)=(b, c)$ satisfies many more identities then merely $xy\cdot yz=y$. It is easy to find others such as

$$(x\cdot x^2)(y^2\cdot y) = xy, \qquad (xy)^2(xy) = x\cdot x^2,$$
$$(x\cdot x^2)^2 = x\cdot x^2, \qquad (x\cdot y^2)(z\cdot w^2) = yz^2.$$

In fact, we can find enough identities to characterize completely groupoids of this type.

THEOREM. *Let G be a groupoid satisfying the identities*
(i) $xy\cdot yz=y$ *for all* x, y, z
(ii) $(x\cdot x^2)(y^2\cdot y)=xy$ *for all* x, y
(iii) $(xy)^2(xy)=x\cdot x^2$ *for all* x, y.
Then G is isomorphic to the groupoid on S^2 (where S is the set of idempotents of G) with multiplication $(a, b)\cdot(c, d)=(b, c)$.

Proof. From (i) $x^2\cdot x^2=x$ and hence, putting $y=x^2$ in (ii), we obtain

$$(x\cdot x^2)^2 = x\cdot x^2 \quad \text{for all } x \text{ in } G.$$

Hence, for each x, $x\cdot x^2$ is an idempotent in G. Let S be the set of all such idempotents. Since $(xy)^2(xy)=x\cdot x^2$, we see that any element in S may also be written as $v^2\cdot v$ for some v in G. Hence, any element in $S\times S$ may be written as $(u\cdot u^2, v^2\cdot v)$ for some u, v in G.

Now $u\cdot u^2=(uv)^2(uv)$. Furthermore, $v^2\cdot v=(uv\cdot vw)^2(uv\cdot vw)$ by identity (i) and $(uv\cdot vw)^2\cdot(uv\cdot vw)=(uv)(uv)^2$ by identity (iii). Hence, $(u\cdot u^2, v^2\cdot v)=((uv)^2(uv), (uv)(uv)^2)$ and so any element in $S\times S$ may be written as $(x^2\cdot x, x\cdot x^2)$ for some x in G.

Let us now introduce on $S\times S$, the multiplication $(a, b)\cdot(c, d)=(b, c)$. We will show the correspondence

$$(x^2\cdot x, x\cdot x^2)\leftrightarrow x$$

is an isomorphism between this groupoid on $S\times S$ and the groupoid G.

The correspondence is certainly one-one since $x=y$ implies $(x^2\cdot x,\ x\cdot x^2)=(y^2\cdot y,\ y\cdot y^2)$ and $(x^2\cdot x,\ x\cdot x^2)=(y^2\cdot y,\ y\cdot y^2)$ implies $(x^2\cdot x)(x\cdot x^2)=(y^2\cdot y)(y\cdot y^2)$ which, in turn, by identity (i) implies $x=y$.

To see that it is an isomorphism, consider the product

$$(x^2\cdot x,\ x\cdot x^2)(y^2\cdot y,\ y\cdot y^2)\ =\ (x\cdot x^2,\ y^2\cdot y)$$

in the groupoid on $S\times S$. Now

$$(x\cdot x^2,\ y^2\cdot y)\ =\ ((xy)^2(xy),\ (xy)(xy)^2)$$

by identity (iii) and by our earlier result $v^2\cdot v=(uv)(uv)^2$. But $((xy)^2(xy),\ (xy)(xy)^2)$ corresponds to xy in G under the one-one mapping described above. Hence, the mapping is an isomorphism.

REMARKS. The identities listed in the preceding theorem are not necessarily the simplest which will characterize this particular product of points; it may be that one other identity, in addition to $xy\cdot yz=y$ is sufficient. The identity $xy\cdot yz=y$ by itself is not sufficient since it can be shown that the free groupoid on one generator satisfying this identity is infinite.

The multiplication $(a,\ b)\cdot(c,\ d)=(d,\ a)$ which we mentioned at the beginning of this section also satisfies the identity $(xy)(yz)=y$ and hence a completely similar analysis may be carried out for this product.

2. Rectangular bands. We remarked earlier that on a nonempty set S we can always construct two semigroups

(i) *the left-zero semigroup on S*, with multiplication given by $ab=a$, for all $a,\ b$ in S,

(ii) *the right-zero semigroup on S*, with multiplication given by $ab=b$, for all $a,\ b$ in S.

The groupoid on $S\times S$ with multiplication

$$(a,\ b)\cdot(c,\ d)\ =\ (a,\ d)$$

is simply the direct product of the left and right-zero semigroups on S and similarly, the multiplication $(a,\ b)(c,\ d)=(c,\ b)$ is the direct product of the right and left-zero semigroups on S. Hence, both of these products on $S\times S$ are associative and, in fact, satisfy the further identities

$$x^2\ =\ x,\qquad xyz\ =\ xz\quad \text{for all } x,\ y,\ z.$$

(We omit parentheses in products such as xyz, from now on, since the multiplication is associative.)

By a *rectangular band*, we mean a semigroup having as elements all ordered pairs in $S\times T$, where S, T are any sets, and with a product defined by $(s_1,\ t_1)\cdot(s_2,\ t_2)=(s_1,\ t_2)$. The product defined above on $S\times S$ is the special case $S=T$. Furthermore, the identities $x^2=x$, $xyz=xz$ are also satisfied by any rectangular band. We now prove the converse of this.

THEOREM. *A semigroup satisfying the identities* $xyz=xz$ *for all* x, y, z; $x^2=x$ *for all* x, *is a rectangular band.*

Proof. Let B be a semigroup satisfying these identities. We first construct two homomorphic images of B which are left and right-zero semigroups, respectively.

Consider the relation λ on B defined by

$$x \lambda y \text{ if and only if } xt = yt, \quad \text{for all } t.$$

In terms of left multiplications, this condition may be written as $L_x=L_y$. Clearly, λ is an equivalence relation on B. In addition if $x \lambda y$ and $z \lambda w$, then $(xz)t=xt=yt=(yw)t$ for all t in B. Hence, $xz \lambda yw$. That is, λ is a congruence relation on B. Since $(xy)t=xt$ for all x, y, t in B, $xy \lambda x$. That is, if C_x denotes the congruence class containing x, then $C_{xy}=C_x$. Hence, in the quotient semigroup B_λ, $C_xC_y=C_x$ and so B_λ is a left-zero semigroup.

Similarly, we define a congruence relation on B by $x \rho y$ if and only if $tx=ty$ for all t. The corresponding quotient algebra B_ρ is a right-zero semigroup.

Consider the direct product of B_λ and B_ρ. If C_x denotes the λ-congruence class of B containing x and D_x denotes the ρ-congruence class of B containing x, then the mapping

$$\alpha: x \to (C_x, D_x)$$

is a homomorphism of B into $B_\lambda \times B_\rho$. In fact, it is onto $B_\lambda \times B_\rho$, since $(C_x, D_y) = (C_{xy}, D_{xy})$. It is also one-one since if $(C_x, D_x)=(C_y, D_y)$, then $xt=yt$, $tx=ty$ for all t. Hence, $x=xx=yx=yy=y$.

This completes the proof. We have shown that B is isomorphic to the rectangular band on the cartesian product of the set of all C_x's and the set of all D_x's.

There is clearly a very close connection between the product discussed in this section and the product $(a, b)\cdot(c, d)=(b, c)$ of the preceding section. An abstract setting for this connection is provided by the following theorem:

Let E *be an idempotent semigroup satisfying the further identity* $xyz=xz$, *for all* x, y, z, *and let* $\theta: E \to E$ *be an anti-automorphism of* E *of period two. Then the operation* $(\circ)$ *defined by* $x \circ y=(xy)\theta$ *satisfies the identity*

$$(x \circ y) \circ (y \circ z) = y.$$

The proof is purely computational. We remark that this result implies that a finite idempotent semigroup satisfying $xyz=xz$ for all x, y, z and having an anti-automorphism of order two necessarily contains a square number of elements.

3. Unions of constant semigroups. The product in $S \times S$ given by

$$(a, b)\cdot(c, d) = (a, c)$$

satisfies the identities

$$xy\cdot z = xz, \qquad x\cdot yz = xy \quad \text{for all } x, y, z.$$

The subset K_a of all pairs in $S \times S$ of the form (a, x), a fixed, x any element in S, is closed under this multiplication and in fact, K_a is a constant semigroup since $(a, x) \cdot (a, y) = (a, a)$. (By a *constant semigroup*, we mean a set and a multiplication satisfying $xy = zw$ for all x, y, z, w, i.e. all products are the same. It is easy to verify that such a multiplication is associative.)

Furthermore, if K_a is the constant semigroup consisting of all pairs (a, x) and if K_b is the constant semigroup consisting of all pairs (b, x), then all products of an element in K_a and in K_b (in that order) are equal and lie in K_a.

We will now show that the two identities $xy \cdot z = xz$ and $x \cdot yz = xy$ characterize such unions of constant semigroups. Let G be a groupoid satisfying these identities. We begin by decomposing G by the equivalence relation

$$x \equiv y \text{ if and only if } xt = yt \quad \text{for all } t \text{ in } G$$

i.e. $x \equiv y$ if and only if $L_x = L_y$. If $x \equiv y$, then $t \cdot xt = t \cdot yt$ and so, by the identity $x \cdot yz = xy$, we have

$$tx = ty \quad \text{for all } t \text{ in } G.$$

It follows that this is a congruence relation on G since $x \equiv y$, $z \equiv w$ implies $xz = xw = yw$. The resulting quotient groupoid is a left zero semigroup since $xy \equiv x$.

Let C_u be the congruence class containing u and let x, y be any elements in C_u. Now $xy \cdot t = xt$ for all t and hence $xy \equiv x$. That is, $xy \in C_u$ and so C_u is a subgroupoid of G. Furthermore, if $x, y, z, w \in C_u$ then $xy = xw = zw$. Hence, C_u is a constant semigroup.

We now know that G is the union of disjoint constant semigroups and that these are congruence classes for a congruence relation yielding a left-zero semigroup as quotient algebra. The product of an element in C_u and one in C_v (in that order) belongs to C_u. Furthermore, for any x, z in C_u and y, w in C_v, $xy = zw$ since $xy = zy$ and $zy = zw$. Hence, the product of any element in C_u and any element in C_v is some fixed element in C_u.

This is all the information we can obtain from the identities $xy \cdot z = xz$ and $z \cdot yz = xy$ since if we take disjoint sets C_α, (α in some indexing set I), and pick, for each pair C_α, C_β, a fixed element $c_{\alpha\beta}$ in C_α, then the product on $\bigcup_{\alpha \in I} C_\alpha$ defined by $xy = c_{\alpha\beta}$ if $x \in C_\alpha$ $y \in C_\beta$ satisfies the identities $xy \cdot z = xz$, $x \cdot yz = xy$.

THEOREM. *A groupoid satisfies the identities $xy \cdot z = xz$, $x \cdot yz = xy$ if and only if it is the union of disjoint constant semigroups C_α where all products xy, with $x \in C_\alpha$, $y \in C_\beta$ are equal and belong to C_α.*

The multiplication on S^2,

$$(a, b) \cdot (c, d) = (d, b)$$

also satisfies the identities $xy \cdot z = xz$ and $x \cdot yz = xy$. In this case, the constant subsemigroups are the sets $\{(x, b) : x \in S\}$.

Two other 'products of points' yield to similar treatment. The multiplications

$$(a, b)\cdot(c, d) = (c, a) \qquad (a, b)\cdot(c, d) = (b, d)$$

each satisfies the identities $xy\cdot z = yz$, $x\cdot yz = xz$, for all x, y, z. If G is a groupoid satisfying these identities then the relation $x \equiv y$ if $R_x = R_y$ defines a congruence relation and the congruence classes are constant subsemigroups of G. In fact, we obtain a characterization of G completely analogous to the description in the preceding theorem with *left-zero semigroup* replaced by *right-zero semigroup*.

4. The other products. There are eight other products of points still to consider. The products

$$(a, b)\cdot(c, d) = (a, b), \qquad (a, b)\cdot(c, d) = (c, d)$$

yield left-zero and right-zero semigroups and there is nothing more to be said about them. The closely related products

$$(a, b)\cdot(c, d) = (b, a), \qquad (a, b)\cdot(c, d) = (d, c)$$

are more interesting. We will look at the first one only since the second may be treated similarly. The product $(a, b)\cdot(c, d) = (b, a)$ satisfies the identities

$$xy\cdot z = x, \qquad xy = xz \quad \text{for all } x, y, z.$$

Let G be a groupoid satisfying these identities. From the second, we see that $R_y = R_z$ and so all right multiplications of G are the same. From the first identity, $xR_yR_z = x$ and so the square of each right multiplication of G is the identity mapping. This is all that can be said about G since any groupoid which has all right multiplications equal and of order two necessarily satisfies the identities $xy\cdot z = x$, $xy = xz$. Using these properties of the right multiplications of G, it is a simple matter to construct a table for a groupoid satisfying these identities. One with three elements is shown in Fig. 1.

	a	b	c
a	a	a	a
b	c	c	c
c	b	b	b

FIG. 1.

The remaining four products are:

$$(a, b)\cdot(c, d) = (a, a), \qquad (a, b)\cdot(c, d) = (b, b)$$
$$(a, b)\cdot(c, d) = (c, c), \qquad (a, b)\cdot(c, d) = (d, d).$$

The first two satisfy the identity $xy = (xz)w$ and the second pair satisfies $xy = z(wy)$. We will consider only the identity $xy = (xz)w$. This implies the identities

$$xy = xz, \qquad xy\cdot y = xy, \qquad xy\cdot z = x\cdot yz \quad \text{for all } x, y, z.$$

Hence a groupoid G satisfying $xy=(xz)w$ is associative, all of its right multiplications are equal, $R_y=R_z$, and furthermore, are idempotent, $R_y^2=R_y$. The first two identities $xy=xz$, $xy\cdot y=xy$ are, in fact, equivalent to the single identity $xy=xz\cdot w$ and imply the associative law. These properties of the right multiplications again make it easy to construct examples of groupoids satisfying $xy=(xz)w$. One with three elements is shown in Fig. 2.

5. Some problems in universal algebra. We conclude by mentioning some examples of problems in universal algebra which are illustrated by the algebras we have studied above. We recall that a variety of groupoids is the class of all groupoids satisfying some given set of identities. By Birkhoff's Theorem, a class of groupoids V is a variety if and only if V is closed under taking subalgebras, homomorphic images and (unrestricted) direct products.

It seems very difficult to decide whether a variety of groupoids defined by a finite set of identities (or even by just one identity) actually contains nontrivial algebras. If $u(x, y, \ldots)=v(x, y, \ldots)$ is a groupoid identity and V is the variety of all groupoids satisfying it, then we see that (i) if both sides $u(x, y, \ldots)$, $v(x, y, \ldots)$ are products of variables then V contains constant semigroups (ii) if one side, say $v(x, y, \ldots)$ is simply one variable y, and the other side $u(x, y, \ldots)$ either begins or ends with y, then V contains either left- or right-zero semigroups. It is for this reason that we first studied the identity $xy\cdot yz=y$. It is the simplest identity for which it is not fairly easy to decide whether there is a groupoid satisfying it which contains more than one element. The similar-looking identities

$$x(y\cdot yz)=y, \qquad x(yy\cdot z)=y, \qquad (xy\cdot y)z=y, \qquad (x\cdot yy)z=y$$

have only trivial models.

The identity $xy\cdot yz=y$ is interesting for another reason. Let us call the set of orders of the finite algebras in a variety, the *spectrum* of the variety. What can be said about the spectrum of a variety? It is closed under multiplication since the direct product of two groupoids in a variety lies in the variety. Any set of positive integers generated multiplicatively by some finite set of primes is the spectrum of a variety of groupoids given by a single identity. For, let $p_1, p_2, \cdots, p_t$ be distinct primes and let $n=p_1p_2\cdots p_t$. The variety of abelian groups satisfying $x^n=1$ can be described as a variety of groupoids satisfying a single identity [4] and the groupoids in this variety have orders $p_1^{i_1}p_2^{i_2}\cdots p_t^{i_t}$; $i_s\geqq 0$. As another example, the variety of idempotent totally symmetric quasigroups may be defined as a variety of groupoids satisfying $x(xy)=y$, $xy=yx$,

$x^2=x$ and the spectrum of this variety consists of all positive integers of the form $6n+1$ or $6n+3$, [1]. Our main result in Section 1 may be stated as: the spectrum of the groupoid variety defined by $xy\cdot yz=y$ is the set of all squares, $\{1, 4, 9, 16, \cdots\}$. The author has generalized this result [3] and obtained, for each positive integer n, a variety of groupoids having as spectrum all nth powers. For example, the variety defined by the identities $\{(x\cdot yz)(wz)\}(zt)=z$, $(x\cdot yz)w=(x\cdot yz)t$, for all x, y, z, w, t, has $\{1^3, 2^3, 3^3, \cdots\}$ as its spectrum.

A set of groupoid identities I is said to be *equationally complete* if it is maximal, that is, if for any groupoid identity $u=v$, either $u=v$ is deducible from I or the addition of $u=v$ to I yields a set of identities $I\cup\{u=v\}$ which has no nontrivial models. A variety is said to be equationally complete if its set of identities are equationally complete. Although it is known that there are uncountably many different equationally complete groupoid varieties [5], the problem of finding explicit sets of identities which are equationally complete is not easy. It would take us too far afield to prove it but we note that the variety of Section 1 defined by

$$xy\cdot yz = y, \qquad (xy)^2(xy) = xy, \qquad (x\cdot x^2)(x\cdot x^2) = x\cdot x^2$$

is equationally complete. None of the other varieties described are equationally complete. In fact, in each case, either the identity $xy=x$ or $xy=y$ may be added to the identities.

The problem of deciding whether a variety of groupoids is nontrivial, that is, contains nontrivial groupoids, is equivalent to the problem of deciding whether the identity $x=y$ follows from the defining identities of the variable. This is a special case of the problem of deciding, for an arbitrary identity, whether or not it holds in a particular variety. This question is easy to answer for all the varieties we study except for the variety defined by $xy\cdot yz=y$. For example, an identity is a consequence of the identities $(xy)z=xz$, $x(yz)=xy$ if and only if it is of the form $(x\cdots)\cdot(y\cdots)=(x\cdots)\cdot(y\cdots)$, where $x\cdots$ is any groupoid expression having x as the first letter. To decide when an identity is a consequence of $xy\cdot yz=y$ requires more sophisticated techniques and an analysis of the structure of a free groupoid satisfying this identity. The test may be described as follows. Let $w_1(x, y, z, \cdots)$, $w_2(x, y, z, \cdots)$ be groupoid 'words' in the variables $x, y, z, \cdots$. Let the identities $xy\cdot yz=y$, $x(xy\cdot z)=xy$, $(x\cdot yz)z=yz$ be used to shorten w_1 and w_2, in the sense that any occurrence of a left-hand side of one of these three identities in w_1 or w_2 be replaced by the corresponding right-hand side. Eventually, we obtain from w_1 and w_2 new expressions $w_1^*(x, y, z, \cdots)$, $w_2^*(x, y, z, \cdots)$ which cannot be shortened further in this manner. Then $w_1=w_2$ is an identity which is a consequence of $xy\cdot yz=y$ if and only if w_1^* and w_2^* are identical.

Added in Proof: After the abstract of [3] appeared, D. Knuth sent me a description of a number of different ways to approach the study of the identity $(xy)(yz)=y$ and he obtained a simpler set of identities than that given here to characterize the product, $(a, b)\cdot(c, d)=(b, c)$. A former student of mine, Marshall Saade, has found two identities which characterize the algebras of n-

tples described in [3] and has studied products of n-tples which correspond to the products of ordered pairs in this paper.

THE STELLATED FORMS OF THE SIXTEEN-CELL

B. L. CHILTON, State University of New York at Buffalo

Introduction. Let II be a regular or semi-regular convex polyhedron. A *stellated* form II′ of II is defined to be a polyhedron satisfying the following five restrictions:

(i) The faces of II′ must lie in the planes of the faces of II.

(ii) If F_1 and F_2 are congruent faces of II and are related by some symmetry operation of II, then the faces F_1' and F_2' of II′ which lie in the planes of F_1 and F_2, respectively, must likewise be congruent.

(iii) A face F' of II′ must possess at least the rotational symmetry of the face F of II in whose plane F' lies.

(iv) The parts included in any plane must all be "accessible" in the completed solid (i.e., on the "outside").

(v) Excluded from consideration shall be cases where the parts can be divided into two sets, each giving a solid with as much symmetry as the whole figure.

The above restrictions are based on conditions devised by J. C. P. Miller for the stellated forms of the icosahedron, $\{3, 5\}$.

The stellated forms of the five regular polyhedra have been exhaustively enumerated. The following table condenses the information. (Note that we

Name of convex polyhedron	*Number of stellated forms*	*Date(s) of discovery of nontrivial forms*	*Discoverer(s)*
Tetrahedron $\{3, 3\}$	1	—	—
Cube $\{4, 3\}$	1	—	—
Octahedron $\{3, 4\}$	2	1619	Kepler
Dodecahedron $\{5, 3\}$	4	1619, 1809	Kepler, Poinsot
Icosahedron $\{3, 5\}$	59	1900, 1938	Brückner, Coxeter *et al.*

consider a polyhedron to be a stellated form of itself; we distinguish it as "the trivial stellated form." It will be seen that two of the regular polyhedra possess no nontrivial stellated forms.)

In addition, the stellated forms of certain semiregular polyhedra have been investigated. D. Luke has worked with the rhombic dodecahedron. E. Hess and M. Brückner began the task of stellating the rhombic triacontahedron, and J. D. Ede has recently published a paper in which he has depicted a "complete face" of this polyhedron and in which he describes a number of its stellations.

The techniques developed by Coxeter and others to enumerate the stellated forms of the regular and semiregular polyhedra can be adapted for use on the four-dimensional regular polytopes (and conceivably on polytopes in Euclidean space of any number of dimensions). The purpose of the present article is to apply these techniques to the 16-cell, $\{3, 3, 4\}$. This has been chosen because it is the "simplest" four-dimensional regular polytope which possesses nontrivial stellated forms. (The simplex $\{3, 3, 3\}$ and the hypercube $\{4, 3, 3\}$ have "dihedral" angles $\leqq \pi/2$, which immediately rules out the possibility of nontrivial forms in these cases.) Miller's five conditions can easily be altered for our purposes, by replacing "face" by "cell" and "plane" by "hyperplane."

Stellating the 16-cell. The work is carried out by embedding the 16-cell in a Cartesian coordinate system, and finding the analytic representations of the planes, lines, and points of intersection of sets chosen from among the sixteen hyperplanes of its cells. The points of intersection of four or more hyperplanes are found to comprise four sets, classified as to arrangement and distance from the origin. These points are the vertices of the various stellated forms of the 16-

TABLE I. THE FOUR SETS OF VERTICES

Set	*Typical member*	*Number of vertices*	*Distance from origin*	*Convex polytope formed by set*

2	(1, 1, 1, 1)	16	2	$\{4, 3, 3\}$
3	(2, 2, 2, 0)	32	$2\sqrt{3}$	$t_1\gamma_4$
4	(4, 2, 2, 2)	64	$2\sqrt{7}$	Variant of $t_{0,1}\gamma_4$

cell. Complete information is given in Table I. Note that for each set of points, we have given the coordinates of a "typical" or "representative" point; all the points of the set can be found by listing all ordered quadruples obtainable from the given one by the operations of permutation and change of sign.

The vertices of Set 1 are the vertices of the original 16-cell, and because of the particular coordinates chosen, the edge is $2\sqrt{2}$. The convex hull formed by Set 2 is an 8-cell (hypercube) of edge 2. The vertices of Set 3 are the midpoints of the edges of a hypercube, and as such, form a cell-regular polytope consisting of 8 cuboctahedra and 16 tetrahedra, all of edge $2\sqrt{2}$. In the notation of [2, pp. 146, 158], this figure is $\left\{\begin{smallmatrix}3,3\\4\end{smallmatrix}\right\}$ or $\left\{\begin{smallmatrix}4\\3,3\end{smallmatrix}\right\}$. Set 4 gives a polytope that can best be

described as an "expanded" hypercube in the following sense: Each of the 8 cubic cells of a hypercube of edge 4 is translated bodily away from the center by such a distance that the faces originally in contact are separated by a square prism of height $2\sqrt{2}$ (so that there are 24 such prisms altogether). The vertices are distributed among 16 regular tetrahedra of edge $2\sqrt{2}$. This polytope, while not cell-regular, is a variant of the cell-regular polytope $t_{0,3}\gamma_4$.

Table II is intended as a supplement to the later tables. We consider the line of intersection of three or more cell-hyperplanes of the 16-cell. On this line will be found a number of points of Table I. These can be linearly ordered. What we refer to as a "1-region" in Table II is the segment of such a line between two

1 3 4	Isosceles right triangle, right angle at 3
2 3 4	Isosceles right triangle, right angle at 2
3 3 4	Equilateral triangle

consecutive points. We classify the 1-regions according to their end points: e.g., "1 2" refers to a 1-region with one end from Set 1 and the other from Set 2.

The plane of intersection of two or more cell-hyperplanes is covered by a network of lines of intersection. We wish to consider the minimal finite regions into which the plane is cut by this network (minimal in the sense that if P_1 and P_2 are distinct points in the interior of the same region, then the segment $\overline{P_1P_2}$ will not intersect a line of the network). These regions are the "2-regions" of Table III.

In Table IV, we do the same to a cell-hyperplane: we consider its decomposition by its intersections with the other cell-hyperplanes not parallel to it, and classify the minimal finite regions into seven categories.

Table V concerns itself with the division of E^4 by the cell-hyperplanes. The regions can be classified into five "layers," of which the innermost is the 16-cell itself.

The layers **b**, **c**, and **d** completely surround the origin; thus, for instance, in

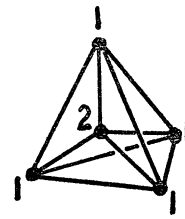
the solid obtained by uniting the 16-cell with layer **b**, no part of the 16-cell "remains visible." The layer **b** by itself is not a valid stellated form, by Miller's condition (iv). Thus, if layer **b** is to be present, layer **a** must also be present. Likewise, if layer **c** or **d** is present, then all layers interior to it must be present. Our procedure for naming the stellated forms thus obtained appears in Table VI.



Layer **e** is unique in that it is "center-exposing": there are "holes" in it through which the origin can be reached. Thus, layer **e** by itself constitutes a

valid stellated form; and by combining it with **D**, we obtain still another valid form.

The stellated form **A** is the 16-cell itself. **B** is the compound of two hypercubes, listed by Coxeter [2, p. 150] as $[2\gamma_4]\beta_4$. The vertices of this compound

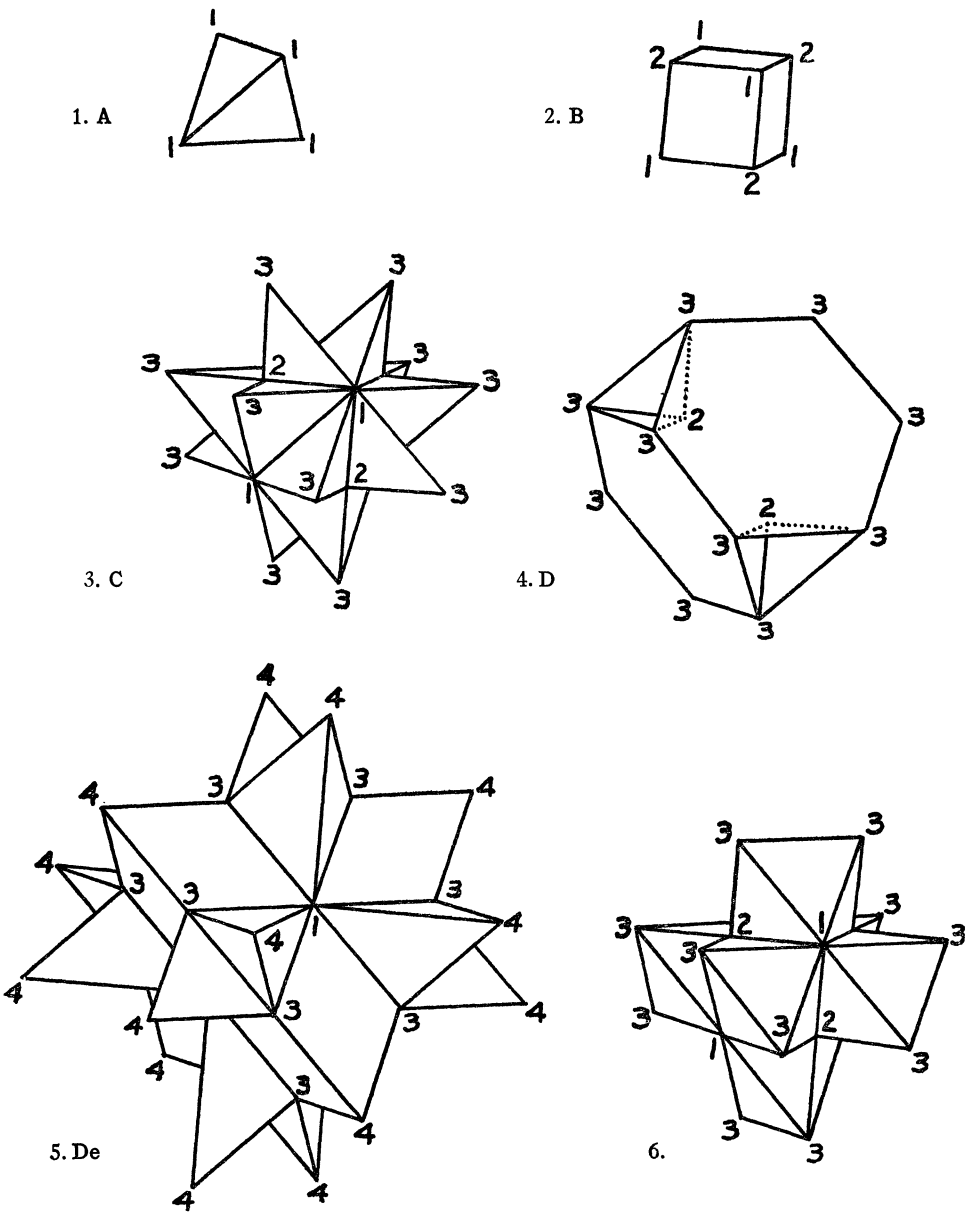

PLATE II. Cells of stellated forms.

(the vertices of our Set 1 and Set 2) are the vertices of a regular 24-cell, $\{3, 4, 3\}$, but 8 of these are shared by two hypercubes whereas the other 16 belong to only one hypercube. The "visible" portion of **B** consists of 64 tetrahedra 1 1 1 2. **C** is formed by inserting into the indentations between pairs of these the 32 figures **c**. This gives a polytope whose visible portions are 192 tetrahedra 1 1 2 3. Into the indentations between pairs of these will fit the 96 simplexes **d**, giving the polytope **D**. Two adjacent cells of **D** which fit together at one of the hexagonal faces are related by a turn through $\pi/3$ radians, so that the triangular depressions are not adjacent. The hexagonal faces are the equatorial hexagons of the cuboctahedra of the semi-regular polytope $\left\{\begin{smallmatrix}3,3\\4\end{smallmatrix}\right\}$.

Placed on **D**, the figures **e** leave the cells 1 1 3 3 of **D** exposed; hence the figures **e** by themselves leave the center of symmetry exposed.

Plate I illustrates the components of the five layers **a**, **b**, **c**, **d**, and **e**. The vertices are numbered according to the sets to which they belong. Plate II illustrates the cells of the stellated forms. The form **e** has "hollow" cells, each one like the solid of Figure II-5 with the solid of Figure II-6 removed.

ON THE THEORY OF PRE-p-RINGS

H. J. WEINERT, Teachers Training College, Potsdam, Germany

Let p be a prime. Generalizing the concept of p-rings, A. Abian and W. A. McWorter [1] call an associative and commutative ring R with characteristic p a pre-p-ring if $xy^p = x^p y$ for every x and y in R. They prove the following theorem: *Every pre-p-ring R is a direct sum $R = B \oplus N$ of a p-ring B and a nil ring N, where even $x^{p+2} = 0$ for every $x \in N$.* Of course, N is a pre-p-ring, too. It was proved in [1] that N is the radical of R and hence N is uniquely determined by R. Moreover, it is not difficult to show that B is also uniquely determined by R.

A simple calculation shows the following converse of this theorem: *The direct sum $R = B \oplus N$ of a p-ring B and a pre-p-nil-ring N is a pre-p-ring.* Since the structure of p-rings is known, there remains to investigate only the pre-p-nil-rings, which is the purpose of this paper.

First we determine the pre-p-nil-rings as certain algebras over the prime field F_p of characteristic p (Theorem 1). Many pre-p-nil-rings, among them those which may be generated by one element, arise as semigroup rings or as semi-

group rings with a factor system over F_p (cf. Theorem 2 and Theorem 3), but this is not true for all pre-p-nil-rings. In the second part we deal with subdirect decompositions of pre-p-nil-rings. We recall that every p-ring is a subdirect sum and in the finite case even a direct sum of prime fields F_p (cf. [4], [5]); in particular, every subdirectly irreducible p-ring is isomorphic to F_p. Just so every pre-p-nil-ring is a subdirect sum of subdirectly irreducible pre-p-nil-rings. But here we have for every characteristic p even an infinite number of subdirectly irreducible pre-p-nil-rings (likewise of finite as of infinite order), which are not isomorphic (Theorem 6). Another contrast to the situation with p-rings is the existence of finite pre-p-nil-rings, which are subdirectly reducible although they have no decomposition into a direct sum. Finally, for the subdirect irreducibility of a pre-p-nil-ring N it is necessary (Theorem 4) and in the finite case necessary and sufficient (Theorem 5), that the annihilator of N be a principal ideal different from (0).

1. By an algebra over F_p we mean in the following a ring R (for our purposes always associative and commutative), which is also a vector space over the prime field F_p of characteristic p. Hence every element of R may be written uniquely in the form

$$\sum_{i\in I} a_i w_i \quad a_i \in F_p, \text{ only a finite number } a_i \neq 0 \tag{1}$$

by the help of a basis $\{w_i\} \subseteq R$, where I is an index system of an arbitrary cardinal number.

THEOREM 1. *Let R be an algebra over F_p with a basis $\{w_i\}$ having the following properties:*

(a) *$w_i w_i^p = w_i^p w_j$ for every w_i and w_j.*

(b) *For every w_i there is a (minimal) natural number $t = t(w_i) \geqq 2$ with $w_i^t = 0$.*

Then R is a pre-p-nil-ring and, conversely, every pre-p-nil-ring N is an algebra of this kind.

We note that (a) and (b) imply $t(w_i) \leqq p+2$ for every w_i (cf. the proof of Lemma 1 in [1]), whereas conversely (a) is trivial if (b) always holds with $t(w_i) \leqq p$.

Proof. By well-known rules for characteristic p we have for arbitrary elements (1) of the algebra R

$$\left(\sum a_i w_i\right)^{p^2} = \sum a_i w_i^{p^2} = 0,$$

$$\left(\sum a_i w_i\right)\left(\sum b_j w_j\right)^p = \sum a_i b_j w_i w_j^p = \sum a_i b_j w_i^p w_j = \left(\sum a_i w_i\right)^p \left(\sum b_j w_j\right).$$

Hence R is a pre-p-nil-ring. Conversely, every pre-p-nil-ring N obviously is a unitary F_p-module and therefore a vector space over F_p with a basis $\{w_i\} \subseteq N$. Now, (a) and (b) are true even for all elements of N.

With the aid of this theorem many pre-p-nil-rings may easily be given. For example, one starts with a commutative semigroup $H=\{0, w_i\}$, $i\in I$ with zero 0, which satisfies (a) and (b), and takes $\{w_i\}=H\setminus\{0\}$ with the multiplication determined by H as basis of an algebra R over F_p. Such an algebra R is what we call here the *semigroup ring of H over F_p*. (More precisely, in a first step one has to take also $0\in H$ as a basis element of an algebra R^* over F_p, where $0\neq 0^*$ for the zero 0^* of R^*. The considered ring R then arises by "identifying" of these zeros, i.e. as residue class ring $R=R^*/(0-0^*)$ of R^* modulo the ideal $(0-0^*)$; cf. e.g. [6], Section 66.) If we choose

$$H = \{w, w^2, \cdots, w^{t-1}, w^t = w^{t+1} = \cdots = 0\}, \quad 2 \leqq t \leqq p+2, \tag{2}$$

i.e. the cyclic semigroup of order t and period 1 (cf. [2]), (a) and (b) hold and we have

THEOREM 2. *Every pre-p-nil-ring N, which is generated by one element, is a semigroup ring R of a cyclic semigroup H of period 1 and order t $(2\leqq t\leqq p+2)$ over F_p and conversely. Hence for a fixed characteristic p there exist exactly $p+1$ pre-p-nil-rings (up to isomorphisms), generated by one element.*

Proof. From the text above, it is clear that R is a pre-p-nil-ring, generated by the element w. Conversely, let w be a generating element of a pre-p-nil-ring N. Then all the powers of w form a subsemigroup (2) of N, and for the semigroup ring R of H over F_p we have $R\subseteq N$, from which by assumption $R=N$.

Let again $H=\{0, w_i\}$ be a (commutative) semigroup with zero 0. We say that R is a *semigroup ring of H over F_p with a factor system* $\{c_{w_i,w_j}\}$, if R is an algebra over F_p with the basis $\{w_i\}$, for which multiplication is defined by

$$w_i \circ w_j = c_{w_i,w_j} w_i w_j, \qquad c_{w_i,w_j} \in F_p. \tag{3}$$

(Here we have also identified the zeros as explained in the paragraph preceding Theorem 2. Hence the values of the factors c_{w_i,w_j} for $w_iw_j=0$ are irrelevant and may be chosen arbitrarily.)

It is known that R is associative if and only if (cf.e.g. [6])

$$c_{w_i,w_j} c_{w_iw_j,w_k} = c_{w_i,w_jw_k} c_{w_j,w_k} \quad \text{for } w_iw_jw_k \neq 0,$$

whereas commutativity is preserved if and only if

$$c_{w_i,w_j} = c_{w_j,w_i} \quad \text{for } w_iw_j \neq 0.$$

The special case $c_{w_i,w_j}=1\in F_p$ for every w_i, w_j corresponds to the semigroup ring in the above sense.

THEOREM 3. *Let $H=\{0, w_i\}$ be a commutative semigroup with zero 0, which satisfies* (a) *and* (b). *Then every semigroup ring R of H over F_p with a factor system $\{c_{w_i,w_j}\}$ is a pre-p-nil-ring, if $c_{w_i,w_i}\neq 0$ for $w_i^2\neq 0$.*

(This condition is superfluous if $t(w_i)\leqq p$ for every $w_i\in H$. On the other hand, it means no loss of generality, because all semigroup rings with factor sys-

tems (yet even all monomial algebras, cf. [7], Section 4) are included, if one only considers factor systems with $c_{w_i,w_j}=0 \Leftrightarrow w_iw_j=0$.)

Proof. From $w_i^t=0$ it follows immediately that

$$\underbrace{w_i \circ \cdots \circ w_i}_{t} = c_{w_i,w_i}^{t-1} w_i^t = 0.$$

Moreover, the property (a) of the multiplication $\cdot$ of the w_i carries over to the multiplication $\circ$ according to

$$w_i \circ \underbrace{w_j \circ \cdots \circ w_j}_{p} = c_{w_i,w_j} c_{w_j,w_j}^{p-1} w_i w_j^p = c_{w_i,w_j} c_{w_i,w_i}^{p-1} w_i^p w_j = \underbrace{w_i \circ \cdots \circ w_i}_{p} \circ w_j.$$

This is not trivial only in the case $w_iw_j^p=w_i^pw_j\neq 0$ and $c_{w_i,w_j}\neq 0$. But then, by assumption, $c_{w_i,w_i}\neq 0$ and $c_{w_j,w_j}\neq 0$; hence the $(p-1)$-th powers of these factors are equal to $1\in F_p$. Therefore R is a pre-p-nil-ring by Theorem 1.

We note at once that not all pre-p-nil-rings, not even those which are finite or subdirectly irreducible (cf. Section 2), arise as semigroup rings with a factor system according to Theorem 3 (hence also not as monomial algebras, cf. [7]). We restrict ourselves to a simple counter-example for characteristic $p=2$ and consider the algebra $N=R$ over F_2 with the basis $\{u, u^2, v, v^2, q\}$ and the multiplication table

	u	u^2	v	v^2	q
u	u^2	0	u^2+v^2	q	0
u^2	0	0	q	0	0
v	u^2+v^2	q	v^2	0	0
v^2	q	0	0	0	0
q	0	0	0	0	0

It is easy to see that by Theorem 1 R is a pre-2-nil-ring. But it is impossible to choose a basis $\{w_1, \cdots, w_5\}\subseteq R$ in such a way that for every w_i, w_j the product w_iw_j is a multiple of one of the elements of this basis (i.e. here of course equal to zero or to the basis element itself, since we have F_2 as operator domain). In order to prove this assertion, we observe first that in each basis there must be two elements w_1 and w_2 such that the terms u or $u+v$ occur in w_1 and v or $u+v$ occur in w_2 (and of course not $u+v$ in both). Then we get from

$$w_1^2,\ w_2^2,\ w_1w_2,\ w_1w_2^2 = w_1^2w_2$$

up to the order of succession the four linearly dependent elements u^2 or u^2+q, v^2 or v^2+q, u^2+v^2 or u^2+v^2+q, q, which can not be obtained in the basis $\{w_i\}$.

2. The considerations of this section concerning the decomposition of pre-p-nil-rings as subdirect sums (for the concepts and properties of subdirect sums, used in the following, cf. e.g. [4]) are based on the following

PROPOSITION. *Every pre-p-nil-ring N is isomorphic to a subdirect sum of subdirectly irreducible pre-p-nil-rings N_i, and conversely every subdirect sum of pre-p-nil-rings is again a pre-p-nil-ring.*

The first part is an immediate consequence of the fact that a homomorphic image of a pre-p-nil-ring is also one. For the second, it suffices to show that the direct sum of pre-p-nil-rings N_i is also a pre-p-nil-ring, which follows essentially from $x_i^{p+2}=0$ for every x_i of each pre-p-nil-ring N_i.

Therefore our main interest is the study of subdirectly irreducible pre-p-nil-rings. As already mentioned in the introduction, the situation is here much more complicated than for p-rings, but, some information is given in what follows, where the annihilator Q of N, i.e. the ideal of all elements $q\in N$ with $qx=0$ for every $x\in N$, is of some importance.

THEOREM 4. *Every subdirectly irreducible pre-p-nil-ring N has an annihilator $Q\neq(0)$, which is a principal ideal of N and hence it consists of exactly p elements $q, 2q, \cdots, pq=0$.*

This assertion is even true for nilpotent rings with characteristic p and is a special case of Theorem 2 of [3].

We give first an example of a pre-p-nil-ring without an annihilator ($\neq 0$), which is then subdirectly reducible by Theorem 4. Let H be the commutative semigroup with zero 0, generated by the (countable) infinite set of elements $u_1, u_2, \cdots$, with the defining relations

$$u_i^2 = 0 \quad \text{for every } i.$$

Then every nonzero element of H has a unique representation

$$u_{k_1}u_{k_2}\cdots u_{k_m} \quad \text{with} \quad k_1 < k_2 < \cdots < k_m. \tag{4}$$

Now we regard the semigroup ring N of H over F_p (with arbitrary characteristic p), which is according to section 1 a pre-p-nil-ring. This ring N has only the zero as annihilator, hence it is a ring of the desired kind. Indeed, every element $x\neq 0$ of N is a linear combination of a finite number of elements (4), and we have $xu_j\neq 0$ for every j greater than all the indices k_m of the factors u_{k_m} which occur in the terms of x.

By the help of this example, we see that the converse of Theorem 4 is false. For this purpose we take the direct sum $N\oplus Q$ of N with a zero-ring Q of p elements. Then $N\oplus Q$ is a pre-p-nil-ring with the principal ideal $Q\neq(0)$ as annihilator, though it is subdirectly reducible. But we have

THEOREM 5. *A finite pre-p-nil-ring N always has an annihilator $Q\neq(0)$ and it is subdirectly irreducible if and only if Q is a principal ideal.*

Proof. For the first assertion we take an arbitrary element $x_1\neq 0$ of N. Either we have $x_1x_2\neq 0$ for every $x_2\in N$, or there is an element $x_2\in N$ with $x_1x_2\neq 0$. In the same manner we regard $(x_1x_2)x_3$ and so on. Since N is finite and every

element of N is nilpotent, we obtain in this way an annihilator element $q = x_1x_2 \cdot \cdot \cdot x_n \neq 0$. Hence $Q \neq (0)$. Moreover, it follows from this consideration, that every ideal $A \neq (0)$ of N contains at least one annihilator element $q \neq 0$.

Now let Q be a principal ideal. Then we have $Q = (q)$ for every nonzero $q \in Q$. Therefore the intersection of all ideals $A \neq (0)$ of N contains Q and hence N is subdirectly irreducible. If the latter is true, then Q is a principal ideal by Theorem 4.

COROLLARY. *Every pre-p-nil-ring N, generated by one element w, is subdirectly irreducible.*

Proof. According to Theorem 2, N is the semigroup ring of the semigroup $\{w, w^2, \cdot \cdot \cdot, w^{t(w)-1}\}$ and the annihilator of N is the principal ideal $Q = (w^{t(w)-1})$.

We note in this connection, that subrings of such a pre-p-nil-ring N throughout may be subdirectly reducible. For example, suppose that $t(w) \geqq 4$, and let U be the subring of N which is generated by the elements $w^2, \cdot \cdot \cdot, w^{t(w)-1}$. Then $w^{t(w)-2} \neq 0$ and $w^{t(w)-1} \neq 0$ are elements of the annihilator Q of U, which is therefore not a principal ideal. Hence U is subdirectly reducible by Theorem 5. Contrasting the situation with finite p-rings (cf. the introduction), U is not directly reducible if $t(w) \geqq 6$. In order to prove this, let us assume that $U = U_1 \oplus U_2$. Then at least in one of the U_i, say in U_1, there must occur an element $x = cw^2 + \cdot \cdot \cdot$ with $cw^2 \neq 0$, perhaps among other terms. Suitable multiplications with w^2 and w^3 show that $cw^{t(w)-1} \in U_1$, then $cw^{t(w)-2} \in U_1$ and therefore $Q \subseteq U_1$. As we must have $Q \cap U_2 \neq (0)$ (cf. the proof of Theorem 5), this contradicts $U_1 \cap U_2 = (0)$.

Moreover, besides the pre-p-nil-rings generated by one element, there are many others, which are likewise subdirectly irreducible (for example, the ring presented at the end of Section 1 with the annihilator $Q = (q)$, or those subrings of the pre-p-nil-ring N without annihilator constructed after Theorem 4, which are generated by the elements $u_1, \cdot \cdot \cdot, u_k$). In this respect we have even the following

THEOREM 6. *For every characteristic p there is an infinite number of (not isomorphic) subdirectly irreducible pre-p-nil-rings which have* (i) *a finite,* (ii) *an infinite order.*

Proof. In order to construct such rings we take an index system I of an arbitrary cardinal number. Let H be the commutative semigroup with zero 0, which is generated by the elements u_i $(i \in I)$, v_i $(i \in I)$ and q with the defining relations

$$\left.\begin{aligned} u_iu_j &= 0 \\ v_iv_j &= 0 \end{aligned}\right\} \text{ for every } i \in I, j \in I;$$

$$u_iv_j = 0 \quad \text{for every } i \in I, j \in I \text{ with } i \neq j;$$

$$u_iv_i = q \quad \text{for every } i \in I.$$

From these it follows that $qu_i = qv_i = q^2 = 0$. Then H consists exactly of the ele-

ments $0, u_i, v_i, q$, and the semigroup ring N of H over F_p is a pre-p-nil-ring according to section 1. Moreover, $Q=(q)$ is just the annihilator of N, and we have $q\in A$ for every ideal $A\neq(0)$ of N. Hence N is subdirectly irreducible. If the index systems I and I' have different cardinal numbers, the same is true for the corresponding pre-p-nil-rings N and N', from which our theorem follows.

HYPERSPHERES ASSOCIATED WITH AN n-SIMPLEX

H. E. VAUGHAN and HYMAN GABAI, University of Illinois

1. Introduction. Suppose that A_0 and A_1 are two points of an oriented line. For any point P of this line, let V, V_0, and V_1 be the directed distances from A_0 to A_1, from P to A_1, and from A_0 to P, respectively. Then $V_0+V_1=V$. It is well known that if $\boldsymbol{a}_0$, $\boldsymbol{a}_1$, and $\boldsymbol{p}$ are the position vectors of A_0, A_1, and P, respectively, with respect to any origin O, then

$$\boldsymbol{p}=\boldsymbol{a}_0\frac{V_0}{V}+\boldsymbol{a}_1\frac{V_1}{V}. \tag{1}$$

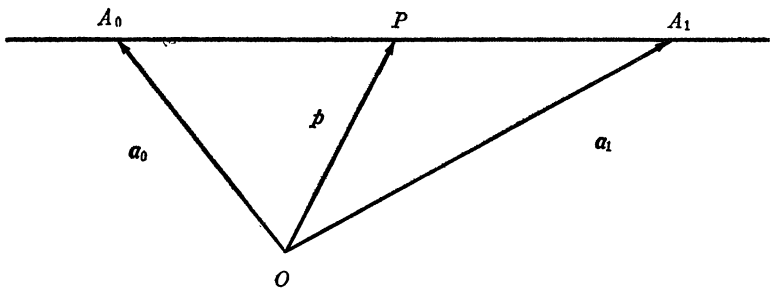

FIG. 1

In another notation which we shall sometimes use:

$$P - O = (A_0 - O)\frac{V_0}{V} + (A_1 - O)\frac{V_1}{V}.$$

(This notation is introduced in [1]. Translations of Euclidean space are elements of a vector space of the same dimension. Using the notation in question, $Y-X$ is the translation which maps X onto Y, and the image of a point Z under this mapping is $Z+(Y-X)$.)

In this paper we generalize this result and obtain information concerning some hyperspheres associated with an n-simplex.

As an indication of how (1) can be generalized, note that the numbers V, V_0, and V_1 can be described as the sensed length-measures of the oriented 1-simplexes A_0A_1, PA_1, and A_0P. (Since P may be A_0 or A_1, the second or third of these simplexes may be degenerate.) In order to speak of sensed length-measures (or equivalently, of directed distances) the line containing A_0 and A_1 must be oriented. But, since such measures enter into (1) only as ratios, which orientation one chooses is immaterial as far as (1) is concerned. It will be convenient, however, to assume that the orientation of the line is that determined by the oriented simplex A_0A_1 (equivalently, that the chosen positive direction is from A_0 to A_1). With this choice, $V>0$.

2. The position vector of a point in n-space. Now, suppose that $A_0 \ldots A_n$ is an oriented nondegenerate n-simplex σ. Without loss of generality we assume that the n-space containing σ is oriented so that the sensed (n-dimensional) measure V of σ is positive. Let P be any point of this n-space and, for $0 \leqq i \leqq n$, let σ_i be the oriented (possibly degenerate) n-simplex obtained from σ by replacing A_i by P. More precisely, σ_i is the image of σ under the linear mapping which, for $j \neq i$, leaves A_j fixed and which maps A_i onto P. Let V_i be the sensed measure of σ_i. Then $\sum_{i=0}^{n} V_i = V$. (See, for example, [2], page 234.) Let $\boldsymbol{a}_0, \cdots, \boldsymbol{a}_n$, and $\boldsymbol{p}$ be position vectors of $A_0, \cdots, A_n$ and P respectively with respect to any origin O. Then,

THEOREM 1. $\boldsymbol{p} = \sum_{j=0}^{n} \boldsymbol{a}_j (V_j/V)$.

Proof. For $1 \leqq j \leqq n$, let $\boldsymbol{b}_j = A_j - A_0 = \boldsymbol{a}_j - \boldsymbol{a}_0$, and let $\boldsymbol{r} = P - A_0 = \boldsymbol{p} - \boldsymbol{a}_0$. Since P belongs to the space spanned by $(\boldsymbol{b}_1, \cdots, \boldsymbol{b}_n)$ there are numbers $x_1, \cdots, x_n$ such that $\boldsymbol{r} = \sum_{j=1}^{n} \boldsymbol{b}_j x_j$. The linear transformation previously described which maps σ on σ_i has, with respect to the basis $(\boldsymbol{b}_1, \cdots, \boldsymbol{b}_n)$, the matrix which differs from the identity only in having $(x_1, \cdots, x_n)$ as its ith row. Hence, the determinant of this transformation is x_i. Consequently, $V_i = Vx_i$ (see, for example, [2], page 300) and

$$\boldsymbol{p} - \boldsymbol{a}_0 = \boldsymbol{r} = \sum_{j=1}^{n} (\boldsymbol{a}_j - \boldsymbol{a}_0)\frac{V_j}{V}.$$

The theorem follows at once on noting that $1 - \sum_{j=1}^{n} (V_j/V) = V_0/V$. (That

$V_i = Vx_i$ can be seen without using determinants. Let s_i be the $(n-1)$-measure of the face of σ opposite A_i and let h_i be the altitude of σ from A_i. Then ([3], p. 123), $V = h_i s_i/n$. The altitude of s_i from P is $h_i|x_i|$, and x_i is positive or negative according as P and A_i are on the same or opposite sides of the hyperplane containing the face of σ opposite A_i. It follows that $V_i = (h_i x_i)s_i/n$. Hence, $V_i = Vx_i$.)

Note that Theorem 1 provides an interpretation of the barycentric coordinates of P with respect to $A, \cdots, A_n$. In this form, these coordinates are obtained in [3] and, for the 2-dimensional case, in [4]. It still seems appropriate to include the proof given here since it makes use of the ideas of linear algebra which are basic for the rest of this paper.

It is interesting to consider some 2-dimensional applications of Theorem 1. If P is the centroid of $\triangle A_0A_1A_2$, it is well known that $\triangle PA_1A_2$, $\triangle A_0PA_2$, and

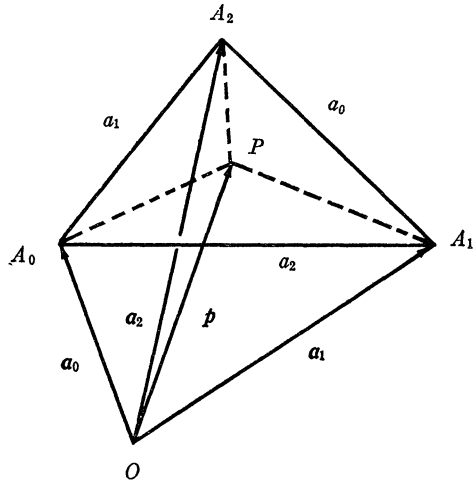

FIG. 2

$\triangle A_0A_1P$ (that is, σ_0, σ_1, and σ_2) all have the same area, and this is one-third the area of $\triangle A_0A_1A_2$. Consequently, $V_0/V = V_1/V = V_2/V = \frac{1}{3}$ and, by Theorem 1, we have the familiar formula:

$$p = \frac{a_0 + a_1 + a_2}{3}$$

for the position vector of the centroid.

If P is the incenter of $\triangle A_0A_1A_2$ then the triangles σ_0, σ_1, and σ_2 have the same altitude. Hence, their areas are proportional to the measures of the sides A_1A_2, A_2A_0, and A_0A_1. Taking these measures to be a_0, a_1, and a_2, we see from Theorem 1 that the position vector of the incenter is given by:

$$p = \frac{a_0a_0 + a_1a_1 + a_2a_2}{a_0 + a_1 + a_2}.$$

If P is the circumcenter of $\triangle A_0A_1A_2$ it is not hard to show that the sensed area-measure of σ_i is $(a_iR \cos \angle A_i)/2$, where R is the radius of the circumcircle. So, by Theorem 1, the position vector of the circumcenter is given by:

$$\boldsymbol{p} = \frac{\boldsymbol{a}_0(a_0 \cos \angle A_0) + \boldsymbol{a}_1(a_1 \cos \angle A_1) + \boldsymbol{a}_2(a_2 \cos \angle A_2)}{a_0 \cos \angle A_0 + a_1 \cos \angle A_1 + a_2 \cos \angle A_2}.$$

Returning for a moment to the proof of Theorem 1, we note that the numbers $x_1, \cdots, x_n$ are determined uniquely by P (and the points $A_0, \cdots, A_n$), and that, conversely, an arbitrary choice of these numbers determines a unique point P. Hence:

COROLLARY 1. *If* $\boldsymbol{p} = \sum_{j=0}^{n} \boldsymbol{a}_j y_j$ *and* $\sum_{j=0}^{n} y_j = 1$ *then, for* $0 \leqq j \leqq n$, $y_j = V_j/V$.

COROLLARY 2. *If* $\sum_{j=0}^{n} y_j = 1$ *then there is a point* P *such that, for* $0 \leqq j \leqq n$, $V_j = Vy_j$.

For example (reversing an earlier argument), it follows from Corollary 1, and the well-known formula for the position vector of the centroid P of an n-simplex σ, that each of the $n+1$ n-simplexes which has for its vertices P and the vertices of a face of σ has for its measure $V/(n+1)$, where V is the volume of σ. As a further consequence, the distance of P from a face of σ is $nV/(n+1)a_i$, where a_i is the measure of the face.

3. Hyperspheres tangent to $n+1$ hyperplanes. Theorem 1 and Corollary 1 give us a way of finding the hyperspheres each of which is tangent to the $n+1$ hyperplanes which contain the faces of an n-simplex. (In the case $n=2$, these are the inscribed circle and the three escribed circles of a triangle.) For $0 \leqq j \leqq n$, let π_j be the hyperplane which contains the face of σ opposite A_j, and let a_j be the measure of this face. Then,

COROLLARY 3. *Let* P *be the center of a hypersphere which, for* $0 \leqq j \leqq n$, *is tangent to* π_j, *and let* ϵ_j *be* 1 *or* -1 *according as* P *and* A_j *are on the same or opposite sides of* π_j. *Then* $\sum_{j=0}^{n} \epsilon_j a_j > 0$ *and the position vector of* P *is given by*:

$$\boldsymbol{p} = \sum_{j=0}^{n} \boldsymbol{a}_j(\epsilon_j a_j) \Big/ \sum_{j=0}^{n} \epsilon_j a_j. \tag{2}$$

Conversely, for any choice of the ϵ_j*'s such that each is* 1 *or* -1 *and* $\sum_{j=0}^{n} \epsilon_j a_j > 0$, *the point whose position vector is given by* (2) *is equidistant from all of the* π_j's.

Proof: Suppose that h is the radius of the hypersphere in question. Then, for $0 \leqq j \leqq n$, $V_j = (h_j \epsilon_j a_j)/n$, and $V = (1/n)h \sum_{j=0}^{n} \epsilon_j a_j > 0$. Hence, (2) follows from Theorem 1, and the remainder of the corollary follows from Corollary 1. Note that the radius h of the hypersphere is given by:

$$h = nV \Big/ \sum_{j=0}^{n} \epsilon_j a_j.$$

As an application of Corollary 3, the position vectors of the three escribed circles of a triangle of side measures a_0, a_1, and a_2, are (in terms of the position vectors of its vertices)

$$\frac{-a_0a_0+a_1a_1+a_2a_2}{-a_0+a_1+a_2},\qquad \frac{a_0a_0-a_1a_1+a_2a_2}{a_0-a_1+a_2},\quad\text{and}\quad \frac{a_0a_0+a_1a_1-a_2a_2}{a_0+a_1-a_2}.$$

As another application, we see that each n-simplex has an inscribed hypersphere the position vector of whose center is

$$\sum_{j=1}^{n} a_ja_j \Big/ \sum_{j=1}^{n} a_j,$$

when $a_0, \cdots, a_n$ are the position vectors of its vertices and $a_0, \cdots, a_n$ are the measures of the faces opposite these vertices. It follows that the incenter and the centroid of a simplex coincide if and only if all faces of the simplex have the same measure. (In particular, the incenter and centroid of a triangle coincide if and only if the triangle is equilateral.)

Since the measure of any face of an n-simplex is less than the sum of the measures of the other faces, we can choose in Corollary 3, any one of the ϵ_j's to be -1 and the remainder to be 1. So, in addition to an inscribed hypersphere, each n-simplex has $n+1$ "escribed" hyperspheres—that is, hyperspheres each of which is tangent to just one face of the simplex as well as being tangent to the planes which contain the remaining faces. It may (and, for $n>3$, it will) be possible to choose two or more of the numbers ϵ_j of Corollary 3 to be -1. For each such choice there will be a hypersphere which is tangent to each of the planes π_j but is not tangent to any face of the simplex. The case $n=3$—that of a tetrahedron—is interesting, partly because it is comparatively easy to analyze. In this case, in addition to the inscribed sphere and the four escribed spheres, there may be tangent spheres whose centers belong to one or another of the six wedge-shaped regions each of which has an edge of the tetrahedron on its boundary. Such a sphere is determined by choosing two of the numbers $\epsilon_0, \cdots, \epsilon_3$ to be -1 and two to be 1. It follows that a wedge will contain the center of a tangent sphere if and only if the sum of the area-measures of the two faces which intersect in the edge which is on the boundary of the wedge is less than the sum of the areas of the other two faces. (So, the wedges corresponding to two opposite edges cannot both contain centers of tangent spheres; and none of the wedges in the complement of a tetrahedron whose faces all have the same area can contain the center of a tangent sphere.) For a more complete analysis, suppose that the area-measures of the faces of a tetrahedron are such that $a_0 \leqq a_1 \leqq a_2 \leqq a_3$. In this case there will be a sphere corresponding to the choice

(a) $\epsilon_0=\epsilon_1=-1$ and $\epsilon_2=\epsilon_3=1$ if and only if $a_0+a_1<a_2+a_3$,

one corresponding to the choice

(b) $\epsilon_0=\epsilon_2=-1$ and $\epsilon_1=\epsilon_3=1$ if and only if $a_0+a_2<a_1+a_3$,

and one corresponding to one of the choices

(c) $\epsilon_0=\epsilon_3=-1$ and $\epsilon_1=\epsilon_2=1$, or $\epsilon_0=\epsilon_3=1$ and $\epsilon_1=\epsilon_2=-1$ if and only if $a_0+a_3\neq a_1+a_2$.

Notice that if $a_0+a_2<a_1+a_3$ then $a_0+a_1<a_2+a_3$, and that if $a_0+a_3\neq a_1+a_2$ then $a_0+a_2<a_1+a_3$. Hence, for a given tetrahedron, there may be only the inscribed and the four escribed spheres, or there may be, in addition the sphere obtained by the choice (a), or the two spheres obtained by the choices (a) and (b), or the three spheres obtained from the choices (a), (b), and (c). (These results are obtained in another way in [5], page 87.)

Considerations, similar to the preceding, show that there are at least 12 hyperspheres each of which is tangent to all of the five hyperplanes containing the faces of a nondegenerate 4-simplex. As is easily seen, this minimum is attained in the case of a 4-simplex whose faces have measures proportional to 1, 1, 1, 1, and 2. As follows from Corollary 3, there can be at most 16 hyperspheres tangent to all five hyperplanes. This maximum is attained in the case of a 4-simplex all of whose faces have the same measure.

In the general case it follows from Corollary 3 that there are at most 2^n hyperspheres each of which is tangent to all of the $n+1$ hyperplanes containing the faces of a nondegenerate n-simplex. For $n>1$ this maximum number is attained in the case of an n-simplex all but one of whose faces have the same measure, the remaining face having a measure $n-1$ times as great as the others. (For even n, the maximum is also attained by n-simplexes all of whose faces have the same measure.) The minimum number of such hyperspheres seems more difficult to determine. For n odd, consideration of simplexes all of whose faces have the same measure shows that the minimum is at most

$$2^n-\binom{n+1}{(n+1)/2}\Big/2.$$

For n even (and at least 4), considerations of simplexes all but one of whose faces have the same measure, that of the remaining face being twice as great, shows that the minimum is at most

$$2^n-\binom{n}{(n+2)/2}.$$

The use of these formulas together with some hack-work shows that, for $n=5$, the minimum is 22, and that, for $n=6$, the minimum is at least 36 and at most 49.

4. The circumscribed hypersphere. We have given earlier a formula for the position vector of the center of the circumcircle of a triangle (and have suggested a derivation of it based on Theorem 1). We shall now use a different approach to find the position vector of the center of the hypersphere circumscribed about an n-simplex (see the corollary to Theorem 2, below) and apply Theorem 1 to interpret the result. To begin with, we obtain an equation for the hypersphere in question. As previously, $A_0, \cdots, A_n$ is a nondegenerate n-simplex σ and, as in the proof of Theorem 1, for $1\leqq j\leqq n$, $\boldsymbol{b}_j=A_j-A_0$.

THEOREM 2. *Let S be the hypersphere which contains the vertices of σ. Then, a point X belongs to S if and only if*

$$X - A_0 = \sum_{j=1}^{n} b_j x_j, \tag{3}$$

where the numbers $x_1, \cdots, x_n$ satisfy the equation

$$\left(\sum_{j=1}^{n} b_j x_j \right)^2 = \sum_{j=1}^{n} b_j^2 x_j. \tag{4}$$

Moreover, the radius R of the hypersphere S is given by

$$R^2 = \sum_{j=1}^{n} b_j^2 \frac{V_j}{2V}, \tag{5}$$

where the volumes V_j are the volumes described in the beginning of section 2.

Proof. Let P be the center of S and let $\mathbf{r} = P - A_0$. Since, for $1 \leqq j \leqq n$, the radius of S which is perpendicular to the chord A_0A_j bisects this chord, it follows that

$$\mathbf{b}_j \cdot \mathbf{r} = b_j^2/2 \qquad (1 \leqq j \leqq n). \tag{6}$$

Now, $X \in S$ if and only if $\|X-P\| = \|P-A_0\|$. Since $X-P = (X-A_0) + (A_0-P) = (X-A_0) - \mathbf{r}$ it follows that $X \in S$ if and only if

$$\|(X - A_0) - \mathbf{r}\| = \|\mathbf{r}\|. \tag{7}$$

By (3), (7) is equivalent to:

$$\left(\sum_{j=1}^{n} b_j x_j - \mathbf{r} \right)^2 = \mathbf{r}^2.$$

Since, by (6),

$$\left(\sum_{j=1}^{n} b_j x_j - \mathbf{r} \right)^2 = \left(\sum_{j=1}^{n} b_j x_j \right)^2 - \sum_{j=1}^{n} b_j^2 x_j + \mathbf{r}^2,$$

(7) is equivalent to (4).

(Notice that in case $n=2$ and $\mathbf{b}_1$ and $\mathbf{b}_2$ are orthogonal, (4) reduces to the polar equation: $r^2 = b_1 r \cos\theta + b_2 r \sin\theta$ of the circle which passes through the pole A_0 of a polar coordinate system and the points A_1 and A_2 with polar coordinates (b_1, θ) and $(b_2, \pi/2)$, respectively; $(b_i = \|\mathbf{b}_i\|)$.)

The position vector $\mathbf{r}$, with respect to A_0, of the center P of S can be found in terms of the basis $(\mathbf{b}_1, \cdots, \mathbf{b}_n)$ by solving the equations (6). Assuming that $\mathbf{r} = \sum_{j=1}^{n} \mathbf{b}_j y_j$, we find, from (6), that

$$\sum_{j=1}^{n} (\mathbf{b}_i \cdot \mathbf{b}_j) y_j = b_i^2/2 \qquad (1 \leqq i \leqq n).$$

So, by Cramer's rule, $y_j = G_j/G$, $(1 \leqq j \leqq n)$ where G is the Gram determinant of $(\boldsymbol{b}_1, \cdots, \boldsymbol{b}_n)$ and G_j is obtained from G by replacing the entry in its ith row and jth column (j fixed, $1 \leqq i \leqq n$) by $b_i^2/2$. Hence,

$$\boldsymbol{r} = \sum_{j=1}^{n} \boldsymbol{b}_j \frac{G_j}{G} \cdot \tag{8}$$

As in the proof of Theorem 1, if, with respect to some arbitrary origin O, the position vectors of $A_0, \cdots, A_n$, and P are $\boldsymbol{a}_0, \cdots, \boldsymbol{a}_n$, and $\boldsymbol{p}$, respectively, then $\boldsymbol{r} = \boldsymbol{p} - \boldsymbol{a}_0$ and, for $1 \leqq j \leqq n$, $\boldsymbol{b}_j = \boldsymbol{a}_j - \boldsymbol{a}_0$. Substituting in (8) we obtain

$$\boldsymbol{p} = \sum_{j=0}^{n} \boldsymbol{a}_j \frac{G_j}{G},$$

where, for $1 \leqq j \leqq n$, G_j is as described above and $G_0 = G - \sum_{j=1}^{n} G_j$.

Since $\sum_{j=0}^{n} G_j/G = 1$ it follows from Corollary 1 to Theorem 1 that, for $0 \leqq j \leqq n$, $G_j/G = V_j/V$. Since it is a property of the Gram determinant G that

$$V = \frac{1}{n!}\sqrt{G},$$

(see, for example, [6], page 170) it follows that $V_j = (1/n!)(G_j/\sqrt{G})$, $(0 \leqq j \leqq n)$.

The radius R of the hypersphere S is easily computed in terms of the lengths of the sides of σ issuing from A_0 and the sensed measures of σ and σ_j, $1 \leqq j \leqq n$. To do so, note that, since $P = A_0 + \boldsymbol{r}$, $A_0 + \boldsymbol{r} 2 \in S$. Since

$$\boldsymbol{r}^2 = \sum_{j=1}^{n} \boldsymbol{b}_j \frac{2G_j}{G}$$

it follows that

$$R^2 = \|\boldsymbol{r}\|^2 = \frac{1}{4}\left(\sum_{j=1}^{n} \boldsymbol{b}_j \frac{2V_j}{V}\right)^2$$

$$= \frac{1}{4}\sum_{j=1}^{n} b_j^2 \frac{2V_j}{V} = \sum_{j=1}^{n} b_j^2 \frac{V_j}{2V} \cdot$$

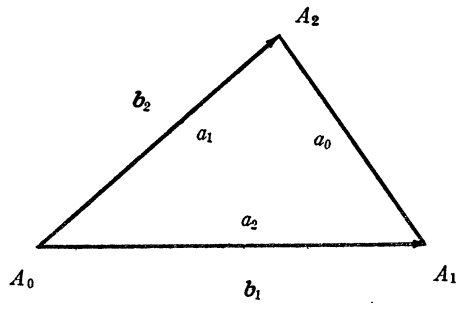

FIG. 3

This proves (5).

Finally, let us consider the 2-dimensional case. In this case

$$G = \begin{vmatrix} b_1^2 & b_1 \cdot b_2 \\ b_1 \cdot b_2 & b_2^2 \end{vmatrix}, \quad \text{and} \quad G_1 = \frac{1}{2} \begin{vmatrix} b_1^2 & b_1 \cdot b_2 \\ b_2^2 & b_2^2 \end{vmatrix}.$$

Since $b_1^2 = a_2^2$, $b_2^2 = a_1^2$, and $b_1 \cdot b_2 = a_1 a_2 \cos \angle A_0$ it follows that

$$G = a_1^2 a_2^2 (1 - \cos^2 \angle A_0) = a_1^2 a_2^2 \sin^2 \angle A_0$$

and

$$2G_1 = a_1^2 (a_2^2 - a_2 a_1 \cos \angle A_0) = a_1^2 a_2 (a_2 - a_1 \cos \angle A_0) = a_1^2 a_2 a_0 \cos \angle A_1.$$

Hence,

$$V_1 = \frac{G_1}{2\sqrt{G}} = \frac{a_1 a_0 \cos \angle A_1}{4 \sin \angle A_0} = \frac{a_1 R \cos \angle A_1}{2} \left(= \frac{a_1^2 \cot \angle A_1}{4} \right).$$

By symmetry, similar formulas hold for V_2 and V_0. (As noted previously, these formulas can also be obtained by more elementary methods.) They yield formulas for the distance between the circumcenter and the sides and, by summation, formulas for the area of the triangle.

SOME RESULTS IN VECTOR POTENTIAL THEORY

J. M. DOYLE, University of Illinois, Chicago

1. Introduction. Traditionally, the development of methods of formal solution for the displacement equilibrium equations of classical elasticity has paralleled work done in connection with the solution of Laplace's equation. This is perhaps to be expected inasmuch as this set of equations represents a generalization of second order, elliptic differential operators to vector functions. Beginning

with the work of Betti [1] in 1872 and continuing for the next forty years or so, the Italian geometers produced an extensive volume of literature dealing with the adaptation of potential theory methods to the theory of elasticity. In 1895, Lauricella [2] noting that solutions to the field equations can be constructed which are analogous to potentials of single and double layer distributions, demonstrated that the discontinuities encountered by the functions or their associated stress vectors are similar to those of harmonic functions or their normal derivatives in ordinary potential theory.

It is the purpose of this paper to outline a modern, concise and hopefully, a clearer treatment of the work just mentioned and at the same time to extend the ideas to the time-independent equations of classical elastokinetics. Throughout, the results from ordinary potential theory, as set forth by O. D. Kellogg [3], are utilized whenever applicable. Where such results cannot be utilized directly, slight modifications of the procedures employed by Kellogg can be used to carry out the various limit processes. For the sake of brevity and in order not to bore the reader with a great deal of computational detail, only end results have been included here. Solutions are constructed by integration over volume or surface of the inner product of a vector density and a singular dyadic which is, except at the singular point, a solution to the basic differential equation. These singular dyadics are akin to the function e^{ikr}/r or its normal derivative as singularities for the Helmholtz equation. Following the previous work, two different surface potentials are defined; one which is similar to a single layer and the other resembling a double layer. In each case the function and its derivatives are examined as the point at which they are evaluated approaches the surface along a normal. Not unexpectedly, the behavior of the function and the associated stress vector are the same as for their counterparts in the scalar case. That is, the vector itself is continuous across the surface for the single layer type while its stress vector is not and so on.

Aside from their significance from the theoretical point of view, it is possible that the results established here can be utilized in formulating certain boundary value problems in elastic body motion. This, of course, includes static problems as a special case.

II. Preliminary Information.

1. *Notation and Definitions.* Throughout this paper, the conventional vector and dyadic notation is employed. Vectors are shown as typed letters with a bar above and dyadics are symbolized by typed letters with a double bar above. The dot and cross placed between two vectors indicate scalar or vector multiplication respectively. The symbol ∇ represents the standard del operator. Operations on dyadics with this operator follow the convention of Weatherburn [4].

Regular regions and regular surfaces are defined according to Kellogg [3]. In general D represents a regular open region, B its bounding surface, and $D+B$ the closed region.

2. *Basic Equations and Identities.* The basic differential equation with which we are here concerned is

$$\bar{\bar{C}}\cdot\bar{u} + k^2\bar{u} = (b^2 - a^2)\nabla\nabla\cdot\bar{u} + a^2\nabla^2\bar{u} + k^2\bar{u} = 0, \tag{2.1}$$

where a and b represent the propagation speeds of shear and dilatational waves. This equation is understood to hold for all points in a region D. Two common types of boundary conditions which are of interest are: (1) specification of the vector $\bar{u}$ at each point of the surface B, and (2) specification of the surface stress vector at points of B. The surface stress vector is given by

$$\bar{T}(\bar{u}) = \rho\left[2a^2\frac{d\bar{u}}{dn} + (b^2 - 2a^2)(\nabla\cdot\bar{u})\bar{n} + a^2\bar{n}\times\nabla\times\bar{u}\right], \tag{2.2}$$

where $\bar{n}$ is the unit outward normal on B and ρ is the mass density of the material.

For two vectors $\bar{u}$ and $\bar{v}$ which, along with their first derivatives, are continuous in $D+B$, the following reciprocity relation can be shown to be true:

$$\int_D \rho[\bar{u}\cdot(\bar{\bar{C}}\cdot\bar{v}) - \bar{v}\cdot(\bar{\bar{C}}\cdot\bar{u})]d\tau = \int_B [\bar{u}\cdot\bar{T}(\bar{v}) - \bar{v}\cdot\bar{T}(\bar{u})]d\sigma. \tag{2.3}$$

III. Potential of Volume Distribution. In this section a vector function is constructed which is analogous to the potential of a volume distribution. The vector is generated by integration of the product of a piecewise continuous vector density distribution $\bar{\lambda}$ and a singular dyadic $\bar{\bar{U}}$:

$$\bar{u}(P) = \int_D \bar{\lambda}(Q)\cdot\bar{\bar{U}}_s(P, Q)d\tau_Q, \tag{3.1}$$

where P: (x, y, z), Q: (ξ, η, ζ), $r^2 = (\xi-x)^2+(\eta-y)^2+(\zeta-z)^2$,

$$\bar{\bar{U}}_s(P, Q) = \frac{1}{4\pi\rho k^2}\nabla\nabla\left(\frac{e^{\alpha r(P,Q)} - e^{\beta r(P,Q)}}{r(P, Q)}\right) + \frac{e^{\alpha r(P,Q)}}{4\pi\rho a^2 r(P, Q)}\bar{\bar{I}},$$

$$\alpha = \frac{ik}{a}; \quad \beta = \frac{ik}{b}; \quad \text{and} \quad i^2 = -1.$$

It is observed that the integrand in (3.1) is singular and therefore the integral must be checked for convergence. In addition if information about the various derivatives of $\bar{u}$ is required, further investigation is necessary. Before proceeding with this task, we shall look carefully into the behavior of $\bar{\bar{U}}_s$ in the vicinity of $r=0$. After the various exponentials in their appropriate series are expanded, $\bar{\bar{U}}_s$ takes the form:

$$\bar{\bar{U}}_s = \frac{b^2 - a^2}{8\pi\rho a^2 b^2}\left(\frac{1}{r}\bar{e}_r\bar{e}_r\right) + \frac{1}{4\pi\rho a^2}\left(1 - \frac{b^2 - a^2}{2b^2}\right)\frac{1}{r}\bar{\bar{I}} + 0(\alpha, \beta). \tag{3.2}$$

In this expression, $\bar{e}_r$ is a unit vector directed from P to Q. We remark that the

expression for $\overline{\overline{U}}_s$ given in (3.2) is, with the exception of the final order term, the Kelvin solution for displacement due to a point load in an infinite medium. Since the order term disappears when k vanishes, all results obtained in this paper are directly applicable even if the undifferentiated term of (2.1) is nonexistent.

Inasmuch as the second term on the right of (3.2) is merely the singularity employed in ordinary potential theory it need not be treated further here. Also, since we need be concerned only with the various quantities in the immediate vicinity of $r=0$, the final term on the right side of (3.2) will not be necessary. Let $\bar{u}$ be a sum of two functions $\bar{u}_1$ and $\bar{u}_2$ where:

$$
\begin{aligned}
\bar{u}_1(P) &= \frac{b^2 - a^2}{8\pi\rho a^2 b^2} \int_D \frac{\bar{\lambda}(Q)}{r(P,Q)} \cdot \bar{e}_r \bar{e}_r d\tau_Q, \\
\bar{u}_2(P) &= \frac{1}{4\pi\rho a^2}\left(1 - \frac{b^2 - a^2}{2b^2}\right)\overline{\overline{I}} \cdot \int_D \frac{\bar{\lambda}(Q)}{r(P,Q)}\, d\tau_Q.
\end{aligned} \tag{3.3}
$$

Then $\bar{u}_2$ and its first derivatives are continuous throughout all of space. Proofs of this are numerous, the treatment of the entire subject given by O. D. Kellogg [3] being quite easy to follow.

Each term of the integral expression for $\bar{u}_1(P)$ is seen to be of the order r^{-1}; hence the integral is convergent and the function exists at all points. Furthermore, first derivatives of the function with respect to the coordinates at P will give rise to terms of order r^{-2} in the integrand which will again yield a convergent integral; in turn this means that the first derivatives exist at all points. Continuity of the function and its first order derivatives is also readily established.

IV. Potential of Surface Distribution.

1. *Definition.* Just as in the previous section, we may extend the ideas of potential theory to vector surface distributions. We define a vector distribution $\bar{\mu}(Q)$ which satisfies a uniform Hölder condition on a regular closed surface B, and construct a vector function $\bar{u}$:

$$
\bar{u}(P) = \int_B \bar{\mu}(Q) \cdot \overline{\overline{U}}_s(P, Q) d\sigma_Q. \tag{4.1}
$$

Call D_i the volume enclosed by B and D_e all space external to B. For all points P in D_i or D_e, $\bar{u}(P)$ satisfies (2.1). Clearly, the function defined by (4.1) exists and is continuous for all points in space, except possibly points on the surface B. However, since the singularity in the integrand is of order r^{-1}, it is at once obvious that $\bar{u}(P)$ exists and is continuous for points in B as well.

2. *Tangential Derivatives.* The behavior of the various partial derivatives of $\bar{u}(P)$, defined by (4.1), is best studied by establishing a set of cartesian axes at a point p of B such that the z-axis is normal to the surface and the xy plane is tangent to the surface.

As with the function itself, the existence and continuity of its partial deriva-

tives at interior points of D_i or D_e presents no problem. We are concerned, however, with the behavior of these quantities at points P which approach p along the normal to the surface at p.

As previously, we write the integral, without the terms of $\bar{\bar{U}}_s$ which are constant or of positive powers of r

$$(4.2)\quad \bar{u}(P) = \int_B \frac{\bar{\mu}(Q)}{r(P,Q)} \cdot \left[\frac{b^2 - a^2}{8\pi\rho a^2 b^2} \bar{e}_r \bar{e}_r + \frac{1}{4\pi\rho a^2} \left(1 - \frac{b^2 - a^2}{2b^2} \right) \bar{\bar{I}} \right] d\sigma_Q,$$

and again focus attention on the term involving $\bar{e}_r\bar{e}_r$. With the coordinate system oriented as mentioned, select P on the z axis. The object is to examine the limit of the various partial derivatives as z approaches zero. For example, consider the derivative with respect to x. The members of the dyadic $\bar{e}_r\bar{e}_r$ involving $\bar{\imath}\bar{k}$ and $\bar{k}\bar{\imath}$ are of the form

$$(4.3)\quad \bar{I}_1 = (\bar{\imath}\bar{k} + \bar{k}\bar{\imath}) \cdot \left[3 \int_B \bar{\mu}(Q) \frac{\xi^2(\zeta - z)}{r^5(P,Q)} d\sigma_Q - \int_B \bar{\mu}(Q) \frac{\zeta - z}{r^3(P,Q)} d\sigma_Q \right].$$

The limit of the second integral is given in [3]. It is

$$(4.4)\quad \lim_{z \to 0} - \int_B \bar{\mu}(Q) \frac{\zeta - z}{r^3(P,Q)} d\sigma_Q = 2\pi\bar{\mu}(p) - \int_B \bar{\mu}(Q) \frac{\zeta - z}{r^3(P,Q)} d\sigma_Q.$$

To calculate the limiting value of the other integral, the technique utilized by Kellogg may be repeated with only minor modifications.

After carrying out the necessary steps one obtains

$$(4.5)\quad \lim_{z \to 0} 3 \int_B \bar{\mu}(Q) \frac{\xi^2(\zeta - z)}{r^5(P,Q)} d\sigma_Q = -2\pi\bar{\mu}(p) + 3 \int_B \bar{\mu}(Q) \frac{\xi^2 \zeta}{r^5(P,Q)} d\sigma_Q;$$

we may now write the desired result

$$(4.6)\quad \lim_{z \to 0} \bar{I}_1 = (\bar{\imath}\bar{k} + \bar{k}\bar{\imath}) \cdot \int_B \bar{\mu}(Q) \left[\frac{\partial}{\partial x} \left(\frac{\xi(\zeta - z)}{r^3} \right) \right]_{z=0} d\sigma_Q.$$

We note that the convergence of the integral in (4.6) is readily established if one recalls that

$$|\zeta| \leqq A(\xi^2 + \eta^2), \qquad |\xi| \leqq r.$$

Utilizing the same type of analysis, it may be shown that the limits of the various other terms in the integral are of the same form as that just obtained. The combination of all these results yields

$$(4.7)\quad \left. \frac{\partial \bar{u}}{\partial x} \right|_p = \int_B \bar{\mu}(Q) \cdot \left[\frac{\partial \bar{\bar{U}}_s}{\partial x} \right]_{z=0} d\sigma.$$

It follows at once that

$$\left.\frac{\partial \bar{u}}{\partial y}\right|_p = \int_B \bar{\mu}(Q)\cdot\left[\frac{\partial \bar{\bar{U}}_s}{\partial y}\right]_{z=0} d\sigma. \tag{4.8}$$

These two expressions represent derivatives of the function $\bar{u}$ in tangential directions. The derivative in any tangential direction is a linear combination of these two. In summary, the tangential derivatives, when defined for points on B as their limiting values as the surface is approached along normals, exist and are continuous throughout space.

3. *Normal Derivatives.* The study of normal derivatives is no different in character than the work just completed. Using the set of axes employed previously, the normal derivatives are simply the derivatives with respect to z.

As the details are quite similar to the previous work, only the results will be given here. The plus and minus signs in the denominator of the derivative symbol indicate that the surface is approached through positive or negative values of z respectively. A slight refinement is given by replacing z by n_p which indicates, naturally, the normal to the surface at point p.

$$\frac{\partial \bar{u}}{\partial n_p^{\pm}} = \frac{b^2-a^2}{8\pi a^2 b^2 \rho}\bar{\mu}(p)\cdot(\mp 2\pi\bar{\bar{I}} \pm 4\pi\bar{k}\bar{k}) + \frac{1}{4\pi a^2\rho}\left(1-\frac{b^2-a^2}{2b^2}\right)\bar{\mu}(p)\cdot(\mp 2\pi\bar{\bar{I}})$$
$$+ \int \bar{\mu}(Q)\cdot\left.\frac{\partial \bar{\bar{U}}_s}{\partial n_p}\right|_{z=0} d\sigma.$$

The results just presented are, as were the others, uniform as to location of p by virtue of the uniform Hölder condition imposed on $\bar{\mu}(Q)$. For this reason the vector $\bar{u}$ and its derivatives are continuously differentiable in either D_i or D_e (cf. [3], Theorem VII, p. 165).

4. *Stress Vector of $\bar{u}$.* It is of interest to look at the limiting value of the stress vector as points on B are approached along normals. Inasmuch as the stress vector is a combination of first derivatives, the desired limit can be obtained by a judicious use of the results already obtained. For convenience, the axes used for computation will have their origin at point p of B and are oriented as described before. In these considerations, the normal will be taken as positive if directed outward from the region D, and the limit will be approached through negative values of z.

The first term of the stress vector, (2.2) is the normal derivative of $\bar{u}$, and therefore its behavior can be examined by using the results in (4.9).

The remaining two terms of the stress vector expression contain the dilatation and the rotation vector of $\bar{u}$. Both of these quantities behave as ordinary potentials for small values of r and therefore their limits are known. When the individual results are summed, we obtain

$$\bar{T}^{-}(\bar{u}) = 1/2\bar{\mu}(p) + \int_B \bar{\mu}(Q)\cdot\bar{\bar{T}}[\bar{\bar{U}}_s]_p d\sigma, \tag{4.10}$$

in which

$$(4.11)\quad \bar{\bar{T}}[\bar{\bar{U}}_s]_p = \rho\left[2a^2\frac{d\bar{\bar{U}}_s}{dn_p} + (b^2 - 2a^2)\bar{n}_p(\nabla\cdot\bar{\bar{U}}_s)_p + a^2\bar{n}_p\times(\nabla\times\bar{\bar{U}}_s)_p\right]$$

and the minus sign with the left member indicates that the approach was made from the negative or inward side of B. The sign on the leading term on the right would, of course, be reversed had the approach been from the opposite side. The result expressed in (4.10) represents the natural extension of a similar result applying to normal derivatives in the ordinary potential theory.

V. Potential of "Double Layer." Here the analog of a double layer in ordinary potential theory is considered. The kernel for such a distribution is the normal derivative of $1/r$. The corresponding kernel in our case is of the form of the dyadic kernel in (4.11) except that the derivatives are taken with respect to the roving point Q and evaluated there. As in the ordinary potential theory, we shall assume that the density distribution, $\bar{\nu}(Q)$ and its first and second derivatives are continuous. The function, which satisfies (2.1) for points not on B, is written

$$(5.1)\quad \bar{u}(P) = \int \bar{\nu}(Q)\cdot\bar{\bar{T}}_Q[\bar{\bar{U}}_s(P, Q)]d\sigma_Q.$$

As may be demonstrated, this vector is discontinuous across the surface B. To show this one recognizes that all derivatives of functions of the radius r, with respect to coordinates at Q are just the negative of the corresponding derivatives with respect to the coordinate of the fixed point P. In addition, if the coordinate system is set, as before, with the origin at p and the xy plane tangent to B, the various components of the integrand are similar to the terms arising out of the calculation of the stress vector appropriate to the vector obtained in the last section. They differ in that they have a different sign, and the density is multiplied by a direction cosine. Application of reasoning similar to that leading to the result given in (4.10) leads one to:

$$(5.2)\quad \bar{u}^- = -1/2\bar{\nu}(p) + \int \bar{\nu}(Q)\cdot\bar{\bar{T}}_Q[\bar{\bar{U}}_s(p, Q)]d\sigma_Q.$$

It is understood that the first term on the right changes in sign if the surface is approached from the opposite direction. Again, since the condition is satisfied uniformly on B, the function $\bar{u}$ is continuous in any closed region where B is only approached from one side.

We turn now to the question of continuity of first derivatives and change our mode of attack somewhat. As always, points not on B cause no great concern, and so once more our attention is directed to points p on the bounding surface.

Utilizing the reciprocity relation one may express $\bar{\nu}$ in the following way

$$\bar{v}(P) = -\int_{D^*} (\bar{\bar{C}}\cdot\bar{v})\cdot\bar{\bar{U}}_s d\tau + \int_{B^*} \bar{T}(\bar{v})\cdot\bar{\bar{U}}_s d\sigma - \int_{B^*} \bar{v}(Q)\cdot\bar{\bar{T}}[\bar{\bar{U}}_s]d\sigma,$$

where D^* and B^* are a regular region and its bounding surface. If then, D^* and B^* are constructed in the same way as explained in ([3], p. 170), the continuity of first derivatives is readily shown in a neighborhood of any point of B. Therefore the field $\bar{u}$ as defined by (5.1) is, along with its first derivatives, continuous in a closed region D bounded by B provided B is approached from one side only.

Acknowledgment: The author wishes to express his sincere appreciation to Professor M. Stippes whose suggestion of the feasibility of this work gave impetus to its pursuit.

MATHEMATICAL NOTES

TYCHONOFF'S THEOREM FOR THE SPACE OF MULTIFUNCTIONS

Y.-F. LIN, University of South Florida

1. Introduction. The classical theorem of Tychonoff states that *the cartesian product of a collection of compact topological spaces is compact relative to the product topology* [3]. "This theorem is," according to J. L. Kelley [2], "unquestionably the most useful theorem on compactness and it is probably the most important single theorem of general topology." We propose to carry this theorem to a theorem for the space of multivalued functions.

2. Space of multifunctions. Let X and Y be two topological spaces, then $F \subset X \times Y$ is said to be a *multifunction* on X to Y if F is a correspondence between elements in X and nonvoid subsets in Y. That is, to be precise, for each x in X

$$\pi_2((\{x\} \times Y) \cap F) \neq \square,$$

where π_2 is the second projection of $X \times Y$ to Y, and $\square$ denotes the empty set. We shall write $F\colon X \Rightarrow Y$ for a multifunction on X to Y and $F(x)$ for the set $\pi_2((\{x\} \times Y) \cap F)$. If $\{X_\lambda | \lambda \in \Lambda\}$ is a family of topological spaces, discrete or otherwise, then the *cartesian M-product* $P_M\{X_\lambda | \lambda \in \Lambda\}$ of the family of spaces $\{X_\lambda | \lambda \in \Lambda\}$ is the set of all multifunctions $F\colon \Lambda \Rightarrow \cup\{X_\lambda | \lambda \in \Lambda\}$ such that $F(\lambda) \subset X_\lambda$. Since each (single valued) function is also a multifunction, the cartesian product $P\{X_\lambda | \lambda \in \Lambda\}$ is a subset of the cartesian M-product $P_M\{X_\lambda | \lambda \in \Lambda\}$. We shall topologize $P_M\{X_\lambda | \lambda \in \Lambda\}$ in a manner analogous to the product topol-

ogy for $P\{X_\lambda|\lambda\in\Lambda\}$, and in such a way that the product topology will be its subtopology (relativized topology). Recall that the product topology for $P\{X_\lambda|\lambda\in\Lambda\}$ is obtained by taking as a subbasis the collection of all sets $\{f\in P\{X_\lambda|\lambda\in\Lambda\}|f(\lambda)\in U_\lambda\}$ for all λ in Λ and for all open sets U_λ in X_λ. The statement "$f(\lambda)\in U_\lambda$" has two meanings if the function f is replaced by a multifunction F; precisely, the statements "$F(\lambda)\subset U_\lambda$" and "$F(\lambda)\cap U_\lambda\neq\square$" both mean "$f(\lambda)\in U_\lambda$" if F is a single valued function f. Therefore we make the following definition.

DEFINITION. *Let $\{X_\lambda|\lambda\in\Lambda\}$ be a collection of topological spaces. By the M-product topology for $P_M\{X_\lambda|\lambda\in\Lambda\}$ is meant the topology defined by taking the totality of sets*

$$\{F\in P_M\{X_\lambda\,|\,\lambda\in\Lambda\}\,|\,F(\lambda)\subset U_\lambda\},\tag{1}$$

$$\{F\in P_M\{X_\lambda\,|\,\lambda\in\Lambda\}\,|\,F(\mu)\cap V_\mu\neq\square\},\tag{2}$$

as subbasic open sets, where U_λ and V_μ are any open sets in X_λ and X_μ respectively, and λ, u are any members of Λ.

Following A. D. Wallace [4], we shall write simply $[U_\lambda]$ and $]V_\mu[$ respectively for the sets (1) and (2) above.

THEOREM. *If $\{X_\lambda|\lambda\in\Lambda\}$ is a collection of compact spaces, then the cartesian M-product $P_M\{X_\lambda|\lambda\in\Lambda\}$ is compact relative to the M-product topology.*

Proof. By a lemma of Alexander [1], to show that $P_M\{X_\lambda|\lambda\in\Lambda\}$ is compact it suffices to show every covering by subbasic open sets has a finite subcovering. Let $\mathbf{S}$ be the totality of $[U_\lambda]$ and $]V_\mu[$ where U_λ and V_μ are open in X_λ and X_μ respectively. Suppose, to get a contradiction, that the space $P_M\{X_\lambda|\lambda\in\Lambda\}$ is not compact. Then there exists a subcollection $\mathbf{C}$ of $\mathbf{S}$ such that $\mathbf{C}$ covers $P_M\{X_\lambda|\lambda\in\Lambda\}$ but every finite subcollection of $\mathbf{C}$ fails to cover $P_M\{X_\lambda|\lambda\in\Lambda\}$. For each λ in Λ, let $\mathbf{U}_\lambda$ ($\mathbf{V}_\lambda$) be the collection of all open sets U_λ (V_λ) in X_λ such that the sets $[U_\lambda]$ ($]V_\lambda[$) are in $\mathbf{C}$. Then no finite subcollection of $\mathbf{V}_\lambda$ covers X_λ and hence by compactness of X_λ every $X_\lambda-\cup\{V_\lambda|\,V_\lambda\in\mathbf{V}_\lambda\}$ is not empty. Let $F\colon\Lambda\Rightarrow\cup\{X_\lambda|\lambda\in\Lambda\}$ be defined by

$$F(\lambda)=X_\lambda-\cup\{V_\lambda|V_\lambda\in\mathbf{V}_\lambda\}$$

for each $\lambda\in\Lambda$. Then $F(\lambda)$ is not in $\mathbf{V}_\lambda$ for all λ in Λ; also, $F(\lambda)$ cannot be in $\mathbf{U}_\lambda$ for all λ in Λ. Thus, F is not in any member of $\mathbf{C}$ and, the fact that $\mathbf{C}$ is a covering of $P_M\{X_\lambda|\lambda\in\Lambda\}$ is contradicted.

NOTE ON ITERATION OF CONCAVE FUNCTIONS

M. KUCZMA AND A. SMAJDOR, Katowice, Poland

Let $f(x)$ be a function which is continuous, strictly increasing and concave downward in an interval (a, b), $-\infty \leqq a < b \leqq \infty$, and moreover $a < f(x) < x$ in (a, b). The condition of concavity implies that at every point of (a, b) both the lateral derivatives of $f(x)$ exist and are decreasing functions. In the sequel $f'(x)$ will denote the right-sided derivative of $f(x)$.

Let $f^n(x)$ denote the nth iterate of $f(x)$ defined by the recurrence $f^{n+1}(x) = f[f^n(x)]$, $n = 0, 1, 2, \cdots$, where $f^0(x)$ is the identity function. It follows from the properties of $f(x)$ that for every n the function $f^n(x)$ is defined, continuous, and strictly increasing in (a, b). Moreover, $a < f^{n+1}(x) < f^n(x) < x$ in (a, b), and $\lim_{n\to\infty} f^n(x) = a$ for every $x \in (a, b)$.

The purpose of the present note is to prove the following result, of importance in the theory of functional equations and in the theory of iterations (cf. [1], [2]).

THEOREM. *Let $f(x)$ have the properties described above. If*

$$\lim_{x\to a+0} f'(x) = 1, \tag{1}$$

then

$$\lim_{n\to\infty} \frac{f^{n+1}(x) - f^n(x)}{f^{n+1}(y) - f^n(y)} = 1 \tag{2}$$

for every $x, y \in (a, b)$.

Proof. Without loss of generality we may assume that $y < x$. (For $y = x$, (2) is evident and the case $y > x$ is reduced to that considered by taking the reciprocals.) Then there exists a positive integer k such that

$$f^k(x) < y < x. \tag{3}$$

Since f is concave, if $t_1 < t_0$, $t_1, t_0 \in (a, b)$ then

$$f'(t_0) \leqq \frac{f(t_1) - f(t_0)}{t_1 - t_0} \leqq f'(t_1). \tag{4}$$

Taking $t_0 = f^n(x)$, $t_1 = f^{n+1}(x)$ in (4), we obtain

$$f'[f^n(x)] \leqq \frac{f^{n+2}(x) - f^{n+1}(x)}{f^{n+1}(x) - f^n(x)} \leqq f'[f^{n+1}(x)],$$

whence by (1)

$$\lim_{n\to\infty} \frac{f^{n+2}(x) - f^{n+1}(x)}{f^{n+1}(x) - f^n(x)} = 1$$

and

$$\lim_{n\to\infty}\frac{f^{n+k+1}(x)-f^{n+k}(x)}{f^{n+1}(x)-f^{n}(x)}=\lim_{n\to\infty}\prod_{i=0}^{k-1}\frac{f^{n+i+2}(x)-f^{n+i+1}(x)}{f^{n+i+1}(x)-f^{n+i}(x)}=1. \tag{5}$$

Since $f'(x)$ is decreasing, it follows from (1) that $f'(x)\leqq 1$ in (a, b). Consequently the function $f(x)-x$ is decreasing in (a, b), i.e.

$$f(u)-u\leqq f(v)-v, \quad \text{whenever } v<u, \quad u, v\in(a, b). \tag{6}$$

Both the expressions in (6) are negative; hence

$$\frac{f(u)-u}{f(v)-v}\geqq 1, \quad \text{whenever } v<u, \quad u, v\in(a, b). \tag{7}$$

Setting $u=f^n(x)$ and $v=f^n(y)$ in (7) we get

$$\frac{f^{n+1}(x)-f^{n}(x)}{f^{n+1}(y)-f^{n}(y)}\geqq 1. \tag{8}$$

On the other hand, by (3), $f^{k+n}(x)<f^n(y)$ whence, by (6), $f^{n+1}(y)-f^n(y)\leqq f^{k+n+1}(x)-f^{k+n}(x)$ and

$$\frac{f^{n+1}(x)-f^{n}(x)}{f^{k+n+1}(x)-f^{k+n}(x)}\geqq\frac{f^{n+1}(x)-f^{n}(x)}{f^{n+1}(y)-f^{n}(x)}. \tag{9}$$

We now obtain (2) from (8), (9) and (5).

DIAGONAL EQUIVALENCE TO MATRICES WITH PRESCRIBED ROW AND COLUMN SUMS

RICHARD SINKHORN, University of Houston

The author shows in [1] that corresponding to each positive square matrix A there is a unique doubly stochastic matrix of the form D_1AD_2 where D_1 and D_2 are diagonal matrices with positive main diagonals. This doubly stochastic matrix can be obtained as a limit of the iterative process of alternately normalizing the rows and columns of A. It is the intent of this paper to generalize this result in the following way.

THEOREM. *Let $r_1, \cdots, r_m$, $c_1, \cdots, c_n$ be fixed positive numbers. Then, corresponding to each positive $m\times n$ matrix A, there is a unique matrix of the form D_1AD_2 with row sums $\mu r_1, \cdots, \mu r_m$ and column sums $c_1, \cdots, c_n$ where $\mu=\sum_j c_j/\sum_i r_i$. D_1 and D_2 are respectively $m\times m$ and $n\times n$ diagonal matrices*

with positive diagonals and are themselves unique up to a scalar multiple.

The iterative process of alternately scaling the rows and columns of A to have row and column sums respectively r_i and c_j can be used to find D_1AD_2. The subsequence from the iteration in which column sums are scaled converges to D_1AD_2 while the subsequence in which the row sums are scaled converges to $(1/\mu)D_1AD_2$. In particular, if $\sum_i r_i = \sum_j c_j$ then the entire iteration converges to D_1AD_2.

The uniqueness part of the theorem is immediate. Suppose that D_1AD_2 and $D_1'AD_2'$ satisfy the requirements of the theorem where

$$D_1 = \operatorname{diag}(x_1, \cdots, x_m), \qquad D_1' = \operatorname{diag}(x_1', \cdots, x_m'),$$
$$D_2 = \operatorname{diag}(y_1, \cdots, y_n), \quad \text{and} \quad D_2' = \operatorname{diag}(y_1', \cdots, y_n').$$

Then, if $p_i = x_i'/x_i$ $(i=1, \cdots, m)$, and $q_j = y_j'/y_j$ $(j=1, \cdots, n)$,

$$\begin{aligned}\operatorname{Min} p_i &= p_{i_1} = \mu r_{i_1}\Big(\sum_j x_{i_1}a_{i_1j}q_jy_j\Big)^{-1} \\ &\geqq \mu r_{i_1}(\operatorname{Max} q_j)^{-1}\Big(\sum_j x_{i_1}a_{i_1j}y_j\Big)^{-1} = (\operatorname{Max} q_j)^{-1},\end{aligned}$$

and, similarly, $\operatorname{Max} q_j \leqq (\operatorname{Min} p_i)^{-1}$.

These inequalities are compatible only if each inequality is an equality. But equality in the former case forces $q_j = \operatorname{Max} q_j = q$, a positive constant for $j=1, \cdots, n$; in the latter case it forces $p_i = \operatorname{Min} p_i = p$, a positive constant for $i=1, \cdots, m$. Either equality then shows that $q = p^{-1}$. Thus $D_1' = pD_1$, $D_2' = p^{-1}D_2$ and $D_1AD_2 = D_1'AD_2'$.

The existence part of the theorem follows at once from the following lemma. The proof of the lemma justifies the statements regarding the iteration.

LEMMA. *Let $V \subseteq R^m \times R^n$ denote the set of pairs of vectors (x, y) with positive components such that $\sum_i x_i a_{ij} y_j = c_j$ $(j=1, \cdots, n)$, and $\|x\| = \operatorname{Max}|x_i| \leqq \delta^{1/2}a^{-1/2}$, $\|y\| = \operatorname{Max}|y_j| \leqq \delta^{1/2}a^{-1/2}$ where $\delta = \operatorname{Max}(r_i, c_j)$ and $a = \operatorname{Min} a_{ij}$, and let*

$$\phi(x, y) = \operatorname*{Max}_i r_i^{-1} \sum_j x_i a_{ij} y_j - \operatorname*{Min}_i r_i^{-1} \sum_j x_i a_{ij} y_j$$

have domain of definition V. Then $\phi(\hat{x}, \hat{y}) = 0$ for some $(\hat{x}, \hat{y}) \in V$.

Proof. First note that V is nonvoid since it contains (x^0, y^0) with components

$$x_{i0} = \delta^{1/2}a^{-1/2}, \quad y_{j0} = c_j\delta^{-1/2}a^{1/2}\Big(\sum_i a_{ij}\Big)^{-1}.$$

Construct a sequence $(x^k, y^k) \in V$ as follows beginning with (x^0, y^0): Let $\alpha_{ik} = r_i^{-1}\sum_j x_{ik}a_{ij}y_{jk}$ and $\beta_{jk} = c_j^{-1}\sum_i \alpha_{ik}^{-1}x_{ik}a_{ij}y_{jk}$ and use

$$x_{i,k+1} = \delta^{1/2}a^{-1/2}M_k^{-1}\alpha_{ik}^{-1}x_{ik}$$

$$y_{j,k+1} = \delta^{-1/2}a^{1/2}M_k\beta_{jk}^{-1}y_{jk}$$

as the components of (x^{k+1}, y^{k+1}) where $M_k = \operatorname{Max}_i \alpha_{ik}^{-1}x_{ik}$.

Since for any j

$$\beta_{jk}^{-1}y_{jk} = (\sum_i \alpha_{ik}^{-1}x_{ik}a_{ij})^{-1}c_j \leqq (\alpha_{ik}^{-1}x_{ik}a_{ij})^{-1}c_j \leqq (\alpha_{ik}^{-1}x_{ik})^{-1}a^{-1}\delta$$

for all i, it is true in particular that $\beta_{jk}^{-1}y_{jk} \leqq \mathrm{Min}_i(\alpha_{ik}^{-1}x_{ik})^{-1}a^{-1}\delta = M_k^{-1}a^{-1}\delta$ for all j. It readily follows that each $(x^k, y^k) \in V$.

Denoting Min α_i and Max α_i by α_{i_1} and α_{i_2} and Min β_j and Max β_j by β_{j_1} and β_{j_2} respectively, we see that

$$\begin{aligned}
\phi(x^{k+1}, y^{k+1}) &= \alpha_{i_2,k+1} - \alpha_{i_1,k+1} \\
&= r_{i_2}^{-1}\sum_j x_{i_2,k+1}a_{i_2j}y_{j,k+1} - r_{i_1}^{-1}\sum_j x_{i_1,k+1}a_{i_1j}y_{j,k+1} \\
&= r_{i_2}^{-1}\sum_j \alpha_{i_2k}^{-1}x_{i_2k}a_{i_2j}\beta_{jk}^{-1}y_{jk} - r_{i_1}^{-1}\sum_j \alpha_{i_1k}^{-1}x_{i_1,k}a_{i_1j}\beta_{jk}^{-1}y_{jk} \\
&= r_{i_2}^{-1}\alpha_{i_2k}^{-1}x_{i_2k}a_{i_2j_2}\beta_{j_2k}^{-1}y_{j_2k} + r_{i_2}^{-1}\sum_{j\neq j_2} \alpha_{i_2k}^{-1}x_{i_2k}a_{i_2j}\beta_{jk}^{-1}y_{jk} \\
&\quad - r_{i_1}^{-1}\alpha_{i_1k}^{-1}x_{i_1k}a_{i_1j_1}\beta_{j_1k}^{-1}y_{j_1k} - r_{i_1}^{-1}\sum_{j\neq j_1} \alpha_{i_1k}^{-1}x_{i_1k}a_{i_1j}\beta_{jk}^{-1}y_{jk} \\
&\leqq r_{i_2}^{-1}\alpha_{i_2k}^{-1}x_{i_2k}a_{i_2j_2}\beta_{j_2k}^{-1}y_{j_2k} + r_{i_2}^{-1}\beta_{j_1k}^{-1}\sum_{j\neq j_2} \alpha_{i_2k}^{-1}x_{i_2k}a_{i_2j}y_{jk} \\
&\quad - r_{i_1}^{-1}\alpha_{i_1k}^{-1}x_{i_1k}a_{i_1j_1}\beta_{j_1k}^{-1}y_{j_1k} - r_{i_1}^{-1}\beta_{j_2k}^{-1}\sum_{j\neq j_1} \alpha_{i_1k}^{-1}x_{i_1k}a_{i_1j}y_{jk} \\
&= \beta_{j_2k}^{-1}(\alpha_{i_2k}^{-1}x_{i_2k}a_{i_2j_2}r_{i_2}^{-1}y_{j_2k}) + \beta_{j_1k}^{-1}(1 - \alpha_{i_2k}^{-1}x_{i_2k}a_{i_2j_2}r_{i_2}^{-1}y_{j_2k}) \\
&\quad - \beta_{j_1k}^{-1}(\alpha_{i_1k}^{-1}x_{i_1k}a_{i_1j_1}r_{i_1}^{-1}y_{j_1k}) - \beta_{j_2k}^{-1}(1 - \alpha_{i_1k}^{-1}x_{i_1k}a_{i_1j_1}r_{i_1}^{-1}y_{j_1k}) \\
&= (\beta_{j_1k}^{-1} - \beta_{j_2k}^{-1})(1 - \alpha_{i_2k}^{-1}x_{i_2k}a_{i_2j_2}r_{i_2}^{-1}y_{j_2k} - \alpha_{i_1k}^{-1}x_{i_1k}a_{i_1j_1}r_{i_1}^{-1}y_{j_1k}) \\
&\leqq (\beta_{j_1k}^{-1} - \beta_{j_2k}^{-1})(1 - 2d_k),
\end{aligned}$$

where $d_k = \mathrm{Min}_{i,j}\, \alpha_{ik}^{-1}x_{ik}a_{ij}r_i^{-1}y_{jk}$.

But

$$\alpha_{ik}^{-1}x_{ik} = (\sum_j a_{ij}y_{jk})^{-1}r_i \geqq (\sum_j a_{ij})^{-1}r_i a^{1/2}\delta^{-1/2} \geqq \rho R^{-1}a^{1/2}\delta^{-1/2}$$

and

$$y_{jk} = (\sum_i a_{ij}x_{ik})^{-1}c_j \geqq (\sum_i a_{ij})^{-1}c_j a^{1/2}\delta^{-1/2} \geqq \rho R^{-1}a^{1/2}\delta^{-1/2},$$

where $\rho = \mathrm{Min}(r_i, c_j)$ and $R = \sum_{i,j} a_{ij}$. Thus, for all k

$$d_k \geqq \rho R^{-1}a^{1/2}\delta^{-1/2}a\delta^{-1}\rho R^{-1}a^{1/2}\delta^{-1/2} = \rho^2 R^{-2}a^2\delta^{-2}.$$

Furthermore, it is clear that $\alpha_{i_2k}^{-1} \leqq \beta_{jk} \leqq \alpha_{i_1k}^{-1}$ for all j and k. Hence

$$\begin{aligned}
\phi(x^{k+1}, y^{k+1}) &\leqq (\alpha_{i_2k} - \alpha_{i_1k})(1 - 2\rho^2 R^{-2}a^2\delta^{-2}) \\
&= (1 - 2\rho^2 R^{-2}a^2\delta^{-2})\phi(x^k, y^k),
\end{aligned}$$

and it follows that $\phi(x^k, y^k) \to 0$.

Since $\|x^k\| \leqq \delta^{1/2}a^{-1/2}$ and $\|y^k\| \leqq \delta^{1/2}a^{-1/2}$ for all k, the sequence $\{(x^k, y^k)\}$ has a limit point $(\hat{x}, \hat{y}) \in R^m \times R^n$. The continuity of ϕ shows in particular that

$$\phi(\hat{x}, \hat{y}) = \lim_{k \to \infty} \phi(x^k, y^k) = 0.$$

It is seen that $\beta_{j_2k}^{-1} \leqq \alpha_{i,k+1} \leqq \beta_{i_1k}^{-1}$ for all i and k. Thus $\alpha_{i_1k} \leqq \alpha_{i_1,k+1} \leqq \alpha_{i_2,k+1} \leqq \alpha_{i_2k}$ and, since $\alpha_{ik}^{-1}x_{ik} \geqq \rho R^{-1}a^{1/2}\delta^{-1/2}$, $x_{ik} \geqq \alpha_{ik}\rho R^{-1}a^{1/2}\delta^{-1/2} \geqq \alpha_{i_10}\rho R^{-1}a^{1/2}\delta^{-1/2}$ $(i = 1, \cdots, m;\ k = 0, 1, \cdots)$. This along with $y_{jk} \geqq \rho R^{-1}a^{1/2}\delta^{-1/2}$ $(j = 1, \cdots, n;\ k = 0, 1, \cdots)$, shows that $\hat{x}$ and $\hat{y}$ have positive coordinates.

Then, since $\|x^k\| \leqq \delta^{1/2}a^{-1/2}$ and $\|y^k\| \leqq \delta^{1/2}a^{-1/2}$ for all k, and $\sum_i x_{ik}a_{ij}y_{jk} = c_j$ for all j and k, $\|\hat{x}\| \leqq \delta^{1/2}a^{-1/2}$, $\|\hat{y}\| \leqq \delta^{1/2}a^{-1/2}$, and $\sum_i \hat{x}_i a_{ij}\hat{y}_j = c_j$ for all j. Thus $(\hat{x}, \hat{y}) \in V$ and the lemma is proved.

The proof of the theorem may now be completed. Using the $(\hat{x}, \hat{y})$ of the lemma, set $D_1 = \operatorname{diag}(\hat{x}_1, \cdots, \hat{x}_m)$ and $D_2 = \operatorname{diag}(\hat{y}_1, \cdots, \hat{y}_n)$. Then $\sum_i \hat{x}_i a_{ij}\hat{y}_j = c_j$ $(j = 1, \cdots, n)$, and, since $\phi(\hat{x}, \hat{y}) = 0$, $\sum_j \hat{x}_i a_{ij}\hat{y}_j = Kr_i$ $(i = 1, \cdots, m)$, where K does not depend upon i. But

$$K \sum_i r_i = \sum_i \sum_j \hat{x}_i a_{ij}\hat{y}_j = \sum_j c_j = \mu \sum_i r_i;$$

hence $K = \mu$.

A NOTE ON EXTREME POINTS

A. K. Chaudhuri and E. Tarafdar, Regional Engineering College, Durgapur 9, India

Let $F: X \to Y$ be a mapping of a topological space X into another topological space Y. A point $x \in X$ will be said to be an extreme point of X with respect to the mapping $F: X \to Y$, if there exists an open neighborhood $N(x)$ of x such that $F(x) \in \text{Bdry } F(N(x))$, where Bdry $A = A - A^0$, A^0 standing for the interior of the set A. The set of all extreme points of X with respect to the mapping $F: X \to Y$ will be denoted by $E_F(X, Y)$ and the mapping F will be said to be extreme at every point $x \in E_F(X, Y)$ and the value of the mapping $F(x)$, $x \in E_F(X, Y)$ will be called an extreme value of the mapping $F: X \to Y$.

Lemma 1. *If x is an extreme point of X with respect to the mapping $F: X \to Y$, and $N(x)$ is an open neighborhood of x such that $F(x) \in$ Bdry $F(N(x))$, then if $N'(x)$ is any other open subneighborhood of x such that $N'(x) \subset N(x)$, then $F(x)$ will also belong to* Bdry $F(N'(x))$.

Proof. We have by hypothesis $F(x) \in \text{Bdry } F(N(x))$. Let $N'(x)$ be an open subneighborhood of x such that $N'(x) \subset N(x)$. If possible, let $F(x) \in F(N'(x))^0$.

Since $N'(x) \subset N(x)$, therefore $F(N'(x)) \subset F(N(x))$. Hence if $F(x) \in F(N'(x)^0$, then $F(x)$ must also belong to $F(N(x))^0$ which is a contradiction. Hence the lemma is proved.

THEOREM. *If $F: X \to Y$ is a continuous mapping of a locally connected space X satisfying the second axiom of countability into the real line Y, then the set of the extreme values of the mapping F must be countable at most.*

Proof. Let x be any point $\in E_F(X, Y)$. Then there exists an open neighborhood $N(x)$ of x such that $F(x) \in \text{Bdry } F(N(x))$. Since X is locally connected, there exists a connected open neighborhood $U(x)$ of x such that $U(x) \subset N(x)$. Then according to the Lemma 1, $F(x) \in \text{Bdry } F(U(x))$. Let us consider the family Ω of open connected sets such that for any arbitrarily chosen $x \in E_F(X, Y)$ it will be possible to find at least one $U \in \Omega$ such that $x \in U$ and $F(x) \in \text{Bdry } F(U)$. Since X satisfies the second axiom of countability, there is a countable open base $\{O_\alpha\}$ of X. Hence it is possible to find an $O \in \{O_\alpha\}$ such that $x \in O \subset U$. Hence as x runs over $E_F(X, Y)$ the corresponding set O runs over a subfamily of $\{O_\alpha\}$. Since the sets O are countable, the corresponding sets $U \in \Omega$ are also countable. Let $\{U_\alpha\}$ be the countable family of sets U so obtained.

For any $x \in E_F(X, Y)$ it will be possible, obviously, to select one $U_\alpha \in \{U_\alpha\}$ such that $x \in U_\alpha$ and $F(x) \in \text{Bdry } F(U_\alpha(x))$, by construction of the family $\{U_\alpha\}$. Since F is continuous and U_α is connected for each α, $F(U_\alpha)$ is also connected for each α and it will have at most two boundary points. Also $\{F(U_\alpha)\}$ is countable family of connected sets. Hence $\bigcup_\alpha \text{Bdry } F(U_\alpha)$ is countable at most. Again let $y \in F(E_F(X, Y))$. Therefore $F^{-1}(y) \cap E_F(X, Y) \neq \phi$. Let x_1 be a point $\in F^{-1}(y) \cap E_F(X, Y)$. Then there exists a $U \in \{U_\alpha\}$ such that $x_1 \in U$ and $F(x_1) \in \text{Bdry } F(U)$. Hence $y = F(x_1) \in \text{Bdry } F(U)$. Therefore $F(E_F(X, Y)) \subset \bigcup_\alpha \text{Bdry } F(U_\alpha)$ which is at most countable, proving the theorem.

IMBEDDING AN ARBITRARY RING IN A NONTRIVIAL NEAR-RING

JAMES R. CLAY, University of Arizona

Let R be a ring and let M be a module over R as defined in [1] or [2]. Let $N = R \times M$. For (r_1, m_1), $(r_2, m_2) \in N$, define $+$ by

$$(r_1, m_1) + (r_2, m_2) = (r_1 + r_2, m_1 + m_2) \tag{1}$$

and define $*$ by

$$(r_1, m_1) * (r_2, m_2) = (r_1 r_2, r_1 m_2 + m_1). \tag{2}$$

It is immediate that $(N, +)$ is a group and that $(N, *)$ is a semigroup.

Let $(r_3, m_3) \in N$ also. Then

$$\begin{aligned}[(r_1, m_1) + (r_2, m_2)] * (r_3, m_3) &= (r_1 + r_2, m_1 + m_2) * (r_3, m_3) \\ &= ((r_1 + r_2)r_3, (r_1 + r_2)m_3 + m_1 + m_2)\end{aligned} \tag{3}$$

and

$$
\begin{aligned}
&(r_1, m_1) * (r_3, m_3) + (r_2, m_2) * (r_3, m_3) \\
&\qquad = (r_1r_3, r_1m_3 + m_1) + (r_2r_3, r_2m_3 + m_2) \\
&\qquad = (r_1r_3 + r_2r_3, r_1m_3 + m_1 + r_2m_3 + m_2) \\
&\qquad = ((r_1 + r_2)r_3, (r_1 + r_2)m_3 + m_1 + m_2).
\end{aligned} \tag{4}
$$

From (3) and (4) we see that $*$ is right distributive over $+$.

It is easy to see that $*$ is not left distributive over $+$. Let (r, g) be an arbitrary element of N and suppose g' is not the zero element of M. Then

$$(0, g') * [(r, g) + (r, g)] = (0, g') * (r + r, g + g) = (0, g') \tag{5}$$

and

$$(0, g') * (r, g) + (0, g') * (r, g) = (0, g') + (0, g') = (0, g' + g'). \tag{6}$$

From (5) and (6) we see that $*$ cannot be left distributive over $+$.

It follows that $(N, +, *)$ is a near-ring but not a ring. It remains to show that R can be imbedded in N. Define $\phi: R \to R$ by $\phi(r) = (r, 0)$. It is easy to see that $\phi(r_1+r_2) = \phi(r_1)+\phi(r_2)$ and that $\phi(r_1r_2) = \phi(r_1) * \phi(r_2)$ for $r_1, r_2 \in R$. Certainly ϕ is one-to-one onto $N' = \{(r_1,0): r \in R\}$, and $(N', +, *)$ is a ring. Hence R and N' are isomorphic and ϕ is an imbedding map.

Similarly, the map $\pi: M \to N$ defined by $\pi(m) = (0, m)$ imbeds M into the group $(N, +)$.

If R has an identity element 1 and if $1m = m$ for every $m \in M$, then $(1, 0)$ is an identity for the near-ring N.

Let R^+ denote the additive group of R. Then R^+ is a module over R and R can be imbedded into the near-ring $R \times R^+$ as above.

ON THE THEOREM ON THE PRIMITIVE ELEMENT

J. Sonn and H. Zassenhaus, Ohio State University

In 1947 Artin remarked [1] that the known proofs of the theorem on the existence of a primitive element, in a finite separable extension of an arbitrary ground field, were uniformly marred by being divided into two cases of finite and infinite fields. The purpose of this note is to present a unified proof of the theorem.

Theorem. (Theorem on the Primitive Element) *Let E be a finite separable extension of a field F of degree $n > 1$. Then $E = F(\theta)$ for some θ in E.*

Proof. Let D be a minimal splitting field of E over F. Then there are exactly n distinct isomorphisms of E into D, say $s_1, s_2, \cdots, s_n$ where s_1 is the identity isomorphism. The $n-1$ subfields defined by the equations $s_i(a)=a$, $i=2, \cdots, n$, are, by the degree theorem, of degree at most $n/2$ over F. It remains to prove that there is an element θ in E lying outside of all these $n-1$ subfields; for then θ is of degree n over F and hence generates E.

Let $u_1, \cdots, u_n$ be a basis of E over F, and consider the set S of the 2^n elements $\sum_{i=1}^{n} e_i u_i$, $e_i=0, 1$. If it can be shown that each of the $n-1$ subfields contains at most $2^{n/2}$ elements of S, then the inequality $(n-1)2^{n/2}<2^n$ for $n>1$ completes the proof. That this is indeed the case is an immediate consequence of the following lemma.

LEMMA 1. *Let L be a linear space of dimension n over a field F, with basis $u_1, \cdots, u_n$. Then any subspace W of dimension m contains at most 2^m elements of the set $S=\left\{ \sum_{i=1}^{n} e_i u_i \middle| e_i=0, 1 \right\}$.*

Proof. Let $w_1, \cdots, w_m$ be a basis of W, and let $s \in S \cap W$. Then $s=\sum_{i=1}^{m} c_i w_i (c_i \in F)$ and, if $w_i=\sum_{j=1}^{n} w_{ij} u_j (w_{ij} \in F)$, there results a system of linear equations $\sum_{i=1}^{m} c_i w_{ij}=s_j$ $(j=1, \cdots, n)$, where $s=\sum_{j=1}^{n} s_j u_j$. Since this system has rank m, the unique solution $c_1, \cdots, c_m$ is completely determined by m of the coordinates s_j of s. As s varies in $S \cap W$, each of these m coordinates can be assigned at most two values (0 or 1) giving at most 2^m possible solutions $c_1, \cdots, c_m$.

When is the maximum value 2^m attained?

To answer this question the use of the language of affine geometry is appropriate.

DEFINITION. *A d-dimensional parallelotope with base point P_0 and edge vectors $u_1, u_2, \cdots, u_d$ is defined as the subset π_d of the n-dimensional affine space A_n over F that is obtained by producing the set $S_d=\left\{ \sum_{i=1}^{d} e_i u_i \middle| e_i=0, 1 \right\}$ of 2^d linear combinations of d independent n-vectors $u_1, u_2, \cdots, u_d$ over F from the point P_0 of the A_n. The members of π_d are called the vertices of π_d.*

Every vertex of π_d can serve as base point. If the characteristic of F is not 2, then for a fixed base point, only the $d!$ permutation s of a given system of edge vectors leads to other systems of edge vectors. If the characteristic of F is 2 then any of the $(2^d-1)(2^d-2) \cdots (2^d-2^{d-1})$ systems of d linearly independent vectors of S_d will be systems of edge vectors, no matter which vertex will be chosen as base point. We note that in the latter case S_d is a d-dimensional linear space over the prime field.

LEMMA 2. *If a d-dimensional linear manifold W of the A_n has 2^d points in common with an n-dimensional parallelotope π_n, then the intersection $W \cap \pi_n$ is a d-dimensional parallelotope.*

For any point P_0 of $W \cap \pi_n$ as basepoint, there is a system of edge vectors $u_1, \cdots, u_n$ of π_n such that the edge vectors of $W \cap \pi_n$ are of the form

(1) $u_{\alpha_{i-1}+1} + \cdots + u_{\alpha_i}$ $(1 \leqq i \leqq d;\ 0 = \alpha_0 < \alpha_1 < \cdots < \alpha_d \leqq n)$.

The converse is obvious.

Proof. If the characteristic of F is 2 apply the remark preceding the lemma. If $d=0$ then Lemma 2 is trivial.

Let char $F \neq 2$. Let $d>0$, $n>0$. Apply induction over $d+n$. Let W be a $(d+1)$-dimensional linear manifold having at least 2^{d+1} points in common with π_{n+1} one of which be P_0. Let $u_1, u_2, \cdots, u_{n+1}$ be a system of edge vectors of π_{n+1} from P_0. Let P_1 be the vertex obtained upon producing u_{n+1} from P_0. Let L_0, L_1 be the linear manifolds that are generated by producing the linear combinations of $u_1, \cdots, u_n$ from P_0, P_1 respectively. It follows that the intersections $L_0 \cap \pi_{n+1}$, $L_1 \cap \pi_{n+1}$ are disjoint n-dimensional parallelotopes, at least one of which has 2^d points in common with W. Say there are 2^d points in common to $L_0 \cap \pi_{n+1}$ and W. If W is contained in L_0 then the statement of Lemma 2 follows by application of the inductive hypothesis to L_0, $L_0 \cap \pi_{n+1}$, W. If W is not contained in L_0, then the intersection $W \cap L_0$ is a d-dimensional linear manifold. By the inductive hypothesis, the intersection $W \cap L_0 \cap \pi_n$ is a d-dimensional parallelotope with base point P_0 and edge vectors (1) (after suitable renumbering of $u_1, \cdots, u_n$). It follows that $W \cap L_1$ is a d-dimensional linear manifold which has 2^d points in common with $L_1 \cap \pi_{n+1}$. By the inductive hypothesis, $L_1 \cap \pi_{n+1}$ is a d-dimensional parallelotope. There is a vertex P_1' of $W \cap L_1 \cap \pi_{n+1}$ such that the vector from P_0 to P_1' is of the form: $u_{\beta_1} + u_{\beta_2} + \cdots + u_{\beta_s} + u_{n+1}$ $(0 < \beta_1 < \beta_2 < \cdots < \beta_s < n+1)$ with minimal value of s. The vertices of $W \cap L_1 \cap \pi_{n+1}$ are obtained by producing certain nontrivial linear combinations of the vectors (1) from P_1'. Because of the minimality of s none of the d index sets $(1 \leqq i \leqq d)$ is contained in the index set $\{\beta_1, \beta_2, \cdots, \beta_s\}$. The coefficients of the linear combinations are 0 or 1. Since there are actually 2^d such linear combinations, all combinations of 0's and 1's do occur. Hence there is no overlap between any index set $\{\alpha_{i-1}+1, \cdots, \alpha_i\}$ and $\{\beta_1, \cdots, \beta_s\}$. Thus the lemma follows. (Renumber $u_1, \cdots, u_{n+1}$ again if necessary!)

There is an extension of the theorem of the primitive element to any extension E' of a field of prime characteristic p that is obtained by a separable extension E of finite degree n followed by one purely inseparable adjunction of degree $p^v > 1$. It is again claimed that E' can be obtained by the adjunction of just one element to F.

We prove the extension by means of Lemma 1 as follows: There are precisely n distinct isomorphisms of E' into a minimal splitting field of E' over F, say $s_1, \cdots, s_n$. The $n-1$ subfields E_i' of E which are defined by the equations: $s_i(a) = s_1(a)$ $(1 < i \leqq n)$ are of degree at most $np^v/2$ over F. Furthermore there is precisely one extension E_1' of E of degree p^{v-1} contained in E'. An element θ of E' which is not contained in any one of the fields $E_1', \cdots, E_n'$ must be a primitive element. Indeed, θ^{p^v} is an element of E which does not belong to any subfield $E_i = E \cap E_i'$ $(1 < i \leqq n)$ and hence it generates E over F. But since θ

is not contained in E_1' it follows that $E(\theta)=E'$ and thus $E'=F(\theta)$.

Let $u_1, u_2, \cdots, u_{np^v}$ be a basis of E over F; consider the set S of the 2^{np^v} elements $\sum_{i=1}^{np^v} e_i u_i$, $e_i=0,1$. From Lemma 1 it follows that S intersects E_i in at most $2^{np^v/2}$ elements and since $n2^{np^v/2}<2^{np^v}$ it follows that S contains a primitive element.

DEGENERATE LOCI AND PROPER CYLINDRICAL SURFACES

D. C. B. MARSH, Colorado School of Mines

1. In a previous paper [1; Theorem 9] the author gave a necessary and sufficient condition for the existence of a "curve-locus" for a nonhomogeneous quadratic equation in n variables. Not considered was the equally important problem of determining all such loci. This note serves to resolve that question and in so doing provides an alternate proof of a recent theorem by Underwood [2; Theorem 6].

The reader may wish to refer to these definitions:

A *linear plotting rule* (L.P.R.) for $f(1, x_1, x_2, \cdots, x_n)=0$ is a pair of equations of the form

$$y_i = c_{i0} + \sum_{j=1}^{n} c_{ij}x_j, \quad i = 1, 2,$$

where $(c_{11}, c_{12}, \cdots, c_{1n})$ and $(c_{21}, c_{22}, \cdots, c_{2n})$ are linearly independent and, for each subscript j, c_{1j} and c_{2j} are not both zero. Alternatively, an L.P.R. is given by $y=Cx$ where $x=(1, x_1, x_2, \cdots, x_n)'$, $y=(1, y_1, y_2)'$, and

$$C = \begin{bmatrix} 1 & 0 & 0 & \cdots & 0 \\ c_{10} & c_{11} & c_{12} & \cdots & c_{1n} \\ c_{20} & c_{21} & c_{22} & \cdots & c_{2n} \end{bmatrix}$$

is of rank 3 and has no zero column. (Underwood places no restriction on the rank of C, but the author finds it both advantageous and reasonable to do so.)

Under these conditions one may eliminate two of the x_j, say x_1 and x_2, from $f(1, x_1, x_2, \cdots, x_n)$ to obtain $g(1, y_1, y_2, x_3, \cdots, x_n)$ which is then regarded as a function of y_1 and y_2 alone.

The *locus* of $g(1, y_1, y_2, x_3, \cdots, x_n)=0$ is the totality of points (y_1, y_2) obtained by the L.P.R. from all sets $\{x_j\}$ which satisfy $f(1, x_1, x_2, \cdots, x_n)=0$. *A* locus is a *curve-locus* under an L.P.R. if all x_j occur vacuously in g; that is, if $g(1, y_1, y_2, x_3, \cdots, x_n)=g(1, y_1, y_2)$.

Since a nondegenerate conic section in the y_1, y_2-plane can represent the

A CONGRUENCE FOR $\tau(p^{4m})$

J. M. GANDHI, University of Alberta, Edmonton

1. Ramanujan's τ function is defined by

$$x\prod_{r=1}^{\infty}(1-x^r)^{24}=\sum_{n=1}^{\infty}\tau(n)x^n. \tag{1.1}$$

Gandhi [1] and Lehmer in an unpublished paper, made the conjecture that if p is a prime and θ be determined by $p=2^\theta n-1$, n being odd, then

$$\tau(p)\equiv 0 \pmod{2^\theta}, \qquad \tau(p)\not\equiv 0 \pmod{2^{\theta+1}}. \tag{1.2}$$

This conjecture was verified to be correct by Gandhi [1] for values of $\theta=1, 2, \cdots, 9$.

On the basis of (1.2), Gandhi [1] proved the following congruences

$$\tau(p^{4m+1})\equiv 0 \pmod{2^\theta}, \qquad \tau(p^{4m+1})\not\equiv 0 \pmod{2^{\theta+1}} \tag{1.3}$$

$$\tau(p^{4m+2})-1\equiv 0 \pmod{2^\theta}; \qquad \tau(p^{4m+2})-1\not\equiv 0 \pmod{2^{\theta+1}}. \tag{1.4}$$

$$\tau(p^{2^km-1})\equiv 0 \pmod{2^{\theta+k-1}}; \qquad \tau(p^{2^km-1})\not\equiv 0 \pmod{2^{\theta+k}}. \tag{1.5}$$

These congruences enable us to find the maximum power of 2 that will divide $\tau(p^{2m+1})$ and also the maximum power of 2 that will divide $\tau(p^{4m+2})-1$. In this note we prove that for $k>1$,

$$\begin{aligned}&\tau(p^{2^kR})-1\equiv 0 \pmod{2^{k+2\theta-2}},\\ &\tau(p^{2^kR})-1\not\equiv 0 \pmod{2^{k+2\theta-1}},\end{aligned} \tag{1.6}$$

and this gives us the maximum power of 2 that will divide $\tau(p^{4m})-1$. Since

$$\tau(mk)=\tau(m)\tau(k), \quad (m,k)=1, \tag{1.7}$$

using the above congruences we are now in a position to tell the maximum power of 2 that divides $\tau(n)$ when n is odd but not an odd square, while when n is an odd square, then also we know the maximum power of 2 which will divide $\tau(n)-1$.

2. To prove (1.6) we use the following identification given by Gandhi [1]

$$\tau(p^m)=\sum_{j=0}^{[m/2]}(-1)^j\binom{m-j}{m-2j}p^{11j}\tau^{m-2j}(p). \tag{2.1}$$

Let us consider $m=2^kR$, $k>1$. Changing the summation index in (2.1) to $r=2^{k-1}R-j$, we have

$$\tau(p^{2^kR})-1=\sum_{r=1}^{2^{k-1}R}(-1)^r\binom{2^{k-1}R+r}{2r}p^{11(2^{k-1}R-r)}\tau^{2r}(p). \tag{2.2}$$

Now consider

$$(2.3) \qquad \binom{2^{k-1}R + r}{2r} = \frac{(2^{k-1}R + r) \cdots (2^{k-1}R) - (2^{k-1}R - r + 1)}{(2r)!}.$$

Excluding the term $2^{k-1}R$, there are $(2r-1)$ factors of which r are odd factors and $(r-1)$ even factors, hence the numerator contains a factor $2^{k-1+r-1}$. By elementary methods it can be proved that the highest power of 2 which can divide $(2r)!$ is 2^{2r-1}. This proves that 2^{k-1-r} divides the left hand side of (2.3). Assuming (1.2), $\tau(p) = 2^\theta u$, u being odd. For each $r \geqq 0$ the corresponding term in (2.2) is divisible by

$$2^{k-1-r}\, 2^{\theta(2r)} = 2^{k-1+(2\theta-1)r}.$$

The term for $r=1$ in (2.2) is an odd multiple of $2^{k+2\theta-2}$, hence the congruence (1.6) follows.

(Note that Congruence (1.5) of paper [1] is misprinted and should read as (1.4) given in this paper.)

Acknowledgment. My thanks are due to Professor H. Gupta for his kind encouragement. The author is on leave from the University of Rajasthan, Jaipur, India.

A CHARACTERIZATION OF THE EXPONENTIAL DISTRIBUTION

M. S. SRIVASTAVA, Princeton University

1. Introduction. Characterization of the exponential distribution has recently been considered by many authors (Ferguson [1], and Tanis [2]) and several theorems based on properties of some suitable statistics have been given. The purpose of this note is to add one more to the existing set of theorems to characterize the exponential distribution whose probability density function is given by

$$(1) \qquad f(x) = (1/\sigma)e^{-(x-\theta)/\sigma}, \qquad x > \theta,\ \sigma > 0.$$

2. A characterization of the exponential distribution. The following theorem characterizes the exponential distribution.

THEOREM. *Let F be an absolutely continuous distribution function of the random variable X with $F(\theta) = 0$, $\theta > 0$ and with probability density function $f(x)$ (hereafter, pdf). Let $X_1 < X_2 < \cdots < X_n$ denote the order statistics of a random sample of size n from this distribution. Then, in order that the statistics $X_{m+1} - X_m$ and X_m for fixed m, $1 \leqq m < n$, be independent, it is necessary and sufficient that the random variable X has the exponential distribution.*

Proof. Necessity: Let $X_m = U$ and $X_{m+1} = V$. Then the pdf. of U is

$$(n!/(m-1)!(n-m)!)(F(u))^{m-1}(1-F(u))^{n-m}f(u),$$

and the joint pdf. of U and V is

$$(n!/(m-1)!(n-m-1)!)(F(u))^{m-1}(1-F(v))^{n-m-1}f(u)f(v).$$

Consequently, the conditional pdf. of $V \mid U=u$ is

$$(n-m)[(1-F(v))^{n-m-1}/(1-F(u))^{n-m}]f(v). \tag{2}$$

It is our desire to show that if $V-U$ and U are independent, then X has the exponential distribution. Because of the independence of $V-U$ and U, $E(V-U) = E(V-U \mid U=u)$ and is free of u. Thus

$$\begin{aligned} E(V-U) &= E(V-U \mid U=u) \\ &= (n-m)\int_u^\infty (v-u)[(1-F(v))^{n-m-1}/(1-F(u))^{n-m}]f(v)dv, \end{aligned} \tag{3}$$

and is free of u. Differentiating (3) with respect to u, we have with probability one

$$0 = -\int_u^\infty [(1-F(v))^{n-m-1}/(1-F(u))^{n-m}]f(v)dv + \frac{(n-m)f(u)}{1-F(u)}E(V-U).$$

Since $E(V-U)$ is independent of u and the first expression on the right is constant, we have

$$f(u)/(1-F(u)) = \beta, \tag{4}$$

where β is a constant different from zero. Consequently,

$$1-F(u) = e^{-\beta u+d}, \tag{5}$$

and

$$f(u) = \beta e^{-\beta u+d}, \tag{6}$$

where d is a constant of integration. But, since f is a probability density function over the range θ to ∞, it follows that $d=\beta\theta$, and $\beta>0$. Hence,

$$f(x) = \beta e^{-\beta(x-\theta)}, \qquad x>\theta, \beta>0. \tag{7}$$

Sufficiency. Now, suppose that the distribution of X is given by (7). Then the joint density of U and V is

$$= \beta^2(n!/(m-1)!(n-m-1)![1-e^{-\beta(u-\theta)}]^{m-1}e^{-(n-m)\beta(v-\theta)-\beta(u-\theta)}. \tag{8}$$

Consequently, the joint density of $Z=V-U$ and $W=U$ is

$$= \beta^2(n!/(m-1)!(n-m-1)!)[1-e^{-\beta(w-\theta)}]^{m-1}e^{-(n-m+1)\beta(w-\theta)}e^{-(n-m)\beta z}, \tag{9}$$

$$z>0, w>\theta.$$

Hence, Z and W are independent. The density of Z is given by

$$(n - m)\beta e^{-(n-m)\beta z}, \qquad z > 0,$$

and the density of W is given by

$$\beta(n!/(m-1)!(n-m)!)\left[1 - e^{-\beta(w-\theta)}\right]^{m-1} e^{-(n-m+1)\beta(w-\theta)}, \qquad w > \theta.$$

A CHARACTERISTIC PROPERTY OF THE ELLIPSOID

ROLF SCHNEIDER, University of Frankfurt, Germany

Stamm [3] proved (what had been suggested by Blaschke [1], p. 232) that an ovaloid in three-space must be a sphere if it has the following property: The surface area of the zone lying between two parallel planes which cut the surface is always proportional to the distance between the planes. Here we shall give a similar characterization of the ellipsoid by a certain volume property.

Let B be a centrally symmetric convex body with interior points in three-dimensional Euclidean space, and let z be its centre. Let $T(u)$ be the supporting plane of B with unit normal vector u such that u points into that half-space which does not contain B. Let $h>0$ be a real number not greater than the distance of z from $T(u)$, and denote by $C(u, h)$ the solid "cap" which one of the planes parallel to $T(u)$ and at distance h from it cuts from B. Let $V(u, h)$ be the volume of the convex hull of $C(u, h)$ and z. For a solid sphere of radius r we have $V(u, h) = \frac{2}{3}\cdot\pi r^2 h$, and hence for a solid ellipsoid $V(u, h)$ is, for fixed u, proportional to h, where the proportionality factor depends on u. We want to invert this assertion, but we are only able to do this under the additional assumption that the boundary ∂B of B is sufficiently smooth:

THEOREM. *Let the centrally symmetric convex body B have its boundary of class C^2 and of positive Gaussian curvature. If $V(u, h)$ is always proportional to h, where the proportionality factor may depend on u, then B is bounded by an ellipsoid.*

Proof. We shall make use of the so-called "affine support function," known from the affine differential geometry of surfaces (see Blaschke [2]):

Let x be a variable point on the surface ∂B, where local parameters u^1, u^2 have been introduced. (We denote a point and its position vector with respect to some coordinate system by the same symbol.) Put

$$x_i = \frac{\partial x}{\partial u^i} \quad \text{and} \quad b_{ik} = |\, x_1, x_2, x_{ik}\,|, \quad 1 \leqq i, k \leqq 2,$$

where $|\, x_1, x_2, x_{ik}\,|$ denotes the determinant of the vectors x_1, x_2, x_{ik}. The determinant $\det(b_{ik})$ of the matrix with elements b_{ik} is positive since the curvature

of ∂B is positive. The function

$$\phi(x) = [\det(b_{ik})]^{-1/4} \left| x_1, x_2, x - z \right| \tag{1}$$

(which we may choose positive) is called the "affine support function" of ∂B with respect to z, since it resembles in some sense the ordinary support function $p(x)$, which is defined as the distance of z from the tangent plane of ∂B at x.

In the following we write $V(x, h)$ instead of $V(u, h)$, where x is the unique point of ∂B where $u = u(x)$ is assumed as outer unit normal vector (this is possible since ∂B is regular and of positive curvature). Let $\overline{V}(x, h)$ be the volume of the cap $C(u(x), h)$. Now, by a formula of Blaschke ([2], p. 128):

$$\phi(x)^2 = \frac{9}{4\pi} \lim_{h \to 0} \frac{[V(x, h) - \overline{V}(x, h)]^2}{\overline{V}(x, h)} \tag{2}$$

(which shows that $\phi(x)$ is invariant against unimodular affine transformations of space which leave z fixed).

Let $K(x)$ be the curvature of ∂B at x. Another formula of Blaschke [1], p. 120, says that

$$K(x) = \lim_{h \to 0} \left(\frac{\pi h^2}{\overline{V}(x, h)} \right)^2 . \tag{3}$$

Since we have assumed that

$$V(x, h) = k(x)h \tag{4}$$

with some function $k(x)$, (3) leads to

$$\lim_{h \to 0} \frac{[V(x, h) - \overline{V}(x, h)]^2}{\overline{V}(x, h)} = k(x)^2 \lim_{h \to 0} \frac{h^2}{\overline{V}(x, h)} = \frac{k(x)^2}{\pi} K(x)^{1/2}. \tag{5}$$

If in (4) we choose $h = p(x)$, then by the symmetry of B we get

$$V/2 = k(x)p(x), \tag{6}$$

where V is the volume of B. Furthermore, it is not difficult to deduce from (1) a representation of ϕ in terms of p and K: Writing $g_{ik} = x_i \cdot x_k$, we have

$$p(x) = [\det(g_{ik})]^{-1/2} \left| x_1, x_2, x - z \right|,$$
$$K(x) = [\det(g_{ik})]^{-1} \det(\bar{b}_{ik}),$$

where $\bar{b}_{ik} = [\det(g_{ik})]^{-1/2} b_{ik}$. This leads to

$$\phi(x) = p(x)K(x)^{-1/4}. \tag{7}$$

Now, combining (2), (5), (6), and (7), we arrive at

$$p(x) = (3V/4\pi)^{1/2} K(x)^{1/4}. \tag{8}$$

Let dA denote the element of surface area of ∂B at x. Integrating over the whole boundary of B, we have the well-known formula

$$\int p(x)dA = 3V.$$

Applying (8), we get

$$\left(\int K(x)^{1/4}dA\right)^2 = 12\pi V. \tag{9}$$

The integral $\Omega=\int K(x)^{1/4}dA$ (which can be shown to be invariant against unimodular affine transformations) is known as the "affine surface area" of ∂B. For this functional Blaschke ([2], Section 73) has proved an "isoperimetric inequality of affine differential geometry," namely

$$\Omega^2 \leqq 12\pi V.$$

Here equality characterizes ellipsoids; hence, according to (9), our theorem is proved.

PARTIALLY ORDERED FIELDS

RALPH DEMARR, University of Washington

It is well known that the real number system is a totally ordered field which is complete, in the sense that every nonincreasing sequence of nonnegative numbers has a greatest lower bound. It is of some interest to know if there are partially ordered fields which are complete in this same sense. In this note we will show that the real number field is the only partially ordered field having this completeness property. For details on partially ordered sets and algebraic systems the reader may consult Birkhoff [1], Fuchs [2], or McShane [3].

By a partially ordered field F we mean a field (not necessarily commutative) in the usual algebraic sense which is also a partially ordered set subject to the following conditions (x, y, z denote arbitrary elements of F under the specified restrictions in each condition):

(a) if $x\leqq y$, then $x+z\leqq y+z$;
(b) if $0\leqq x$ and $0\leqq y$; then $0\leqq xy$;
(c) $0<1$, where 1 is the multiplicative identity;
(d) if $0<x$, then $0<x^{-1}$;
(e) for any x there exist $y\geqq 0$ and $z\geqq 0$ such that $x=y-z$.

This is equivalent to saying that F is directed. The reader should specifically

note that we do not assume that F is lattice ordered; see [2, pp. 138–140] for a detailed discussion on lattice ordered fields. In addition to the above conditions which define a partially ordered field we shall require a weak form of order completeness called Dedekind σ-completeness; see [3, pp. 9–11]:

(f) If $\{x_n\}$ is a sequence of elements from F such that $x_1 \geqq x_2 \geqq \cdots \geqq 0$, then $\inf\{x_n\}$ exists. If $y = \inf\{x_n\}$, then this means that $y \leqq x_n$ for all n and if $z \leqq x_n$ for all n, then $z \leqq y$. Using the fact that F is a partially ordered abelian group under addition, condition (f) can be used to show that if $\{x_n\}$ is a sequence of elements from F such that $x_1 \leqq x_2 \leqq \cdots \leqq y$, then $\sup\{x_n\}$ exists. We can in fact define $\sup\{x_n\} = y - \inf\{y - x_n\}$. A partially ordered field which satisfies condition (f) above will be called a Dedekind σ-complete field. We will now prove the main theorem.

THEOREM. *Every Dedekind σ-complete field (not necessarily commutative) is order isomorphic to the real number field.*

Proof. We will first show that every Dedekind σ-complete field F is totally ordered; i.e., if $x \in F$, then $x \leqq 0$ or $0 \leqq x$. We do this by first showing that if $u \in F$ and $u \geqq 0$, then $u \leqq 1$ or $1 \leqq u$. Thus, if $u \geqq 0$, define $x_n = 1 + u + \cdots + u^n$ for all $n = 1, 2, 3, \cdots$. It is clear that $1 \leqq x_1 \leqq x_2 \leqq \cdots$; hence, $1 \geqq x_1^{-1} \geqq x_2^{-1} \geqq \cdots \geqq 0$. Therefore, $w = \inf\{x_n^{-1}\}$ exists and, of course, $w \geqq 0$. We now consider two cases.

CASE I. $w = 0$. From the fact that $(1-u)x_n = 1 - u^{n+1} \leqq 1$ we see that $1 - u \leqq x_n^{-1}$ for all n; hence, $1 - u \leqq w = 0$, which means that $1 \leqq u$.

CASE II. $w \neq 0$. This means that $x_n \leqq w^{-1}$ for all n. Hence, $v = \sup\{x_n\}$ exists. If we put $y_n = v - x_n$, then $u^{n+1} \leqq y_n$ and $\inf\{y_n\} = 0$. Therefore, $(1-u)x_n = 1 - u^{n+1} \geqq 1 - y_n$ from which it follows that $u - 1 \leqq y_n x_n^{-1} - x_n^{-1} \leqq y_n$ for all n. Hence, $u - 1 \leqq \inf\{y_n\} = 0$, which means that $u \leqq 1$.

These two cases exhaust all possibilities. Hence, if $u \geqq 0$, then $u \leqq 1$ or $1 \leqq u$. Now if we take any $x \in F$, then there exist y, $z \in F$ such that $y \geqq 0$ and $z \geqq 0$ and $x = y - z$. If $z = 0$, then $x = y \geqq 0$. If $z \neq 0$, then $yz^{-1} \geqq 0$ and, therefore, $yz^{-1} \leqq 1$ or $1 \leqq yz^{-1}$. If $yz^{-1} \leqq 1$, then $y \leqq z$ and, hence, $x = y - z \leqq 0$. If $1 \leqq yz^{-1}$, then $z \leqq y$ and, hence, $x = y - z \geqq 0$. In any event, $x \leqq 0$ or $0 \leqq x$.

Using the fact that F is Dedekind σ-complete, we may show that it has the following property: if x, $y \in F$ and $0 \leqq nx \leqq y$ for all $n = 1, 2, 3, \cdots$, then $x = 0$; for the proof see [2, p. 90]. From this we can establish that F is Archimedean (see [2], p. 12). Hence, we can use Theorem 1 on p. 126 of [2] to assert that F is order isomorphic to a subfield of the real number field. Since F contains a subfield which is order isomorphic to the rationals and since every real number is the infimum of a nonincreasing sequence of rationals, we can use the fact that F is Dedekind σ-complete to assert that F is order isomorphic to the real number field.

We will now show by examples that the above theorem could not be proved without explicitly assuming axioms (c), (d), (e), and (f). Axioms (a) and (b) are

quite natural and, therefore, we will not question them. In the first two examples F will denote the field of rational numbers and $\leqq_o$ will denote the usual ordering of the real numbers.

Example I. Axiom (c) is a consequence of axioms (b) and (d). Therefore, we must eliminate (c) and (d) simultaneously. Let $P=\{0\}\cup\{x: 2\leqq_o x\}$. Define $x\leqq y$ to mean that $y-x\in P$. It is easily verified that axioms (a), (b), (e), and (f) hold. F is not totally ordered.

Example II. Let $P=\{0\}\cup\{x: 1\leqq_o x\}$. Define $x\leqq y$ to mean that $y-x\in P$. Axioms (a), (b), (c), (e), and (f) hold. F is not totally ordered.

Example III. Let F be the field of complex numbers and define $x\leqq y$ to mean that $y-x$ is real and $0\leqq_o y-x$. Axioms (a), (b), (c), (d), and (f) hold. F is not totally ordered.

Example IV. Let F be the collection of all real-valued rational functions defined on the real line. It is clear that F is a field. We now partially order F as follows: if $x, y\in F$, then $x\leqq y$ if and only if $x(t)\leqq_o y(t)$ for all real numbers t for which both functions are defined. If we define $x_n(t)=(1+t^2+\cdots+t^{2n})^{-1}$, then $x_1\geqq x_2\geqq\cdots\geqq 0$, but $\inf\{x_n\}$ does not exist. Thus, F is a partially ordered field, but it is not Dedekind σ-complete. It is clear that F is not totally ordered and, hence, cannot be order isomorphic to the real number field.

THE BEHAVIOR OF SOLUTIONS OF THE EQUATIONS $x''\pm xx'^2\pm x^3=0$

W. R. Utz, University of Missouri

The differential equation

$$x'' + xx'^2 + q^2x^3 = 0, \qquad x' = dx/dt,$$

is satisfied by $x=\pm\sin qt$ and by $x=\pm\cos qt$. The fact that these periodic and oscillatory functions satisfy the equation suggests that all solutions may have these properties. This is established in Theorem 1. One part of the proof of this theorem is similar to the proof of a theorem of E. McHarg [1] but neither theorem implies the other.

Theorem 1. *In the equation*

$$x'' + xx'^2 + xf(x) = 0 \tag{1}$$

let $f(x)$ be an even integrable function, $f(x)>0$ for $x=0$,

$$F(x) = \int_0^x uf(u)du \to \infty \quad as\ x\to\infty.$$

Assume that solutions of (1) *are unique. If* $x=x(t)$ *is a solution of* (1) *valid for all* t, *then* $x(t)$ *is oscillatory* (*if* $x\not\equiv 0$) *and periodic.*

Proof. Let $x(t)$ satisfy (1) for all t. There is no loss in generality in taking $x(0)\geqq 0$ since $-x(t)$ also satisfies (1). For this reason, if $x(0)=0$, we may assume $x'(0)>0$.

First consider the case $x_0=x(0)\geqq 0$, $v_0=x'(0)>0$ (the remaining case being $x_0=x(0)>0$, $v_0=x'(0)\leqq 0$).

In the (x, v)-plane, $x=x(t)$, $v=v(t)$ satisfy

$$\frac{dv}{dx} = -\frac{x}{v}(v^2+f(x)) \tag{2}$$

wherein $v=x'$. Let $A(x, v)=F(x)+v^2/2$. Since $F(x)\to\infty$ as $x\to\infty$ it follows that for each real $c>0$, $A(x, v)=c$ is a simple closed curve symmetric with respect to both the x-axis and v-axis in the (x, y)-plane. Moreover, since $-x(t)$ satisfies (1) if $x(t)$ satisfies (1), any integral curve of (2) is symmetric about the v-axis and it is closed if it cuts the positive v-axis and also cuts the negative v-axis.

Consider $P(x_0, v_0)$ in the (x, v)-plane and let C be the corresponding integral curve of (2) through P. So long as $x>0$, $v>0$, C has negative slope hence cannot turn toward the only singular point, (0, 0). On the other hand,

$$dA/dt = -xv^3 < 0$$

on C hence C lies within the curve $A(x, v)=F(x_0)+v_0^2/2$. According to the Poincaré-Bendixson Theorem, C cuts the x-axis at some point $x=a$, $v=0$ with $0<a<\alpha$ where $F(\alpha)=F(x_0)+v_0^2/2$.

Suppose that this occurs for $t=t_1>0$. That is, $x(t_1)=a>0$, $x'(t_1)=0$, $x''(t_1)=-af(a)<0$. We now require that for some $t_2>t_1$, $x(t_2)=0$ and $v(t)=x'(t)<0$ for $t_1<t\leqq t_2$. It is clear that, other conditions satisfied, $v(t_2)=x'(t_2)<0$ because $dA/dt>0$ in quadrant IV hence C can not turn toward the singularity (0, 0).

Now, considering $x=x(t)$ in the (t, x)-plane we have $x(t_1)>0$ and, by continuity, $x(t)>0$ for $t>t_1$ unless $x(t)$ has the desired zero beyond t_1. It is clear that if there is no $t_2>t_1$ for which $x(t_2)=0$, then for all $t>t_1$, $x'(t)=v(t)<0$ since $dv/dt>0$ on C until $x=0$ and since $x''(t)<0$ until $x=0$. The combination $x(t)>0$, $x'(t)<0$, $x''(t)<0$ for all real $t>t_1$ is impossible as is seen by an application of the mean-value theorem [2]. Thus there must be a $t=t_2$ for which $x(t_2)=0$ and C meets the negative v-axis.

If $x_0=0$, then this case of the proof is finished. If the initial conditions were $x_0>0$ (and, of course, $v_0>0$) then C must be continued through the quadrants III and then II to meet the positive v-axis. In quadrant III this is done as in quadrant I by the Poincaré-Bendixson Theorem. The continuation in quadrant II is done as in quadrant IV to secure the intersection on the positive v-axis. Continuing to P is automatic since the integral curves are symmetric with respect to the v-axis.

Finally, if one has initial conditions $x_0>0$, $v_0\leqq 0$ one follows C across the

negative v-axis and through quadrants III and II, as before, to secure an intersection on the positive v-axis. This completes the proof.

The proof given for Theorem 1 may be used to yield the same theorem for the equation

$$x'' + h(x)g(x') + h(x)f(x) = 0$$

if $g(x')$ is an even function, $g(x')>0$ for $x'>0$, $h(x)$ is an odd integrable function, $h(x)>0$ for $x>0$, and $f(x)$ is as above. One now takes

$$A(x, v) = \int_0^x h(u)f(u)du + v^2/2.$$

The solutions of the equation

$$x'' - xx'^2 - x^3 = 0, \qquad x' = dx/dt,$$

are eventually monotone as is clear from the following theorem.

THEOREM 2. *In the equation*

$$x'' = xF(x, x') \tag{3}$$

assume that $F(x, x')>0$ *for* $x^2+x'^2\neq 0$ *and that solutions of the equation are unique. If* $x=x(t)$, $x(t)\not\equiv 0$, *is a solution of* (3) *valid for all* $t\geqq t_0$, *then* $x(t)$ *is eventually monotone. If* $x(t)$ *has a zero, then* $x(t)\to\infty$ *or* $x(t)\to-\infty$.

Proof. Suppose that for some $t_1\geqq t_0$, $x(t_1)=0$. Since $x(t)\not\equiv 0$ and solutions are unique, $x'(t_1)\neq 0$. If $x'(t_1)>0$, it is clear that $x'(t)>0$ for all $t\geqq t_1$ since $x''(t)>0$ so long as $x>0$. Thus, for all $t>t_1$, $x(t)>0$, $x'(t)>0$ and $x''(t)>0$. Hence $x(t)\to\infty$ unless $x(t)\to c<\infty$. The latter case is impossible by the mean value theorem [2].

If $x'(t_1)<0$, then $x'(t)<0$ for all $t\geqq t_1$ since $x''(t)<0$ so long as $x(t)<0$. Thus, for all $t>t_1$, $x(t)<0$, $x'(t)<0$ and $x''(t)<0$. Hence $x(t)\to-\infty$ unless $x(t)\to c>-\infty$. The latter case is again impossible.

Suppose that $x(t)=0$ for $t\geqq t_0$. If $x(t_0)>0$, then $x'(t_0)>0$ implies $x'(t)>0$ for all $t>t_0$ since $x''(t)>0$ and $x(t)\to\infty$ as $t\to\infty$. If $x'(t_0)<0$, then either $x'(t)\leqq 0$ for all $t\geqq t_0$ or, in case $x'(t)$ changes sign, $x'(t)>0$ for all large t and $x(t)\to\infty$ as $t\to\infty$. At most one change of sign is possible for $x'(t)$ for $t>t_0$ since $x''(t)>0$ for all $t\geqq t_0$. In either case, $x(t)$ is eventually monotone.

Similarly, if $x(t_0)<0$, then $x''(t_0)<0$. If $x'(t_0)\leqq 0$, then $x(t)\to-\infty$ as $t\to\infty$. If $x'(t_0)>0$, then either $x'(t_0)\geqq 0$ for all $t\geqq t_0$ or, again, $x'(t)$ may have one zero after which $x'(t)<0$ and $x(t)\to-\infty$. In all cases $x(t)$ is eventually monotone and the theorem is proved.

The behavior of solutions of

$$x'' - xx'^2 + q^2x^3 = 0, \quad \text{and} \tag{4}$$

$$x'' + xx'^2 - q^2x^3 = 0 \tag{5}$$

is not as easily established. As a clue to what may happen we notice that (4) is satisfied by $x=\pm\sinh qt$ and (5) is satisfied by $x=\pm\cosh qt$.

NEAR-HOMOGENEITY ON 2-MANIFOLDS

H. C. WISER, Washington State University

The concept of continuous near-homogeneity was introduced in [5]. In this note, this and other related types of homogeneity are considered as applied to proper subcontinua of a 2-manifold. A space X is said to be *near-homogeneous* if for each $x\in X$ and each open set U in X there is a homeomorphism h of X onto itself such that $h(x)\in U$. If for each x and U there is an isotopy H_t of X onto itself such that $H_1(x)\in U$, the space is said to be *continuously near-homogeneous*. In the following, $H(X)$ will be the isotopy path of X under the isotopy H_t. A space X is *locally homogeneous* if for each two points x and y of X there are neighborhoods U_x and U_y and a homeomorphism h on U_x such that $h(U_x)=U_y$ and $h(x)=y$.

LEMMA 1. *If H_t is an isotopy of a simple triod T which moves the branch point of T, then $H(T)$ contains a simple closed curve.*

Proof. Since $H(T)$ is the continuous image of a locally connected set it must be locally connected. Suppose $H(T)$ contains no simple closed curve, i.e., $H(T)$ is a dendrite. Let b be the branch point of T, and A the unique arc from $H_0(b)$ to $H_1(b)$. There are uncountably many values of t in $[0, 1]$ such that the corresponding points $H_t(b)$ are disjoint points of A, branch points of $H_t(T)$, and thus branch points of the dendrite—a contradiction.

THEOREM 1. *No continuously near-homogeneous proper subcontinuum X of a 2-manifold M contains a simple triod.*

Proof. Suppose X contains a triod T. Let $p\in X-T$ (since T is clearly not continuously near-homogeneous) and D a disk on M containing p and not intersecting T. There is an isotopy h of X onto itself which carries the branch point of T into D and thus an isotopy H_t and a triod T_1 in $h(T)$ such that $H(T_1)$ lies entirely in D and $H_0(b)\neq H_1(b)$ where b is the branch point of T_1. By Lemma 1 there is a simple closed curve J in $D\cap X$ and since $X\neq J$ there is an isotopy g_t of J such that $g(J)\subset D$ and $g_1(J)\neq J$. As in Theorem 10 of [5] such an isotopy would sweep through some disk in D and we are led to the contradiction that X is a 2-manifold without boundary.

COROLLARY 1. *A continuously near-homogeneous arcwise connected nondegenerate proper subcontinuum of a 2-manifold must be a simple closed curve.*

Proof. This is an immediate consequence of Theorem 1 above and Theorem 9 of [7].

THEOREM 2. *If X is a continuously near-homogeneous proper subcontinuum of a 2-manifold which contains a simple closed curve J, then X is a simple closed curve.*

Proof. Suppose $p \in X - J$ and U is an open set containing p such that $U \cap J = 0$. Let H be an isotopy on X such that $H_1(J) \cap U \neq 0$, then $H(J)$ must be a continuum filled with the simple closed curves $\{H_t(J)\}$ for $0 \leqq t \leqq 1$. Any two of these simple closed curves must be identical or fail to intersect since X contains no triod by Theorem 1. By Theorem 7 of [7], $H(J)$ must be an annulus or Möbius strip which contradicts Theorem 1.

COROLLARY 2. *If X is a locally connected continuously near-homogeneous nondegenerate proper subcontinuum of a 2-manifold, then X is a simple closed curve.*

Proof. By Corollary 2 of [5], X must contain a simple closed curve and the result follows from Theorem 2.

REMARK. In [1] R. H. Bing gives an example of a planar continuously near-homogeneous continuum which is not a simple closed curve. This continuum is also locally homogeneous.

THEOREM 3. *If a nondegenerate proper subcontinuum X of a 2-manifold is aposyndetic and continuously near-homogeneous then X is a simple closed curve.*

Proof. In Theorem 10 of [7] the analogous result for homogeneous continua is established. The properties of X in the proof of that theorem which depend on homogeneity are (1) X contains no simple triod, (2) if X contains a simple closed curve then it is a simple closed curve, and (3) X contains no separating point. For continuously near-homogeneous continua, these three properties are established by Theorem 1 and Theorem 2 above, and by Corollary 1 of [5]. With these substitutions one may proceed as in Theorem 10 of [7] to show that if X is not a simple closed curve then a component of the boundary of one of its complementary domains must be an arc which leads to a contradiction.

REMARK. A Sierpinski curve (i.e., a 2-sphere with a sequence of disjoint nontangent open disks removed such that the union of the disks is dense in the sphere) is near-homogeneous, locally connected, and contains a homeomorphic image of each 1-dimensional plane continuum. Thus continuously near-homogeneity cannot be replaced by near-homogeneity in Theorems 1, 2, and 3. Since the Sierpinski curve is also invertible [3], this condition (though stronger than near-homogeneity) cannot be substituted for continuous near-homogeneity. Of course continuous invertibility implies continuous near-homogeneity and thus can be substituted to give weaker versions of Theorems 1, 2, and 3. These theorems would have as corollaries some of the theorems of [4]. By removing disks from 2-manifolds other than the sphere we obtain other 1-dimensional near-

homogeneous continuous curves; one may show that such continua are non-planar by locating primitive skew curves in them.

The locally connected case of the following theorem is considered since the proof of the misstated Corollary 8.2 of [7] establishes the result only for continua which are not locally connected.

THEOREM 4. *No locally homogeneous proper subcontinuum X of a 2-manifold M contains a simple triod.*

Proof. By local homogeneity each point of X must be of the same order. Since all but a countable number of local separating points of X must be of order 2, either X is a simple closed curve or X has no local separating points. In the latter case local homogeneity may be substituted for homogeneity in the proof of Lemma 10.2 of [7] to show that the boundary of each complementary domain of X consists of a finite number of continuous curves. Let B_i be a component of the boundary of a complementary domain D_i. If B_i contains no simple closed curve it must be a dendrite which leads to a contradiction. Suppose B_i contains a simple closed curve J and $B_i \neq J$ then B_i contains a simple triod T with branch point b. Since X is locally connected and has no local separating point we may use a result of F. B. Jones' [6] to get a connected open set D in X which contains b but not the end points of T, lies on a disk in M, and has a connected boundary. Let x, y, and z be the endpoints of T. Then there are continua K_1 and K_2 in the boundary of D such that K_1 is irreducible from the arc bx to by and K_2 is irreducible from by to bz. But since x, y, z are on the boundary of D_i the continua K_1 and K_2 prevent some points near b from being boundary points of D_i. Thus B_i is a simple closed curve.

If each point of X is on the boundary of some complementary domain, X is the union of a countable number of simple closed curves. Then by a Baire theorem some one of them contains an open set and thus a local separating point. Since we have assumed that X has no local separating points, some point q of X must fail to lie on the boundary of a complementary domain. Each point a of an arc A in X must be the branch point of some simple triod $T(a)$. Let h_a be a homeomorphism from a canonical simple triod T onto $T(a)$. The set $B = \{T(a)/a \in A\}$ becomes a separable metric space under the metric $d(T(a), T(b)) = \max_{t \in T} (h_a(T), h_b(T))$. In this metric there is some sequence of triods in B converging to a triod in B and thus a sequence of disjoint arcs converging to an arc C (details of such an argument may be found in [1]). On C one may choose a disk neighborhood D and, using the local connectedness of X and the arcs of X converging to C, find a simple closed curve J_1 in $X \cap D$. The interior of J_1 relative to D must contain some complementary domain of X with boundary J. Choosing $p \in J$ and using local homogeneity just as in the proof of Theorem 1 in [2] we find that having p on the boundary of a disk in the complementary domain and q not on the boundary of a complementary domain leads to a contradiction.

The analog of Corollary 1 for locally homogeneous continua now follows from Theorem 4. To establish the analog of Theorem 3 one need only show that a

locally homogeneous proper subcontinuum of a 2-manifold is a simple closed curve if it contains a simple closed curve.

I wish to thank Professor C. E. Burgess for calling my attention to F. B. Jones' result.

THE INTERVAL TOPOLOGY AND ORDER CONVERGENCE AS DUAL CONVERGENCE STRUCTURES

D. C. KENT, Washington State University

In a partially ordered set $(S, \leqq)$, the *interval topology* is defined by taking for a closed subbase all sets of the form x^+ and x^*, all x in S, where x^+ and x^* denote respectively the set of all lower and upper bounds of x. (For a subset A of S, A^+ and A^* denote likewise the lower and upper bounds of A.) A filter $\mathfrak{F}$ on S *order-converges* to x if $\inf \mathfrak{F}^* = \sup \mathfrak{F}^+ = x$, where $\mathfrak{F}^+ = (\cup F^+: F \text{ in } \mathfrak{F})$ and $\mathfrak{F}^* = (\cup F^*: F \text{ in } \mathfrak{F})$. The reader is referred to [1], [4], and [5] for additional information about these concepts.

A convergence γ on a set S is called a convergence structure if: (1) For each x in S, the ultrafilter x^0 generated by x γ-converges to x, and (2) if $\mathfrak{F}$ γ-converges to x and $\mathfrak{G} \supset \mathfrak{F}$ then $\mathfrak{G}$ γ-converges to x. Order convergence is a convergence structure on any partially ordered set $(S, \leqq)$, and, needless to say, each topology defines a convergence structure. A convergence structure γ is *topological* if γ-convergence of filters coincides with convergence under some topology t. If γ and δ are convergence structures on S, then γ is *finer* than δ if a filter δ-converges to a point whenever it γ-converges to that point.

We shall now suppress all order properties of $\leqq$, regarding it as an arbitrary relation on S. If $A \subset S$ and $\mathfrak{F}$ is a filter on S, then A^*, A^+, $\mathfrak{F}^*$, $\mathfrak{F}^+$ are still meaningful in this weaker structure. (For instance, $A^* = \{x \text{ in } S: y \leqq x, \text{ all } y \text{ in } A\}$.)

DEFINITION 1. (1) *A filter $\mathfrak{F}$ on S q-converges to x if $\mathfrak{F}^{*+} \subset x^+$ and $\mathfrak{F}^{+*} \subset x^*$.*

(2) *A filter $\mathfrak{G}$ on S p-converges to x if, for each ultrafilter $\mathfrak{F} \supset \mathfrak{G}$, $\mathfrak{F}^{+*} \supset x^*$ and $\mathfrak{F}^{*+} \supset x^+$.*

THEOREM 1. (1) *The relation $\leqq$ on S is reflexive if and only if q is a convergence*

structure. (2) *The relation* $\leqq$ *on* S *is transitive if and only if* p *is a convergence structure.*

Proof. In order for $\leqq$ to be reflexive (transitive) it is necessary and sufficient that, for each x in S, $x^{+*} \subset x^*$ and $x^{*+} \subset x^+$ ($x^{+*} \supset x^*$ and $x^{*+} \supset x^+$). It is clear that $(x^0)^{+*} = x^{+*}$ and $(x^0)^{*+} = x^{*+}$. Thus the statements "x^0 q-converges to x, all x in S" and "x^0 p-converges to x, all x in S," respectively, are equivalent to the statements "$\leqq$ is reflexive" and "$\leqq$ is transitive," respectively. Next, assume that $\mathfrak{F}$ q-converges to x. If $\mathfrak{G} \supset \mathfrak{F}$, then $\mathfrak{G}^{+*} \subset \mathfrak{F}^{+*}$ and $\mathfrak{G}^{*+} \subset \mathfrak{F}^{*+}$, and thus $\mathfrak{G}$ q-converges to x. The second condition for being a convergence structure is automatically satisfied by p-convergence.

THEOREM 2. (1) *If* $\leqq$ *is transitive and reflexive, then* p *is topological, and the corresponding topology* t *has a closed subbase of sets of the form* x^+ *and* x^*, x *in* S. (2) *The convergence structure* q *is finer than* p.

Proof. (1) If $\mathfrak{F}$ is an ultrafilter on S which converges to x with respect to the topology t described above, and y is not in x^+, then the complement of y^* is in $\mathfrak{F}$. Thus y is not in $\mathfrak{F}^{*+}$, and $x^+ \supset \mathfrak{F}^{*+}$. Similarly, $x^* \supset \mathfrak{F}^{+*}$, and $\mathfrak{F}$ p-converges to x. This reasoning is reversible. (2) Let $\mathfrak{F}$ q-converge to x; $\mathfrak{G} \supset \mathfrak{F}$. Then $\mathfrak{G}^{*+} \subset x^+$. If y is in x^+, then y is a lower bound of x^*, hence of $\mathfrak{G}^{+*}$, and hence of $\mathfrak{G}^*$. Thus $x^+ = \mathfrak{G}^{*+}$. Similarly, $x^* = \mathfrak{G}^{+*}$, and $\mathfrak{G}$ p-converges to x. It follows that $\mathfrak{F}$ p-converges to x.

THEOREM 3. *If* $(S, \leqq)$ *is a partially ordered set, then* q *coincides with order convergence.*

Proof. Let $\mathfrak{F}$ order-converge to x. Since $x = \sup \mathfrak{F}^+$, each upper bound of $\mathfrak{F}^+$ is an upper bound of x, and hence $\mathfrak{F}^{+*} \subset x^*$. Also, $\mathfrak{F}^{*+} \subset x^+$, and $\mathfrak{F}$ q-converges to x. Conversely, let $\mathfrak{F}$ q-converge to x. Then $\mathfrak{F}^+ \subset \mathfrak{F}^{*+} \subset x^+$. If y is an upper bound of $\mathfrak{F}^+$, then y is in x^*, and thus $x = \sup \mathfrak{F}^+$. Similarly, $x = \inf \mathfrak{F}^*$, and $\mathfrak{F}$ order-converges to x.

We have exhibited a fundamental duality between the interval topology and the order convergence in a partially ordered set which is not at all apparent from the standard definitions of these concepts.

If $\leqq$ is an equivalence relation, then q is topological; the corresponding topology has for an open base the set of equivalence classes relative to $\leqq$. When $\leqq$ is a partial order relation, the problem of finding additional conditions on the order that make q topological is interesting and nontrivial. The only solutions (other than a chain or product of chains) known to me are found in [2] and [3].

CLASSROOM NOTES

POWER SERIES SOLUTIONS OF ORDINARY DIFFERENTIAL EQUATIONS

JOHN W. DETTMAN, Oakland University

It has become rather common in elementary books on ordinary differential equations to prove at least one existence and uniqueness theorem for the initial value problem for a first order equation. It is much less common to find such theorems proved for higher order equations, because the usual procedure is to put the problem in the form of a system, and the students usually do not have the linear algebra required to cope with systems. For the applications, higher order linear equations are very important. The existence and uniqueness theorem for these can be handled as easily as for the first order equation if a Green's function is introduced and the problem is cast in the form of a Volterra integral equation. For example, the initial value problem $y''+q(t)y=0$, $y(0)=c_0$, $y'(0)=c_1$, is equivalent to $y=c_0+c_1t+\int_0^t(\tau-t)q(\tau)y(\tau)d\tau$. (The equation $y''+p(t)y'+q(t)y=0$ can be put into this form by first making the change of variable $y=vw$, where $v=\exp[-\frac{1}{2}\int_0^t p(\tau)d\tau]$.) The Green's function, in this case is $G(\tau, t)=\tau-t$. Using successive approximations, it is easy to prove the following theorem:

THEOREM 1. *If $q(t)$ is continuous for $|t|\leqq r$, the initial value problem $y''+qy=0$, $y(0)=c_0$, $y'(0)=c_1$ has a unique solution valid for $|t|\leqq r$.*

For the purpose of computation it is useful to have various representations of the solution to the initial value problem. One of the most important is the power series representation. It is well known that we have the following theorem:

THEOREM 2. *If $q(t)$ has a power series representation valid for $|t|<R$, then the solution to $y''+qy=0$, $y(0)=c_0$, $y'(0)=c_1$ has a power series representation valid in the same interval.*

The purpose of this note is to give a simple proof of Theorem 2, which should be readily understood by sophomores who have had a good course in calculus including infinite series. This theorem is usually proved using complex variables, Cauchy inequalities, etc., techniques which are not usually available to sophomores. In [1] Coddington proves the theorem without complex variables but the proof involves rather elaborate juggling of inequalities. The present proof makes use of the sequence of successive approximating functions $y_n(t)$ which were shown in the proof of Theorem 1 to converge uniformly to the solution $y(t)$. It is a simple matter to show that each $y_n(t)$ has a power series expansion which agrees to $2n+1$ terms with the formal power series for $y(t)$. Using this we can show that the formal series actually converges.

Since $q(t)$ has a power series representation $q_0+q_1t+q_2t^2+\cdots$ for $|t|<R$, we may differentiate it at $t=0$ as many times as we like and hence we can obtain

the coefficients for the formal power series for $y(t)$, i.e., $y(0)=c_0$, $y'(0)=c_1$, $c_2=y''(0)/2!=-\frac{1}{2}c_0q_0$, $c_3=y'''(0)/3!=-\frac{1}{6}(c_0q_1+c_1q_0)$, etc. The only problem is to show that $c_0+c_1t+c_2t^2+\cdots$ converges for $|t|<R$.

In proving Theorem 1, we shall have introduced successive approximations, $y_0=c_0+c_1t$, and for $n=1, 2, 3, \cdots$

$$y_n(t) = c_0 + c_1t + \int_0^t (\tau - t)q(\tau)y_{n-1}(\tau)d\tau.$$

and shall have shown that $y_n(t)$ converges uniformly to $y(t)$, the unique solution, for $|t|\leqq r<R$. Now it is easy to show that $y_n(t)$ has a power series representation for $|t|<R$. This is a simple induction in which one forms the Cauchy product of y_{n-1} and q and integrates term by term.

We also can show that for $n=1, 2, 3, \cdots$ the power series for y_n agrees with the formal series for y up to $2n+1$ terms. This is because y_n satisfies $y_n''=-qy_{n-1}$, $y_n(0)=c_0$, $y_n'(0)=c_1$ and therefore its derivatives at $t=0$ up to the $2n$-th are the same as those for y.

For the next step of the proof we need the following simple lemma about power series with positive coefficients:

LEMMA. *If* $f(t)=a_0+a_1t+a_2t^2+\cdots$ *converges for* $|t|\leqq r$ *and* $a_n\geqq 0$ *for* $n=0, 1, 2, 3, \cdots$, *then* $a_n\leqq M/r^n$ *where* $M=\max f(t)$ *for* $|t|\leqq r$.

Proof. Since $a_n\geqq 0$ for all n, $M=\max f(t)=a_0+a_1r+a_2r^2+\cdots$. Hence $a_nr^n\leqq M$, and $a_n\leqq M/r^n$.

We first prove the expansion Theorem 2 for the special case of a $q(t)$ with all its coefficients negative, and it will turn out that the general case can be obtained from this special case. If all the coefficients of $q(t)$ are negative then $y_n(t)$ will have a power series representation with all its coefficients positive, provided c_0 and c_1 are positive. This is because

$$y_n(t) = c_0 + c_1t + \int_0^t (t - \tau)[-q(\tau)]y_{n-1}(\tau)d\tau$$

and the Cauchy products for $-qy_{n-1}$ will all have positive coefficients. Therefore, if

$$y_n(t) = a_{n0} + a_{n1}t + a_{n2}t^2 + \cdots$$

then $a_{nm}\leqq M_n/r^m$, where $M_n=\max y_n(t)$ for $|t|\leqq r<R$. Remembering that $y_n(t)$ converges uniformly to $y(t)$ on $|t|\leqq r$, where $y(t)$ is continuous, we see that the M_n are bounded. Hence, there exists M independent of n such that $a_{nm}\leqq M/r^m$. Thus $a_{mm}\leqq M/r^m$, and $c_m=a_{mm}$, hence $c_m\leqq M/r^m$. Now $|c_mt^m|\leqq M(|t|/r)^m$ and, therefore, the formal series converges for $|t|<r$. But r is *any* number satisfying $0<r<R$. Hence, the formal series converges for $|t|<R$.

Finally, for the general case, consider $|t|\leqq r<R$. Since $q_0+q_1t+q_2t^2+\cdots$

converges absolutely for $t=r$, there exists a K such that $|q_n| \leqq K/r^n$. Consider the problem

$$Y'' - (K + Kt/r + Kt^2/r^2 + \cdots)Y = Y'' - Kr/(r-t)Y = 0,$$
$$Y(0) = C_0 = |c_0|, \quad Y'(0) = C_1 = |c_1|.$$

By the above discussion, Y has a power series representation $C_0+C_1t+C_2t^2+\cdots$ for $|t|<r$. It is easily seen by comparison, that $c_0+c_1t+c_2t^2+\cdots$ converges for $|t|<r$, since $|c_0|=C_0$, $|c_1|=C_1$, $|c_2|=\frac{1}{2}|c_0q_0| \leqq \frac{1}{2}C_0K=C_2$, $|c_3|=\frac{1}{6}|c_0q_1+c_1q_0| \leqq \frac{1}{6}(C_0K/r+C_1K)=C_3$, etc. Therefore, since r is *any* number satisfying $0<r<R$, the power series representation of y converges for $|t|<R$.

The reader will recognize that Theorem 2 holds because $t=0$ is an *ordinary point* of the differential equation. Nevertheless, the same method of proof will work for the corresponding convergence theorem for the modified power series expansion of solutions near a regular singular point (see [2]).

The method of proof presented here can easily be extended to higher order equations. The linear equation of order n can be put in the form of an integral equation, using a Green's function which is the unique solution of an initial value problem of order $n-1$. Hence the existence and uniqueness theorem and the power series representation can be established by induction.

MATRIX OF FINITE GROUPS

C. F. HARDING, Douglas Aircraft Company

It is well known that the elements of a finite group may be represented by a set of matrices obeying the same rules of combination under matrix multiplication. It has never been shown, however, that such a set of matrices may be obtained by inspection directly from the group multiplication table. In this paper we do just that for the finite group composed of positive integers modulo a prime, with its extension to more complex groups being obvious.

THEOREM. *If a matrix $M(\alpha)$ is constructed from the multiplication table of the positive integers modulo a prime p by placing* 1 *where α appears and zeros elsewhere, then $R(\alpha)=M(1)M(\alpha)$ is isomorphic to the group and forms a representation.*

Proof. Let us assume a finite group made up of the integers modulo a prime p so that its elements are 1, 2, $\cdots$, $p-1$. Now construct a multiplication table with the elements given in order, as shown below for the case $p=7$.

(1)

	1	2	3	4	5	6
1	1	2	3	4	5	6
2	2	4	6	1	3	5
3	3	6	2	5	1	4
4	4	1	5	2	6	3
5	5	3	1	6	4	2
6	6	5	4	3	2	1

If we take three elements $ij=k$, define the matrices $M(i)$, $M(j)$, and $M(k)$ by putting 1 wherever i, j, or k appear in the table while leaving zeros elsewhere. It should be clear from simple group algebra that each matrix has one and only one nonzero entry for either a row or a column; for example $M(5)$

(2)
$$\begin{bmatrix} 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \end{bmatrix}$$

In particular the locations (row x_i, column y_i) for $M(i)$ must be and are the only ones satisfying (3) below

(3) $$x_i y_i \equiv i \pmod{p}.$$

By a similar argument the locations of $M(j)$ are fixed by the y_i which satisfy (4) as x_j ranges over $1, 2, \cdots, p-1$.

(4) $$x_j y_j \equiv j \pmod{p};$$

we now define by $M(1)$ that special matrix such that y_1 is the inverse of x_1

(5) $$x_1 y_1 \equiv 1 \pmod{p}.$$

At this point multiply the above equations in the specified order so as to obtain the composite

(6)
$$\begin{aligned} x_i y_i x_1 y_1 x_j y_j &\equiv i \cdot 1 \cdot j \pmod{p} \\ &\equiv k \pmod{p}. \end{aligned}$$

If it is true that $R(i)R(j)=R(ij)=R(k)$ then

(7) $$M(k) = M(i)M(1)M(j).$$

As we are interested in the product $M(i)M(1)M(j)$ one can choose a specific x_i;

then, to find the column y_1 for $M(i)M(1)$, we obtain the equality

$$y_i = x_1. \tag{8}$$

By the same procedure we multiply $M(i)M(1)$, whose row and column of concern are x_iy_1, by $M(j)$ and get for the final column y_j, since it must be that

$$y_1 = x_j. \tag{9}$$

The equation (6) now reads as follows (10) telling us that the rows and columns of $M(k)$ are x_i, y_j:

$$x_iy_j \equiv k \pmod{p}. \tag{10}$$

Hence we can define a set of matrices $R(\alpha) = M(1)M(\alpha)$, for each α, which obey all the rules of the original group in a one-to-one correspondence (thus giving the desired representation) and where $R(1)$ is the identity; in fact the unit matrix.

GENERALIZED LEMMAS OF THE CALCULUS OF VARIATIONS

N. X. VINH, University of Colorado

In [1], Akhiezer gives a generalized version of the second fundamental lemma of the calculus of variations [2]. Using the same line of derivation this note generalizes to systems both of the fundamental lemmas.

Consider a real n-vector function

$$M(x) = [M_1(x), M_2(x), \cdots, M_n(x)], \quad x_1 \leqq x \leqq x_2 \tag{1}$$

and an arbitrary real n-vector function

$$\eta(x) = [\eta_1(x), \eta_2(x), \cdots, \eta_n(x)], \quad x_1 \leqq x \leqq x_2. \tag{2}$$

Let

$$(M, \eta) = \int_{x_1}^{x_2} \sum_{i=1}^{n} M_i(x)\eta_i(x)dx \tag{3}$$

then:

LEMMA I. *If $M(x)$ is continuous on the interval $[x_1, x_2]$ and if the equation*

$$(M, \eta) = 0 \tag{4}$$

holds for any arbitrary vector function $\eta(x)$ which belongs to the class C^m and which vanishes together with all its derivatives up to and including those of order k, $k \leqq m$, at the endpoints of $[x_1, x_2]$, then $M(x) \equiv 0$.

Proof. Suppose to the contrary that $M(x)$ does not vanish at a point $\bar{x}$ in $[x_1, x_2]$. Let $M_p(x)$ be a nonvanishing component of $M(x)$ at that point. By continuity there exists some interval $[a, b] \subset [x_1, x_2]$ in which $M_p(x)$ never vanishes. We consider the particular vector $\eta(x)$ such that

$$\eta_p(x) = 0 \text{ outside the interval } [a, b]$$
$$\eta_p(x) = [(x - a)(b - x)]^{m+1} \quad \text{for } a \leqq x \leqq b$$

and all the other components of $\eta(x)$ are identically zero on $[x_1, x_2]$. Then

$$(M, \eta) = \int_a^b M_p(x)[(x - a)(b - x)]^{m+1}dx \neq 0. \tag{5}$$

Inequality (5) contradicts assumption (4). Hence $M(x) \equiv 0$.

LEMMA II. *Let*

$$\phi_i(x) = [\phi_{i1}(x), \phi_{i2}(x), \cdots, \phi_{in}(x)], \quad i = 1, 2, \cdots, n \tag{6}$$

be n linearly independent vector functions, continuous on the interval $[x_1, x_2]$. *If* $M(x)$ *is a piecewise continuous vector function such that*

$$(M, \eta) = 0 \tag{7}$$

for all vector functions $\eta(x)$ *satisfying*

$$(\eta, \phi_i) = 0, \quad i = 1, 2, \cdots, n \tag{8}$$

then there exists a unique constant vector C such that at every point at which $M(x)$ *is continuous*

$$M(x) = \Phi'(x)C \tag{9}$$

where Φ' *is the transpose of the matrix formed by the vectors* ϕ_i.

Proof. Let

$$M(x) - \Phi'(x)C = \eta_0(x). \tag{10}$$

We shall prove that there exists a unique constant vector C such that $\eta_0(x)$ defined by (10) will satisfy (8). This requires that

$$C_1(\phi_i, \phi_1) + C_2(\phi_i, \phi_2) + \cdots + C_n(\phi_i, \phi_n) = (M, \phi_i), \quad i = 1, 2, \cdots, n. \tag{11}$$

The determinant of the linear system (11) in the C_i is the Gram determinant of the system (6) and is nonvanishing [1]. Hence C is uniquely determined and the vector $\eta_0(x)$ thus obtained, satisfies (8). Therefore we can use $\eta_0(x)$ in (7). Next, we have

$$\begin{aligned}(M - \Phi'C, M - \Phi'C) &= (M - \Phi'C, \eta_0) \\ &= (M, \eta_0) - \sum_{i=1}^{n} C_i(\eta_0, \phi_i) = 0.\end{aligned} \tag{12}$$

The integrand in the integral on the left is nonnegative. Hence, it follows from equation (12) that at every point at which $M(x)$ is continuous

$$M = \Phi'C.$$

It is obvious that this lemma includes the generalized lemma derived in [1] for a scalar function $M(x)$.

I wish to thank the referee and the editor for suggesting modifications.

NONARCHIMEDEAN INTEGERS

G. H. MEISTERS, University of Colorado

Our terminology is that of McCoy [1], but we shall denote an ordered integral domain (defined on page 37 of [1]) by the ordered pair (D, P), where D denotes the integral domain under consideration and P denotes the set of "positive" elements of D which satisfies the trichotomy law and is closed under addition and multiplication.

In McCoy's treatment the integers are characterized as an ordered integral domain with the property that the set of all positive elements is well-ordered (cf. [1], pp. 39–41). Then, if (D, P) is the domain of integers, the fact that P is well-ordered is used to prove (on p. 49 of [1]) the

DIVISION ALGORITHM. *$a \in D$ and $b \in P$ implies there exist unique elements q and r in D such that $a = bq + r$ and $0 \leqq r < b$.*

In this note we answer the following rather natural

QUESTION. If (D, P) is any ordered integral domain which satisfies the Division Algorithm, does it necessarily follow that P is well-ordered? And if not, what can be said about such an ordered integral domain?

That the answer to the first part of the question is "no" can be seen by an example such as the following:

An example of a nonarchimedean ordered integral domain which satisfies the division algorithm: Let D denote the integral domain of all polynomials in x over the field of rational numbers which have integral constant term. Let P denote those members of D whose leading coefficient is positive (in the usual sense). P is not well-ordered since elements of the form $x - n$ (for $n = 0, 1, 2, \cdots$) are in P and the set S of all polynomials of this type has no least member. Proof that this ordered integral domain satisfies the above Division Algorithm is as follows. Let $a(x)$ be a member of D and $b(x)$ a member of P. Then, in particular, $a(x)$ and $b(x)$ belong to $F[x]$, where F is the field of rational numbers, and so (cf. [1] 8.16, p. 135) there exist unique polynomials $q'(x)$ and $r'(x)$ in $F[x]$ such that

$$a(x) = b(x)\cdot q'(x) + r'(x) \tag{1}$$

and $r'(x)=0$ or $\deg r'(x)<\deg b(x)$. If the constant term q'_0 of $q'(x)$ is an integer and the leading coefficient of $r'(x)$ is negative, let $s=1$. Otherwise let s denote the unique rational number satisfying $0\leqq s<1$ such that q'_0-s is an integer. Then equation (1) can be written in the form

$$a(x) = b(x)\cdot[q'(x) - s] + s\cdot b(x) + r'(x). \tag{2}$$

Thus if we denote $q'(x)-s$ by $q(x)$ and $s\cdot b(x)+r'(x)$ by $r(x)$ we obtain $a(x)=b(x)\cdot q(x)+r(x)$ and $0\leqq r(x)<b(x)$, where $q(x)$ and $r(x)$ belong to D. Furthermore, $q(x)$ and $r(x)$ satisfying these conditions are seen to be uniquely determined.

Thus in order to characterize the integers, the property that P be well-ordered cannot be replaced by the Division Algorithm. The following simple results show, however, that ordered integral domains which satisfy the Division Algorithm (but without a well-ordered P) have some properties in common with the integers (such as Corollaries 1 and 2 below) and can be characterized as "nonarchimedean."

THEOREM. *If (D, P) is an ordered integral domain satisfying the Division Algorithm and if p is a member of P which is not a positive "integer," me, then $me<p$ for all integers m.* (Here e denotes the multiplicative identity of D.)

Proof. Let S denote the set of positive integers m such that $p<me$. If S is not empty, then S contains a least member, say n. Thus $(n-1)e<p<ne$. But then $0<p-ne+e<e$. If q denotes $p-ne+e$, we obtain

(i) $0=e\cdot 0+0$ with $0\leqq 0<e$, and (ii) $0=e\cdot(-q)+q$ with $0\leqq q<e$, which contradicts the uniqueness requirement of the Division Algorithm. Hence S must be empty.

COROLLARY 1. *If (D, P) is an ordered integral domain satisfying the Division Algorithm, then D contains no member between 0 and e.*

Proof. If $0<p<e$, then p is not of the form me for any positive integer m (because $me\geqq e$). Hence, by the above theorem $p>me$ for all integers m and thus, in particular $p>e$ contrary to hypothesis.

COROLLARY 2. *If (D, P) is an ordered integral domain satisfying the Division Algorithm, then no member of D other than e and $-e$ can possess a multiplicative inverse.*

Proof. Suppose $xy=e$, $x\neq e$ and $x\neq -e$. Then $|x|\cdot|y|=e$ and $|x|\neq e$ implies $|x|>e$. But this implies $|x|\cdot|y|>e\cdot|y|>0$ or $e>|y|>0$, contrary to Corollary 1.

DEFINITION. *An ordered integral domain (D, P) is said to be archimedean if for each element a in D and each element b in P there exists an integer n such that $nb>a$.*

COROLLARY 3. *An ordered integral domain (D, P) satisfying the Division Algorithm is isomorphic to the domain of integers if and only if (D, P) is archimedean.*

Proof. Direct consequence of the above theorem.

Thus the example described above is a nonarchimedean ordered integral domain which nevertheless satisfies the Division Algorithm, and consequently could be considered a system of "nonarchimedean integers."

REMARKS ON A SECOND ORDER DIFFERENTIAL EQUATION

J. P. Hoyt, U. S. Naval Academy

The differential equation: $xd^2y/dx^2-(x+n)dy/dx+ny=0$, n a nonnegative integer, has some interesting properties which make it very handy in teaching elementary differential equations. Some of these properties are:

1. Although, for $n>0$, it has a regular singular point at $x=0$, it is satisfied by $y=e^x$ for all values of n (no restriction here), i.e. it is satisfied by a simple series solution.

2. It is satisfied by a polynomial consisting of the first $n+1$ terms of the Maclaurin expansion of e^x.

3. Its indicial equation has roots 0, and $n+1$. Although the two roots differ by an integer, the smaller root gives a general solution.

4. In solving the equation by the method of Frobenius, both the polynomial solution and a Frobenius type series solution are obtained by using the smaller root of the indicial equation. By some small manipulation the solution $y=e^x$ is then obtained.

5. It is easy to see that $y=e^x$ is a solution and then the substitution $y=ve^x$ can be easily used to reduce the order and discover a general solution.

Finally, with particular values substituted for n, the equation provides a good source of individual problems.

ON A FIXED-POINT THEOREM FOR METRIC SPACES

T. K. Hu, Southern Illinois University

Let X, Y be metric spaces. A mapping f: $X\to Y$ for which there exists r, $0<r<1$, such that $d(f(x), f(y))\leqq rd(x, y)$ for all $x, y\in X$ will be called a *contraction* and r a *contraction constant for* f. The following fixed-point theorem is well known: *Let X be a complete metric space; if S is a nonempty closed subset of X and f: $S\to S$ a contraction, then f has a unique fixed point.* Question: What are the most general metric spaces with this fixed-point property? The answer is easy:

Proposition. *Let X be a metric space. Then the following are equivalent:*
(1) *X is complete,*

(2) *If S is any nonempty closed subset of X and f: $S \to S$ any contraction, then f has a fixed point.*

Proof. We need only show that (2) implies (1). Suppose that X contains a nonconvergent Cauchy sequence $(x_n)_{n=0}^{\infty}$. Since $(x_n)_{n=0}^{\infty}$ has the Cauchy property, it has no cluster points, i.e., it has no convergent subsequence. Since, moreover, $\{x_n: n=0, 1, \cdots\}$ must be infinite, we may assume that it consists of distinct terms; otherwise, we may select a subsequence which does. Take any $x \in X$; then $l(x) = \inf\{d(x, x_n): x_n \neq x, n=0, 1, \cdots\} > 0$ because $(x_n)_{n=0}$ has no cluster points. Choose any r such that $0 < r < 1$. We define a mapping σ of the set of nonnegative integers into itself inductively as follows: $\sigma(0) = 0$; and if $n > 1$ and $\sigma(n-1)$ is defined, let $\sigma(n)$ be an integer $> \sigma(n-1)$ such that $d(x_i, x_j) \leqq rl(x_{\sigma(n-1)})$ for all integers $i, j \geqq \sigma(n)$. Then $(x_{\sigma(n)})_{n=0}^{\infty}$ is a subsequence of distinct terms and is nonconvergent. The set $S = \{x_{\sigma(n)}: n=0, 1, \cdots\}$ is closed and the mapping f: $S \to S$ defined by $f(x_{\sigma(n)}) = x_{\sigma(n+1)}$ for $n=0, 1, \cdots$, is a contraction with no fixed point. Our proof is therefore complete.

We remark that the result is not stated in the sharpest form: (2) may be weakened by replacing "closed subset" by "countably infinite closed subset" and by restricting our attention to contractions with a fixed contraction constant r.

PROBLEMS AND SOLUTIONS

EDITED BY E. P. STARKE

COLLABORATING EDITORS: J. BARLAZ, Rutgers—The State University; L. CARLITZ, Duke University; HASKELL COHEN, Louisiana State University; H. EVES, University of Maine; M. S. KLAMKIN, Ford Scientific Laboratory; R. C. LYNDON, University of Michigan; and A. WILANSKY, Lehigh University.

All problems (both elementary and advanced) proposed for inclusion in this Department should be sent to E. P. Starke, 1000 Kensington Ave., Plainfield, N. J. 07060. Proposers of problems are urged to enclose any solutions or information that will assist editors. Ordinarily, problems in well-known textbooks and results in generally accessible sources are not appropriate for this Department. No solutions (except those accompanying proposals) should be sent to Professor Starke.

ELEMENTARY PROBLEMS

Solutions of Elementary Problems should be sent to M. S. Klamkin, Ford Scientific Laboratory, P.O. Box 2053, Dearborn, Mich. 48121. To facilitate their consideration, solutions for Elementary Problems in this issue should be typed or written legibly on separate, signed sheets and should be mailed before August 31, 1967. Contributors (in the United States) who desire acknowledgment of receipt of their solutions are asked to enclose self-addressed stamped postcards.

Given n collinear points in a plane, what is the minimum possible number of intersections of semicircular arcs in the plane joining all nonadjacent pairs of points? What is the minimum number of intersections if simple curves are used instead of semicircles?

E 1979. *Proposed by R. T. Hood, Franklin College, Indiana*

Professor Euclides Paracelso Bombasto Umbuggio, who will be remembered by readers of this Department, has emerged from retirement. Having heard some of the recent discussion about the independence of the continuum hypothesis, he now appears in order to demolish it forever. To reach the widest possible audience, he has chosen the most elementary means of doing so: obviously, $1<\aleph_0$. Therefore, $\aleph_0<\aleph_0^{\aleph_0}$. Moreover, $\aleph_0<2^{\aleph_0}$. Therefore, $\aleph_0^{\aleph_0}<(2^{\aleph_0})^{\aleph_0}=2^{\aleph_0\cdot\aleph_0}=2^{\aleph_0}=c$. Therefore, $\aleph_0<\aleph_0^{\aleph_0}<c$.

Deflate the professor: demolish his demolishment!

E 1980. *Proposed by R. E. Chandler, Duke University*

The street plan for a certain town is a generalization of the tic-tac-toe board with n vertical streets and m horizontal streets (with no vertical street intersecting the end of a horizontal street and vice versa). An automobile will start at the end of one (unspecified) street and travel to the end of another. What is the minimum number of traffic counters (each to be placed in the middle of a block) necessary to determine the route of the automobile? The route is to have no cycles, and the counters record the time that the automobile passes so that the direction of the route is determined when two counters have been passed.

E 1981. *Proposed by M. V. Subbarao, University of Alberta*

Let b and k be given positive numbers, $k\leqq 1$, and let B be the union of the open intervals $|x-(4n+k)b| <b$ $(n=1, 2, \cdots)$. If A is a subset of B such that $x\in A$ implies $2x\in A$, show that $A=\{4b, 8b, 12b, \cdots\}$ if $k<1$ and A is null if $k=1$.

E 1982. *Proposed by J. S. Biggerstaff, Portland, Ore.*

A rational polygon is one whose sides, diagonals and area are all rational numbers. (1) Find sets of distinct rational triangles (not right-angled or isosceles) which have the same area; and (2) Find a pair of rational quadrilaterals (not parallelograms or trapezoids) which have the same area.

E 1983. *Proposed by Robert Spira, University of Tennessee*

Show that replicas of the 3×4 L-hexomino cannot be fitted to form a rectangle. (An L-hexomino is formed when straight lines are drawn joining the following points in order: (0, 0), (3, 0), (3, 1), (1, 1), (1, 4), (0, 4), (0, 0).)

E 1984. *Proposed by Erwin Just, Bronx Community College*

If the divisors of n are $d_1, d_2, \cdots, d_k$, prove that

$$\prod_{i=1}^{k} \phi(d_i) \leqq (n/k)^k.$$

SOLUTIONS OF ELEMENTARY PROBLEMS

Difference Equation

E 1837 [1965, 1129]. *Proposed by Yasuhiko Ikebe, University of Texas*

Solve the difference equation in two positive integers, m and n,

$$f(m, n) = n[f(m-1, n-1) + f(m-1, n)],$$

under the condition $f(m, n)=0$ if $m<n$, and $f(m, 1)=1$ for every m.

I. *Solution by M. T. L. Bizley, London, England.* Let $g(m, n)=f(m, n)/m!n!$ so that

$$mg(m, n) = g(m-1, n-1) + ng(m-1, n). \tag{1}$$

Since $g(m, n)=0$ for $m<n$, let

$$G \equiv G(x, y) = \sum_{m=0}^{\infty} \sum_{n=0}^{m} g(m, n)x^m y^n.$$

Then, $g(m, 1)=1/m!$ for all m implies, with the difference equation, that $g(m, 0)=0$ for all $m>0$. Hence we have from (1)

$$x\frac{\partial G}{\partial x} = xyG + x\left(y\frac{\partial G}{\partial y}\right),$$

$$\frac{1}{G}\frac{\partial G}{\partial x} = y\left\{1 + \frac{1}{G}\frac{\partial G}{\partial y}\right\},$$

$$\frac{\partial P}{\partial x} = y\frac{\partial P}{\partial y}, \qquad P = y + \log G.$$

Having regard to the boundary conditions $P=ye^x$, whence $G=e^{y(e^x-1)}$, which is

$$G=\sum_{n=0}^{\infty}\frac{1}{n!}y^n(e^x-1)^n.$$

Therefore $g(m, n)$ is the coefficient of x^m in

$$(e^x-1)^n/n!=\left(e^{nx}-\binom{n}{1}e^{(n-1)x}+\binom{n}{2}e^{(n-2)x}-\cdots\right)\Big/n!$$

which is

$$\frac{1}{n!}\left(\frac{n^m}{m!}-\binom{n}{1}\frac{(n-1)^m}{m!}+\binom{n}{2}\frac{(n-2)^m}{m!}-\cdots\right),$$

and hence

$$f(m, n)=g(m, n)m!n!=n^m-\binom{n}{1}(n-1)^m+\binom{n}{2}(n-2)^m-\cdots$$
$$+(-1)^{n-1}\binom{n}{n-1}1^m.$$

II. *Solution by C. A. Church, Jr. West Virginia University.* The recurrence, as given, is well known as that for $f(m, n)=\Delta^n 0^m$, the "differences of zero." The $f(m, n)$ are also known as the exponential numbers and have the exponential generating function $(e^x-1)^n$. If one divides the recurrence by $n!$ the result is the familiar recurrence for the Stirling numbers of the second kind. That is, in Riordan's notation, $S(m, n)=f(m, n)/n!=\Delta^n 0^m/n!$.

The results stated may be found in

J. Riordan, *An Introduction to Combinatorial Analysis*, New York, (1958), pp. 13, 33, 43.

C. Jordan, *Calculus of Finite Differences*, 2nd ed., New York, (1960), (Reprint), pp. 169, 613.

G. Boole, *The Calculus of Finite Differences*, 4th ed. (Reprint), pp. 28, 29.

This MONTHLY, 56 (1949), p. 347, problem 4276. (Note misprint in the last formula: the summation should be taken over $j=0, 1, \cdots, c-1$.)

Also solved by Anders Bager (Denmark), Sylvan Greene, M. S. Klamkin, D. A. Klarner, J. A. Lambert (Australia), D. C. B. Marsh, F. D. Parker, Walter Penney, Stanley Rabinowitz, and K. L. Yocom.

Bizley and Penney note that this solves the problem: Find the number of ways of placing m different objects into n different cells with no cell empty.

Two Triangle Inequalities

E 1838 [1965, 1129]. *Proposed by A. Oppenheim, University of Malaya, Kuala Lumpur*

Suppose that ABC is an acute-angled triangle: then

$$16\prod\cos^2 A+4\sum\cos^2 B\cos^2 C\leqq 1, \tag{1}$$

(2) $$4\sum \cos^2 B \cos^2 C \leqq \sum \cos^2 A.$$

Equality occurs when ABC is equilateral or right-angled isosceles and in no other case.

Solution by C. S. Venkataraman, Trichur, India. Let A' be the midpoint of BC; D the foot of the perpendicular from A upon BC; O the orthocenter; and R the circumradius of triangle ABC. We use the following three well-known results:

(i) $\Pi \cos A \leqq \frac{1}{8}$,

(ii) $\sum \cos^2 A = 1 - 2\Pi \cos A$,

(iii) $2R \cos B \cos C = OD$.

The angles A, B, C being acute implies that O lies inside the triangle ABC. Now from the triangle ODA', right-angled at D, we have $OD \leqq OA'$. It follows that the maximum value of OD is OA'. But when $OD = OA'$, the triangle OBC is isosceles with $OB = OC$, whence $AB = AC$. Hence from (iii) $2R \cos B \cos C$ is maximum when $AB = AC$. Similarly $2R \cos C \cos A$ is maximum when $BC = AB$. Then $AC = BC$ and $2R \cos A \cos B$ is also maximum, and triangle ABC is equilateral. Thus it follows that

$$\sum (2R \cos B \cos C)^2 \leqq \sum (2R \cdot \tfrac{1}{2} \cdot \tfrac{1}{2})^2 = 3R^2/4.$$

Therefore $4\sum \cos^2 B \cos^2 C \leqq \frac{3}{4}$. Using (i) this gives

$$16 \prod \cos^2 A + 4 \sum \cos^2 B \cos^2 C \leqq 16(1/64) + 3/4 = 1,$$

which is the required result (1).

Further (i) and (ii) imply

$$\sum \cos^2 A \geqq 1 - 2(1/8) = 3/4 \geqq 4 \sum \cos^2 B \cos^2 C,$$

which is result (2). Clearly, equality arises in both cases if and only if ABC is equilateral.

Triangle with Two Perpendicular Medians

E 1839 [1965, 1129]. *Proposed by Simeon Reich, The Hebrew Reali Secondary School, Haifa, Israel*

In the triangle ABC, m_b and m_c (the medians to the sides b and c) are perpendicular to each other. Prove $\cot B + \cot C \geqq \frac{2}{3}$.

I. *Solution by J. W. Baldwin, Wayne State University.* Let AD, BE, CF be the medians with $BE \perp CF$ at G, and $OD = DC = BD$. Draw $AK \perp BC$ at K. Then

$$\cot B + \cot C = \frac{BK + KC}{AK} = \frac{BC}{AK} \geqq \frac{BC}{AD} = \frac{2 \cdot GD}{3 \cdot GD} = \frac{2}{3}.$$

II. *Solution by Walter Bluger, Dominion Bureau of Standards, Ottawa.* The medians divide each other in the ratio 2:1. Let $m_c = 3$, $m_b = 3t$. Noting the right

triangles, we easily obtain

$$\cot B + \cot C = \frac{2t^2 - 1}{3t} + \frac{2 - t^2}{3t} = \frac{1}{3}(t + t^{-1}).$$

but the minimum of $t+t^{-1}$ is known to be 2 (when $t=1$ and the triangle is isosceles). Thus the proof is complete.

Also solved by A. N. Aheart, Ted Aldrich, Dov Avishalom (Israel), P. N. Bajaj, Merrill Barnebey, M. A. Bershad, D. A. Blaeuer, R. F. Brinker, M. J. Brown, John Burslem, C. R. Conniff, N. Ganesan (India), L. M. Geer, Richard Gisselquist, P. L. Gore, M. S. Greening (Australia), Louise S. Grinstein, J. D. Haggard, J. R. Hanna, M. H. Hayamizu, Donald Kendall, M. S. Klamkin, R. N. Ringenberg, M. S. R. K. Sastry, Perry Scheinok, D. V. Sitaramamurthy (India), R. Sivaramakrishnan & C. S. Venkataraman (India), Sidney Spital, J. L. Standig, Jimmy Vandergriff, Simon Vatriquant (Belgium), C. S. Venkataraman, M. D. Weick, Charles Wexler, J. W. Wilson, Dale Woods, K. L. Yocom, and Leonard Yonis.

A Trigonometric Identity Corrected

E 1840 [1965, 1129]. *Proposed by Simeon Reich, The Hebrew Reali Secondary School, Haifa, Israel*

Prove, for every odd integer x:

$$\sum_{k=1}^{(x-1)/2} \cos\frac{2k\pi}{x} \Big/ \sum_{k=0}^{(x-3)/2} \sin\left[\frac{\pi}{x}(2k+1)\right] = -\cot\frac{\pi}{2x}.$$

Solution by M. S. R. K. Sastry, University of Rochester. The formula as stated is wrong. The right member should be $-\tan(\pi/2x)$ as we will prove.

Multiplying the numerator and the denominator of the left member by $2\sin(\pi/x)$ and using elementary trigonometry, we can write the left member as

$$\frac{\displaystyle\sum_{k=1}^{(x-1)/2} \left\{\sin(2k+1)\frac{\pi}{x} - \sin(2k-1)\frac{\pi}{x}\right\}}{\displaystyle\sum_{k=0}^{(x-3)/2} \left\{\cos(2k)\frac{\pi}{x} - \cos(2k+2)\frac{\pi}{x}\right\}} = \frac{-\sin(\pi/x)}{1+\cos(\pi/x)} = -\tan\frac{\pi}{2x}.$$

Also solved by A. N. Aheart, P. N. Bajaj, C. A. Church, Jr., N. Ganesan (India), Sylvan Greene, H. R. Leifer, Beatriz Margolis, D. C. B. Marsh, Liselotte Miller, Perry Scheinok, D. V. Sitaramamurthy (India), Franklin C. Smith, Sidney Spital, J. L. Standig, C. S. Venkataraman & R. Sivaramakrishnan (India), Charles Wexler, Leonard Yonis, and David Zeitlin.

An Inequality of Absolute Values

E 1841 [1965, 1129]. *Proposed by D. S. Mitrinović, Belgrade University, Yugoslavia*

If a, b, c, d ($ad \neq bc$) are complex numbers and t is a real variable, prove the following inequalities:

$$\frac{|a\bar{b}-b\bar{a}|}{|ad-bc|+|a\bar{d}-b\bar{c}|} \leqq \left|\frac{at+b}{ct+d}\right| \leqq \frac{|ad-bc|+|a\bar{d}-b\bar{c}|}{|c\bar{d}-d\bar{c}|}.$$

An algebraic proof is preferred. What will happen when $c\bar{d}-d\bar{c}=0$?

Solution by C. Donald La Budde, New York University. From the conditions of the problem either $a\neq 0$ and $c\neq 0$, or $b\neq 0$ and $d\neq 0$. We assume, without loss of generality, that $ac\neq 0$, since we can always transform the inequality and consider the variable $u=1/t$. It suffices to prove the left hand inequality. We will prove

$$(1) \qquad |a\bar{b}-\bar{a}b|\,|ct+d| \leqq |at+b|\,(|ad-bc|+|a\bar{d}-b\bar{c}|).$$

Expanding the left member of (1) we have

$$\begin{aligned}
&|a\bar{b}-\bar{a}b|\,|ct+d| = |a\bar{b}ct-\bar{a}bct+a\bar{b}d-\bar{a}bd| \\
&= |a\bar{a}dt-\bar{a}bct+a\bar{b}d-b\bar{b}c-a\bar{a}dt+a\bar{b}ct-\bar{a}bd+b\bar{b}c| \\
&\leqq |a\bar{a}dt-\bar{a}bct+a\bar{b}d-b\bar{b}c| + |-a\bar{a}dt+a\bar{b}ct-\bar{a}bd+b\bar{b}c| \\
&= |\bar{a}t+\bar{b}|\,|ad-bc| + |at+b|\,|-\bar{a}d+\bar{b}c| \\
&= |at+b|\,(|ad-bc|+|a\bar{d}-b\bar{c}|).
\end{aligned}$$

Dividing (1) by the appropriate terms yields the desired inequality.

It is easily seen from differential calculus that the minimum value of $|ct+d|$ as a function of t is $|c\bar{d}-\bar{c}d|/2|c|$. Therefore, $|ct+d|$ can vanish for some real t if and only if $|c\bar{d}-\bar{c}d|=0$.

Also solved by M. S. Klamkin.

A Finite Summation

E 1842 [1965, 1129]. *Proposed by Stanton Philipp, Long Beach State College, California*

Evaluate

$$\sum_{r=0}^{n}\binom{n}{r}\sum_{k=0}^{r}(-1)^k\frac{r!}{k!}.$$

I. *Solution by K. L. Yocom, South Dakota State University.* The given sum can be written

$$\sum_{r=0}^{n}\frac{n!}{r!}\sum_{k=0}^{r}(-1)^k\binom{r}{k}.$$

The inner sum is zero for all r except $r=0$, and hence $n!$ is the value of the given sum.

II. *Solution by F. R. Olson, State University of New York at Buffalo.* Consider n objects, $a_1, \cdots, a_n$ arranged in n cells numbered 1 through n. In any permutation of these objects a certain number, say $n-r$, $0\leqq r\leqq n$, are in their proper

cells, that is, a_i in cell i, and the remaining objects are not. Of course, if $n-1$ objects are properly placed, then all n are. Thus all $n!$ permutations can be generated by selecting proper positions for $n-r$ objects (in $\binom{n}{n-r} = \binom{n}{r}$ ways) and deranging the remaining r objects in $\sum_{k=0}^{r} (-1)^k r!/k!$ ways for each value of r. (We note the last expression has value 0 for $r=1$.) Therefore $n!$ is the value of the given sum.

Also solved by A. D. Anderson, P. N. Bajaj, R. A. Bell, M. A. Bershad, M. T. L. Bizley (England), Shirley D. Braverman & Perry Scheinok, C. A. Church, Jr., D. D. Culbertson, R. V. Esperti, R. W. Feldman, H. W. Gatzke, Jr., Sylvan Greene, M. S. Greening (Australia), Emil Grosswald, P. G. Kirmser, M. S. Klamkin, C. D. La Budde, E. S. Langford, C. P. Lawes, D. C. B. Marsh, J. W. Moon, F. D. A Diophantine Problem

E 1843 [1965, 1130]. *Proposed by A. K. Austin, The University, Sheffield, England*

Given integers a and b, define the function $f(x) = ax^2 + bx$. Find all integers p, q, r such that $f(p) = f(q) + f(r)$.

Solution by G. J. Simmons, Sandia Corporation, Albuquerque, N. M.

We assume the nontrivial case: $a \neq 0$ and $(a, b) = 1$ (otherwise we suppress the common factor (a, b)). $f(p) = f(q) + f(r)$ can be written

$$(2ap + b)^2 + b^2 = (2aq + b)^2 + (2ar + b)^2. \tag{1}$$

This is in the form $u^2 + y^2 = v^2 + z^2$, treated in elementary texts on number theory (e.g. Dickson, *Introduction to the Theory of Numbers*, Dover, 1957, p. 43), where the general solution is shown to be of the form

$$u = \tfrac{1}{2}(m\mu + n\nu) = 2ap + b, \tag{2}$$

$$y = \tfrac{1}{2}(n\mu - m\nu) = b, \tag{3}$$

$$v = \tfrac{1}{2}\left| m\mu - n\nu \right| = 2aq + b, \tag{4}$$

$$z = \tfrac{1}{2}(n\mu + m\nu) = 2ar + b, \tag{5}$$

subject to certain restrictions on the parity of μ and ν.

Without loss of generality take $(m, n) = 1$ (otherwise, if $(m, n) = d$, the substitutions $m = dm'$, $n = dn'$, $\mu' = d\mu$, $\nu' = d\nu$ leave (2)–(5) unaltered with $(m', n') = 1$).

Suppose, for given a and b, there are integers p, q, r satisfying (1) with $m\mu > n\nu$. Elementary algebraic manipulations of (2)–(5) give

$$4ap = \mu(m - n) + \nu(m + n), \tag{6}$$

$$4aq = (\mu + \nu)(m - n), \tag{7}$$

$$4ar = \nu(2m), \qquad 4a(p - q) = \nu(2n). \tag{8}$$

Now (8) implies that $\nu = 2af$ for some integer f. Using this value of ν in (2) and

(3) we find that $m\mu$ and $n\mu$ are even, so μ is even; say $\mu=2w$. From (6) or (7), $a \mid w(m-n)$; but if c $(c>1)$ is any common divisor of a and w, (3) shows that $c \mid b$, contrary to $(a, b)=1$. Hence $a \mid (m-n)$. We put $m=ag+n$, where g is an integer. Further, $(m, n)=1$ implies that $(a, n)=1$, $(g, n)=1$. Finally, from (7), $\frac{1}{2}g(w+af)=q$, an integer.

We have shown that, if p, q, r satisfy (1), there are integers n, g, m, f, w such that, from (3), $nw-maf=b$, and

$$p = \tfrac{1}{2}g(w + af) + nf, \qquad q = \tfrac{1}{2}g(w + af), \qquad r = mf. \tag{9}$$

Conversely, for integers n, g with $(a, n)=1$, if we put $m=ag+n$, $(m, n)=1$, and let f and w be any solution pair of $nw-amf=b$ (of which there are infinitely many since $(n, ma)=1$), the numbers given by (9) will satisfy (1), as is seen by direct substitution. However, we must still restrict the choices so that $q=\frac{1}{2}g(w+af)$ is integral. For g even, all is clear.

g cannot be odd if a is even; because this requires that b and n be both odd; so $nw-afm=b$ implies w is odd, implies $w+af$ is odd, implies q is not integral.

Now if a and g are both odd and $m=ag+n$, then am, an are of opposite parity. Suppose one solution pair of $nw-amf=b$ is (w_0, f_0), then $n(w-w_0)=am(f-f_0)=amnt$ gives, for any t, another solution such that $w+af=(w_0+af_0)+a(m+n)t$. Since $a(m+n)$ is odd, $w+af$ will be even, and q integral, only for values of t having appropriate parity. So we have a process which produces all integral solutions (under the initial assumption that $m\mu>n\nu$).

If, on the other hand, $n\nu>m\mu$, entirely similar analysis gives

$$p = \tfrac{1}{2}g(w + af) - nw, \qquad q = \tfrac{1}{2}g(w + af), \qquad r = mf.$$

Also solved by Michael Goldberg, B. A. Hausmann, S. J., D. C. B. Marsh, Norman Miller, and Charles Wexler.

Editorial Note. Most of the solutions were incomplete, either because the derived formulas, although satisfying the given equation, did not provide for *all* integers which do so, or because they required knowledge of the factors of some integral expression which, if it is sufficiently large, may be impossible to find.

It is interesting to let $f(x)=ax^2+bx+c$. Clearly solutions of $f(p)=f(q)+f(r)$ are impossible if $a+b$ is even and c odd, or if c is not a multiple of (a,b). Hence, take $(a,b)=1$ without loss of generality, as above. We may then easily show that there are infinitely many integral solutions if $(a,b)=1$ and a, b, c are not all odd. In fact this is still true if we further require $p=q+1$. To find *all* integer solutions for *all* choices of a, b, c may be difficult.

Point with Irrational Distances from Three Given Points

E 1844 [1965, 1130]. *Proposed by A. K. Austin, The University, Sheffield, England*

Do there exist points A, B, C such that for all points D in the plane of A, B, C, the distances AD, BD, CD are not all rational.

I. *Solution by D. E. Crabtree and R. G. Bauer, University of Massachusetts.* The answer is affirmative. Let $A=(0, 0)$, $B=(\sqrt{2}, 0)$, $C=(\pi, 0)$. If the distances

AD, BD, CD to the point $D=(x, y)$ were all rational, then the numbers

$$\tfrac{1}{2}(AD^2 - BD^2 + 2) = \sqrt{2}\cdot x \quad \text{and} \quad AD^2 - CD^2 = 2\pi x - \pi^2$$

would both be rational. This leads to the conclusion that π is algebraic, a contradiction. (Moreover, AD, BD, CD cannot all be algebraic, as the above proof shows if we read "algebraic" for "rational" throughout.)

II. *Solution by Anders Bager, Hjorring Gymnasium, Denmark.* Yes, not only in the plane, but in a general Hilbert space. Let A and B be two fixed points, C their midpoint and P an arbitrary point. The parallelogram law tells us that

$$AB^2 = 2\cdot PA^2 + 2\cdot PB^2 - 4\cdot PC^2.$$

If we take $AB=2^{1/4}$, then PA, PB, PC cannot possibly all be rational.

Also solved by Walter Bluger, Ray Carry & J. W. Wilson, Red Cougar, Michael Goldberg, M. S. Klamkin, D. C. B. Marsh, Lieselotte Miller, P. R. Nolan (Ireland), and D. L. Silverman.

ADVANCED PROBLEMS

Solutions of Advanced Problems should be sent to J. Barlaz, Rutgers—The State University, New Brunswick, N. J. 08903. Solutions of Advanced Problems in this issue should be typed or written legibly on separate signed sheets and should be mailed before October 31, 1967. Contributors (in the United States) who desire acknowledgment of receipt of their solutions are asked to enclose self-addressed stamped postcards.

5480. *Proposed by Barbara L. Osofsky, Rutgers—The State University*

Let R be a ring with unity 1. Prove that a unital right R-module M is injective if and only if every R-homomorphism from a right ideal of R into M can be lifted to an R-homomorphism from R into M. If R is commutative, show that every indecomposable R-module is irreducible if and only if every indecomposable R-module is injective.

5481. *Proposed by C. C. Lindner, Coker College, Hartsville, S. C.*

Let G be a nonabelian group of squarefree order. Suppose that for any pair of subgroups H, K of G, $\{1\}\subsetneq H\subsetneq K$ implies that $N(H)\subseteq K$, where $N(H)$ denotes the normalizer of H in G. Prove that $|G|=p\cdot q$, where p and q are distinct primes.

5482. *Proposed by R. J. Weaver, University of Massachusetts*

Let I be a closed interval of real numbers. Let f and g be continuous mappings from $I^n=I\times I\times\cdots\times I$ into itself where f is surjective. Does there always exist a point P in I^n for which $f(P)=g(P)$?

5483. *Proposed by W. O. Egerland, Edgewood Arsenal, Md.*

Let $f(x)$ be continuous, $g(x)$ differentiable on I: $[a, b]$, $g(a)=0$, and $\lambda\neq 0$ a constant. If

$$|\, g(x)f(x) + \lambda g'(x)\,| \leqq |g(x)|$$

on I, then $g(x)\equiv 0$ on I.

5484. *Proposed by W. A. McWorter, University of British Columbia.*

Let p, q be distinct primes and consider the multiplication table of a semigroup S of $n=pq$ elements. If the element a of S occurs in those and only those positions on the off-diagonal (i.e., $s_i \cdot s_j = a$, s_i, $s_j \in S$, iff $j=n-i+1$), prove that S is the cyclic group of order n.

Show that the plane may be covered by squares of sides 1, 2, 3, $\cdots$ so that no two squares have an interior point in common. The side of each square must be a positive integer i, and for each i there is to be one and only one square.

5486. *Proposed by Ludwig Bruch.*

For any positive integer n, prove

$$\sum_{k=0}^{n-1} \csc^2 \left\{\frac{\pi}{2n}(2k+1)\right\} = n^2.$$

5487. *Proposed by Roy O. Davies, The University, Leicester, England*

Suppose that $f_0(x)$ is positive and Lebesgue integrable over (0, 1), that positive functions $f_1, f_2, \cdots$ are defined successively by the relations $f_{n+1}(x) = \{\int_0^x f_n(t)dt\}^{1/2}$ $(n = 0, 1, \cdots)$, and that $f_0(x) \geqq f_1(x)$ for $0 < x < 1$. Find $\lim_{n\to\infty} f_n(x)$.

(Based on an unpublished lemma of the late E. R. Reisenberg.)

5488. *Proposed by J. Z. Hearon, National Institutes of Health, Bethesda, Md.*

For any $n \times n$ matrix A, write $A = H + D$, where $D = \text{diag}(a_{11}, a_{22}, \cdots, a_{nn})$ and define $B = H - D$. Show that, if A is a continuant and λ is any root of A then $-\lambda$ is a root of B. Thus prove that an nth order continuant with zero diagonal and distinct roots is singular if n is odd.

5489. *Proposed by A. A. Mullin, University of California, Livermore*

Problem E 1735 [1965, 912] reestablished the result that every nontrivial weakly monotone multiplicative number-theoretic function f satisfies $f(n) = n^\alpha$ for some nonnegative real α. Prove the stronger result that every weakly monotone *generalized* multiplicative (see problem 5248 [1964, 1138]) number-theoretic function $f \not\equiv 0$ satisfies $f(n) = n^\alpha$ for some nonnegative real α.

SOLUTIONS OF ADVANCED PROBLEMS

Almost Disjoint Sets

5370 [1966, 311]. *Proposed by F. S. Cater, University of Oregon*

Let X be an infinite set with $\alpha = \text{card } X$ such that either $\alpha = \aleph_0$ or α has an

immediate predecessor. Prove that there exists a family M of subsets of X such that card $M>\alpha$ and

(1) card $(A_1\cap A_2)<\alpha$ for any two distinct members A_1, A_2 of M,

(2) for any subfamily N or M with card $N=\alpha$, there exists an $A\in M-N$ such that card $[(\cup_{B\in N} B)\cap A]=\alpha$. (Can the hypothesis on α be deleted?)

Solution by E. C. Milner, the University, Reading, England. It is well known (Tarski, Fund. Math., 12 (1928)) that there is a family M of subsets of X each of cardinal α such that card $M>\alpha$ and (1) holds. If, in addition, M is a maximal family of this kind, then (2) also holds. For suppose that N (well ordered) is the set $\{A_\nu: \nu<\omega(\alpha)\}$ and N is a subset of M of cardinal α ($\omega(\alpha)$ denotes the initial ordinal of cardinal α). For $\nu<\omega(\alpha)$ we can choose

$$x_\nu \in A_\nu - \bigcup_{\mu<\nu} A_\mu$$

since card $A_\nu=\alpha$ and card $[A_\nu\cap(\cup_{\mu<\nu} A_\mu)]<\alpha$. Put $C=\{x_\nu: \nu<\omega(\alpha)\}$. Since for $B\in N$, card$(B\cap C)<\alpha$, and M is maximal, it follows that there is $A\in M-N$ such that card$(A\cap C)=\alpha$ (A may be the set C). Therefore card $[(\cup_{B\in N} B)\cap A]=\alpha$.

The *cofinality cardinal* of $\alpha\geqq\aleph_0$, denoted by α', is the smallest cardinal β such that α is the sum of β cardinals each less than α. Clearly, $\alpha'<\alpha$. The above argument works if α is any *regular* cardinal (i.e., $\alpha'=\alpha$). (It is not known if there are regular cardinals other than $\aleph_0$ and the successor cardinals.) The proof above does not involve the generalized continuum hypothesis (or any weak form of this) $2^{\aleph_0}=\aleph_{\nu+1}$. Assuming the g.c.h. we can prove the following strengthening of the stated result which is also valid if α is *singular* (i.e., if $\alpha'<\alpha$).

THEOREM. *If card $X=\alpha\geqq\beta\geqq\aleph_0$, $\alpha'=\beta'$ and the g.c.h. holds, then there is a family M of subsets of X each of cardinal β such that card $M>\alpha$ and*

(1) *card$(A_1\cap A_2)<\beta$ if A_1, $A_2\in M$ and $A_1\neq A_2$,*

(2) *for any subfamily N of M with card $N=\alpha$, there is $A\in M-N$ such that $A\subset\cup_{B\in N} B$.*

A generalization of this theorem and certain related results will be included in a paper by P. Erdös, A. Hajnal and E. C. Milner.

Also solved by Paul Erdös, G. F. Schumm, and the proposer.

For the theorem of Tarski and related results on collections of almost disjoint sets, Schumm refers us to W. Sierpinski, *Cardinal and Ordinal Numbers*, Warsaw, 1958, 448–449. Erdös refers to his papers with L. Gillman and M. Henriksen, *An isomorphism theorem for real closed fields*, Annals of Math., 61 (1955), p. 542, ff. and with A. Hajnal and R. Rado, *Partition relations for cardinal numbers*, Acta Math. Hung. Acad. Sci., 19 (1964), p. 93, ff., for the theorems when α is singular.

Dimensionality of Compact Totally Disconnected Spaces

5378 [1966, 312]. *Proposed by S. W. Williams, Lehigh University*

Is every locally compact, totally disconnected space an 0-dimensional space? (Cf. W. J. Perwin, *Foundations of General Topology*, Academic Press, p. 98, #6.)

Solution by S. P. Franklin, Carnegie Institute of Technology. No. A sequence converging to two points is easily seen to be (locally) compact and totally disconnected but, being T_1 and not Hausdorff, cannot be zero dimensional.

For locally compact *Hausdorff* spaces the equivalence of the two concepts is easily proved using the corresponding fact for compact Hausdorff space.

We note that Pervin is not the only text book author to omit the Hausdorff hypothesis; see Hocking and Young, *Topology*, p. 147 Theorem 3-54.

Also solved by Roy Daigle, J. R. Isbell, James Joseph, M. D. Mavinkurve (India), P. S. Schnare, G. F. Schumm, Al Somayajulu, and the proposer.

For the situation in T_2 spaces, Schnare gives the reference, Hewitt and Ross, *Abstract Harmonic Analysis*, p. 12.

Entire Functions

5380 [1966, 420]. *Proposed by L. P. Comden and S. S. Mitra, Clarkson College of Technology, Potsdam, N. Y.*

Let $f(z)=u(x, y)+iv(x, y)$ be an entire function which is real for real values of z and strictly complex elsewhere, i.e., $v(x, y)\neq 0$ if $y\neq 0$. Prove that $f(z)=az+b$, where $a(\neq 0)$ and b are real. Cf. E 1696 [1965, 550].

I. *Solution by Robert Breusch, Amherst College.* Let $f(z)=\sum_{k=0}^{\infty} a_k z^k$, where the a_k are real. For $z=r\cdot e^{i\theta}$,

$$v(x, y) = \sum_{k=1}^{\infty} a_k r^k \sin k\theta.$$

Since $v(x, y)\neq 0$ for $y\neq 0$, $v(x, y)$ must have the same sign for all points with $y>0$; say $v(x, y)>0$ for $y>0$. (If $v<0$ for $y>0$, we work with $-f(z)$ instead of $f(z)$.) Since $n\cdot\sin\theta\pm\sin n\theta>0$ for every $n>1$, and every θ with $0<\theta<\pi$, we will have

$$\int_0^{\pi} (n\cdot\sin\theta \pm \sin n\theta)\cdot \sum_{k=1}^{\infty} a_k r^k \sin k\theta\cdot d\theta > 0.$$

The $\{\sin k\theta\}$ are orthogonal over $(0, \pi)$. Thus

$$n\cdot a_1 r(\pi/2) \pm a_n r^n(\pi/2) > 0,$$

$$|a_n| < n\cdot a_1 r^{n-1} \quad \text{for } n > 1, \text{ and all } r,$$

thus $a_n=0$ for $n>1$, $a_1>0$, and $f(z)=a_0+a_1 z$.

II. *Comment by R. P. Boas, Northwestern University.* The theorem is true in a somewhat more general form: we need only assume that $f(z)$ is real for real z and that v does not change sign for $y\neq 0$. In this form it was proved by Chebotaryoff (=Tschebotarëw), Math. Ann., 99 (1928), 660–686. A short and elementary proof is reproduced in Math. Reviews, 20, #5283.

Also solved by P. T. Bateman & N. T. Hamilton, Peter Bundschuh (Germany), C. K. Chui, G. Di Antonio, Irving Gerst, M. O. Gonzalez, M. G. Greening (Australia), D. A. Hejhal, M. S.

Klamkin, O. A. Nickel, J. J. Roseman, Al Somayajulu, L. J. Wallen, and the proposers.

Klamkin notes that the problem duplicates 4857 [1960, 597], where the solution using Picard's theorem applies, as in solution I above, if it is merely assumed that $v(x,y)$ does not change sign in the upper (lower) half plane.

Bateman and Hamilton in their solution avoid the Picard theorem through the use of an elementary lemma akin to the Weierstrass-Casorati theorem: If $f(z)$ is holomorphic for $R<|z|$, taking no values on some fixed segment $[\zeta_1,\zeta_2]$, then for some nonnegative integer n, $f(z)/z^n$ has a removable singularity at ∞.

Nonsolvable Groups

5381 [1966, 420]. *Proposed by V. H. Keiser, University of Colorado*

Let G be an imprimitive group in which all normal subgroups are transitive. Prove that G is nonsolvable.

Solution by Richard Stanley, Jet Propulsion Laboratory. More generally we prove that if G contains a minimal normal subgroup $A\neq 1$ which is transitive and abelian, then G is primitive. (This occurs as Exercise 8.8′ in H. Wielandt, *Finite Permutation Groups.*) Let G_1 be the subgroup of G fixing a letter and assume $G_1\subset H\subseteq G$ for a subgroup H. Since A is abelian and transitive, it is regular and $G=AG_1$. Choose $h\in H$ but $h\notin G_1$ where $h=ah_1$, $a\in A$, $h_1\in G_1$. Then $1\neq a\in H$. Since A is abelian and $G=AG_1$,

$$\{g_1^{-1}ag_1: g_1\in G_1\} = \{g^{-1}ag: g\in G\}\subseteq H.$$

But $\{g^{-1}ag: g\in G\}$ generates A as A is minimal normal. Hence $A\subset H$ and $H=G$. Thus G_1 is maximal and so G is primitive.

Also solved by M. G. Greening (Australia), and the proposer.

Small Submodules

5383 [1966, 420]. *Proposed by W. W. Leonard, Susquehanna University, Selinsgrove, Pa.*

A submodule E of a left A-module F is small in F if $E+H=F$ for any submodule H of F implies $H=F$. Prove that Z, the set of integers, is small in Q, the set of rational numbers. Is $Z^{(I)}$ small in $Q^{(I)}$, where I is an infinite set and $Z^{(I)}$ (resp. $Q^{(I)}$) is the direct sum of copies of Z (resp. Q)? All modules are considered as Z-modules.

Solution by Francis Sandomierski, University of Wisconsin.

THEOREM. (Notation of Problem 5383). *$Z^{(I)}$ is small in $Q^{(I)}$ if and only if I is finite.*

Proof. If I is finite and $Z^{(I)}+H=Q^{(I)}$, then by the second isomorphism theorem for groups $Q^{(I)}/H$ is isomorphic to $D=Z^{(I)}/Z^{(I)}\cap H$. Since $Q^{(I)}/H$ is divisible and $Z^{(I)}$ is finitely generated, it follows that D is a finitely generated divisible group, so $D=0$ and therefore $H=Q^{(I)}$, so $Z^{(I)}$ is small in $Q^{(I)}$.

If I is infinite, then Q is an epimorphic image of $Z^{(I)}$ by some homomorphism f. Since Q is divisible (Z-injective), f can be extended to $f^*: Q^{(I)}\to Q$. Since f is

onto, $Q^{(I)}=Z^{(I)}+\mathrm{Ker}(f^*)$; but since $f^*\neq 0$, $\mathrm{Ker}(f^*)\neq Q^{(I)}$. So $Z^{(I)}$ is not small in $Q^{(I)}$.

Also solved by G. A. Heuer, Ka Menehune, and the proposer.

Graphs of Finite Order

5384 [1966, 420]. *Proposed by D. E. Daykin, The University, Kuala Lumpur, Malaysia*

Let k be the independence number (coefficient of internal stability) of a graph G of finite order n with no circuits of uneven length. Prove that $\frac{1}{2}\leqq k/n\leqq 1$, and that these bounds are best possible. (See C. Berge, *The Theory of Graphs*, p. 48.)

Solution by H. V. Kronk, Harpur College. That $k\leqq n$ is obvious and the empty graph on n nodes has independence number n. Since G has no circuits (cycles) of uneven length, it is a bipartite graph and hence has chromatic number $\chi(G)\leqq 2$. For any ordinary graph G, it is well known that $k\cdot\chi(G)\geqq n$. Thus for a bipartite graph $2k\geqq n$. If n is even, then the complete bipartite graph $K_{n/2,n/2}$ has independence number $n/2$.

Also solved by J. F. Dillon, Myron Goldberg, A. M. Hobbs, William Lindgren, E. C. Milner (England), E. M. Palmer, and the proposer.

Associativity in Loops of Prime Order

5386 [1966, 421]. *Proposed by S. W. Williams, Lehigh University*

Let L be a loop of prime order, S be the set $\{x \mid (ax)b=a(xb);\ a,\ b\in L\}$, and R be the set $\{x \mid (ab)x=a(bx);\ a,\ b\in L\}$. Show that $S=R$.

Solution by M. G. Greening, University of New South Wales, Australia. For $x,\ y\in S$ we have $(a(xy))b=((ax)y)b=(ax)(yb)=a(x(yb))=a((xy)b)$, and $xy\in S$. Then, for $x,\ y,\ z\in S$, $(xy)z=y(yz)$ and S is an associative loop, as $e\in S$, and so a group. Then $x\in S$ implies $x^{-1}\in S$, so $xa\in S$ implies $a\in S$. Then the sets Sa, Sb, etc., are either identical or disjoint, as $xa=yb$ implies $b=y^{-1}(xa)=(y^{-1}x)a=za$ and $Sb=Sza=Sa$. Thus $o(S)\,|\,o(L)$ and $o(S)=1$ or p.

Similarly for $x,\ y\in R$, $(ab)(xy)=((ab)x)y=(a(bx))y=a(b(xy))$, and $xy\in R$, $e\in R$; R is a group with $o(R)=1$ or p. If $o(R)=p$, then $R=L$ and $R=S$ by the associativity of R; similarly $o(S)=p$ implies $S=L$ and $S=R$. Thus there are two cases: (1) $o(S)=p=o(R)$; $S=L=R$ and (2) $o(S)=1=o(R)$; $S=e=R$.

Also solved by the proposer.

An Equivalence Relation on a Finite Abelian Group

5387 [1966, 421]. *Proposed by Michael Gemignani, University of Notre Dame and Saint Mary's College*

Let G be a commutative group with identity 1. If g_1 and g_2 are in G, then define $g_1\sim g_2$ if $g_1g_2=g^2$ for some g in G. $\sim$ is an equivalence relation on G. If G

is a finite group of n elements, determine the number of distinct equivalence classes in $G/\sim$.

I. *Solution by C. C. Lindner, Coker College, Hartsville, S. C.* Let $G_2=\{x\in G: x^2=1\}$. Then the number of distinct equivalence classes in $G/\sim$ is $|G_2|$. For, if $G^2=\{x^2: x\in G\}$, then G^2 is a subgroup of G and is the equivalence class containing 1. It is easily seen that the other equivalence classes are just the right (left) cosets of G^2 in G. Hence the number of distinct equivalence classes in $G/\sim$ is $[G: G^2]$. But $[G: G^2]=|G_2|$; see, e.g., J. Rotman, *The Theory of Groups: an Introduction*, p. 29.

II. *Solution by Charles Wells, Western Reserve University.* Let $|G|=2^m r$, r odd. Then G is the direct product of a subgroup of order r and t cyclic subgroups, each of order a power of 2. This t is an invariant of G. Then $G/\sim$ contains 2^t equivalence classes: G has a basis $\{h_1, \cdots, h_n\}$ where the order of h_i is k_i (k_i a power of 2 for $i=1, \cdots, t$; k_i an odd prime power for $i=t+1, \cdots, n$). Every element of G is expressible uniquely as $\Pi_{i=1}^n h_i^{r_i}$, where r_i is determined (mod k_i). If $\Pi h_i^{r_i}=(\Pi h_i^{s_i})^2$, then $r_i=2s_i$ (mod k_i). If $1\leqq i\leqq t$, this means r_i is even. If $t+1\leqq i\leqq n$, any r_i has the form $2s_i$ (mod k_i). Thus $(\Pi h_i^{r_i})(\Pi h_i^{u_i})$ is a square if and only if r_i+u_i is even for every i, $1\leqq i\leqq t$, which happens if and only if $r_i\equiv u_i$ (mod 2) ($i=1, \cdots, t$). It follows that there are 2^t equivalence classes in $G/\sim$.

Also solved by Anders Bager (Denmark), L. Carlitz, J. P. Celenza, W. G. Dotson, Jr., N. Ganesan, J. D. Gillam, M. G. Greening (Australia), G. A. Heuer, Agatha Himmelfarb, E. C. Hook, R. B. Hora, Erwin Just, Roman Kaluzniacki, Tetsuzo Kimura (Japan), Betty Kvarda, Arthur Lieberman, N. R. Martin, J. J. Martinez, M. D. Mavinkurve (India), Ka Menehune, Wanda J. Mourant, N. S. Natarajan (India), Vishnu Parkash (India), F. D. Parker, R. F. Prisco, Donald Quiring, S. N. Rao (India), S. D. Rhodes, Azriel Rosenfeld, Al Somayajulu, Richard Stanley, Gomer Thomas, A. M. Vaidya (India), L. R. Vermani (India), and the proposer.

A Complex Rolle's Theorem

5389 [1966, 421]. *Proposed by D. J. Newman, Yeshiva University*

Let $f(z)$ be analytic and have $n+1$ zeros in a convex region C. Prove that $\operatorname{Re} f^{(n)}(z)$ vanishes somewhere in C.

I. *Solution by Robert Breusch, Amherst College.* For $n=0$, the statement is trivially true. Assume it has been proved for $n=m$, that is, for functions with $m+1$ zeros in C. Let f have $m+2$ zeros in C: $f(z)=(z-z_1)g(z)$, where g has $m+1$ zeros in C, and z_1 is in C.

$$f^{(m+1)}(z) = (z - z_1)g^{(m+1)}(z) + (m + 1)g^{(m)}(z).$$

By assumption, $\operatorname{Re}(g^{(m)}(z_2))=0$ for some z_2 in C. If $z_2=z_1$, then $\operatorname{Re}(f^{(m+1)}(z_1))=0$. If $z_2\neq z_1$, then with $\zeta=(z-z_1)/(z_2-z_1)$, $g^{(m)}(z)\equiv H(\zeta)$, $g^{(m+1)}(z)=H'(\zeta)/(z_2-z_1)$, $(z-z_1)g^{(m+1)}(z)=\zeta\cdot H'(\zeta)$, and thus $f^{(m+1)}(z)\equiv F(\zeta)=\zeta\cdot H'(\zeta)+(m+1)H(\zeta)$, with $\operatorname{Re}(H(1))=0$.

Write $H(\zeta)=u(\xi,\eta)+iv(\xi,\eta)$, $H'=u_1+iv_1$, and it follows that $\operatorname{Re}(f^{(m+1)}(z))=\operatorname{Re}(F(\zeta))=\xi\cdot u_1-\eta\cdot v_1+(m+1)u$. Since $\xi^{m+1}\cdot u(\xi, 0)$ vanishes at $\xi=0$ and at

$\xi=1$, we have by Rolle's Theorem, $\xi_0^m[\xi_0 \cdot u_1(\xi_0, 0)+(m+1)\cdot u(\xi_0, 0)]=0$ for some ξ_0, $0<\xi_0<1$, whence Re $(F(\zeta))=0$ for some point $\zeta=(\xi_0, 0)$ on the line segment from 0 to 1. We have shown that Re $(f^{(m+1)}(z))=0$ for some z on the line segment between z_1 and z_2, and since C is convex, this completes the proof.

II. *Partial Solution by M. D. Mavinkurve, Bombay, India.* To prove the case $n=1$, let z_1 and z_2 be the two zeros. If $z_1=z_2$, then $f'(z_1)=0$. If $z_1\neq z_2$, consider the real function $\phi(z)=u \cos \beta - v \sin \beta$, β fixed, $u+iv=f(z)$. $\phi(z_1)=\phi(z_2)=0$. Applying Rolle's Theorem on the segment $\overline{z_1z_2}$ we have $\partial\phi/\partial s=0$ somewhere in the interior of the segment, i.e.,

$$\cos\beta\cdot\frac{\partial u}{\partial s}-\sin\beta\cdot\frac{\partial v}{\partial s}=\cos\beta\cdot\frac{\partial u}{\partial s}+\sin\beta\cdot\frac{\partial u}{\partial n}=0.$$

This means that the derivative of u in a direction making angle β with $\overline{z_1z_2}$ is zero. Since β is arbitrary, it follows that the directional derivative of u in any direction vanishes somewhere on $\overline{z_1z_2}$. In particular, $\partial u/\partial x=\text{Re } f'(z)=0$.

III. *Solution by the proposer.* We assume that $z_1, \cdots, z_{n+1}$ are distinct zeros of $f(z)$. (Simple modifications are possible to accommodate multiple zeros.) We prove

$$0=\int\cdots\int_{\substack{x_1,x_2,\cdots,x_n\geqq 0\\ x_1+x_2+\cdots+x_n\leqq 1}} f^{(n)}(x_1z_1+\cdots+x_nz_n+x_{n+1}z_{n+1})dx_1\cdots dx_n,$$

(where x_{n+1} is an abbreviation for $1-x_1-x_2-\cdots-x_n$), whence the required result follows immediately.

We proceed by induction, noting the validity of the result for $n=0$. Assume it holds for $n-1$; then

$$\int\cdots\int_{\substack{x_1,\cdots,x_n\geqq 0\\ x_1+\cdots+x_n\leqq 1}} f^{(n)}(x_1z_1+\cdots+x_{n+1}z_{n+1})dx_1\cdots dx_n$$

$$=\frac{1}{z_n-z_{n+1}}\int\cdots\int_{\substack{x_1,\cdots,x_{n-1}\geqq 0\\ x_1+\cdots+x_{n-1}\leqq 1}} f^{(n-1)}(x_1z_1+\cdots+x_{n-1}z_{n-1}$$

$$+(1-x_1-\cdots-x_{n-1})z_n)dx_1\cdots dx_{n-1}$$

$$-\frac{1}{z_n-z_{n+1}}\int\cdots\int_{\substack{x_1,\cdots,x_{n-1}\geqq 0\\ x_1+\cdots+x_{n-1}\leqq 1}} f^{(n-1)}(x_1z_1+\cdots+x_{n-1}z_{n-1}$$

$$+(1-x_1-\cdots-x_{n-1})z_{n+1})dx_1\cdots dx_{n-1},$$

and this last is 0 by the inductive hypothesis.

Analysis.

Lectures on Functional Equations and their Applications. By J. Aczel. Translated by Scripta Technica, Inc. Supplemented by the Author. Edited by Hansjorg Oser. Academic Press, New York, 1966. xix+510 pp. $19.50. A systematic treatise based on, but much enlarged from the German edition of 1961. Bibliography of 114 pages. P, L.

Functional Analysis. By George Bachman and Lawrence Narici. Academic Press, New York, 1966. xiv+530 pp. $14.50. " . . . either a one-or-two-semester course . . . The book meets the demand for an in-depth, axiomatic, and highly detailed treatment of functional analysis in its pure aspects." Assumes only advanced calculus and linear algebra. T (16–17).

Eight Papers on Differential Equations and Functional Analysis. By F. A. Berezin, V. I. Judovič, M. A. Krasnosel'skii, O. A. Ladyženskaja, V. P. Palamodov, V. A. Solonnikov, M. G. Šur, N. N. Ural'ceva, B. R. Vainberg, P. P. Zabreiko. Amer. Math. Soc. Translations, Series 2, Vol. 56. American Mathematical Society, Providence, R. I., 1966. iv+295 pp. $15.00. P, L.

Elementary Partial Differential Equations. By Paul W. Berg and James L. McGregor. Holden Day, San Francisco, 1966. ix+421 pp. $11.75. Linear equations with constant coefficients in two independent variables, heat equations, eigenfunction expansions, inhomogeneous problems, Fourier series, existence, uniqueness, representation of solutions, wave equation, infinite and semi-infinite intervals, initial boundary value problems, Laplace equation. Based on lectures given to "majors in mathematics, the physical sciences, and engineering, at different stages in their education . . . to provide . . . techniques . . . and to prepare . . . for further study in partial differential equations and linear analysis by furnishing a basis for intuition in these subjects, namely, a thorough familiarity with their simplest typical problems." T (15–17).

Calculus of Variations and Partial Differential Equations of the First Order. By C. Caratheodory. Part I. Translated by R. B. Dean and J. J. Brandstatter. Holden-Day, San Francisco, 1965. xvi+171 pp. $8.50.

Square Summable Power Series. By Louis de Branges and James Rovnyak. Holt, Rinehart and Winston, New York 1966. vii+104 pp. $4.50. " . . . an introduction to Hilbert space and analytic function theory, . . . centered around the invariant subspace concept. Its principal feature is the extensive use of formal power series methods to obtain and sometimes reformulate, results of analytic function theory . . . developed from lecture notes of courses taught at Lafayette College (Spring 1959), Bryn Mawr College (1960–61), and Purdue University (1963–64) . . . " T (15–16), S, P.

JWKB Approximation, Contributions to the Theory. By N. Froman and P. O. Froman. North-Holland, Amsterdam, 1965. 138 pp. $4.50. This book presents a new treatment of the J.W.K.B. (after Jeffreys, Wentzel, Kramers and Brillouin) approximation. The method is applied to the detailed examination of some problems in quantum mechanics, but is also suitable for other applications. P.

Approximation of Functions. Edited by Henry L. Garabedian. American Elsevier, New York, 1965. vii+220 pp. $13.00. Proceedings of a Symposium at General Motors Research Laboratories, Warren, Michigan, 1964. This volume contains thirteen papers in the categories of fundamental problems, rational approximations, linear methods, nonlinear methods, and applications. P.

Introduction to Real Analysis. By Casper Goffman. Harper and Row, New York, 1966. xi+160 pp. $7.50. Real numbers, topology of reals, infinite series, continuous functions, special functions, sequences and series of functions, differential, integration (to Riemann-Stieltjes), power series, Fourier series. T (15–16). Reviewed by L. W. Cohen in *Science*, 17 Febr. 1967.

Variational Methods for Eigenvalue Problems. An Introduction to the Weinstein Method of Intermediate Problems. By S. H. Gould. Univ. of Toronto Press, Toronto, 1966. xvi+275 pp. $8.50. An updating of the original edition. S, P.

Lectures on Riemann Surfaces. By R. C. Gunning. Preliminary Informal Notes of University Courses and Seminars in Mathematics. Princeton Univ. Press, N.J., 1966. iv+254 pp. $3.75. " . . . notes for . . . lectures given at Princeton . . . 1965–66. The subject . . . was compact Riemann surfaces, considered as complex analytic manifolds . . . The aim of the lectures, in addition to treating a beautiful subject for its own sake, was to introduce the student to some techniques (recently developed for dealing with complex analytic functions in several dimensions) in the case of one complex variable, where things are simpler and the results more complete. S, P.

Differential Equations, Stability, Oscillations, Time Lags. By A. Halanay. Academic Press, New York, 1966. xii+528 pp. $19.50. Differential and differential-difference equations, stability of nonlinear control systems, theory of oscillations, systems with time lag. P.

Calculus of Variations and Optimal Control Theory. By Magnus R. Hestenes. Wiley, New York, 1966. xii+405 pp. $12.95. " . . . presents the basic mathematical theory for problems in the calculus of variations and optimal control theory at a fairly advanced level . . . maximum and minimum for functions of N variables, with or without inequality constraints . . . the classical fixed end point problem . . . optimal control problems, including the theory for the classical problems of Mayer and Bolza . . . interrelations between the calculus of variations, dynamic programming, and the works of Pontryagin and his school . . . an indirect sufficiency proof is given . . . " T (17–18), S, P.

Studies in Real and Complex Analysis. Edited by I. I. Hirschman, Jr. MAA Studies in Mathematics, Vol. 3. Prentice-Hall, Englewood Cliffs, N.J., 213 pp. $4.00. A worthy third volume in the well-known Studies in Mathematics Series. Contents: Several Complex Variables; Nonlinear Mappings Between Banach Spaces; What is a Semi-Group?; The Laplace Transform, the Stieltjes Transform and their Generalizations; A Brief Introduction to the Lebesgue-Stieltjes Integral; Harmonic Analysis; Toeplitz Matrices. S (16–17), P, L.

Topological Vector Spaces and Distributions. Vol. I. By John Horvath. Addison-Wesley, Reading, Mass., 1966. xii+449 pp. $12.75. " . . . an elementary introduction to topological vector spaces and their most important applications: the theory of distributions of Laurent Schwartz . . . grew out of courses taught at the Univ. of Maryland, the Université de Nancy, and the Universidad de Los Andes, Bogota . . . In preference to other convergence theories I used exclusively filters. . . . The theory of distributions is presented, as originally by Schwartz, as a theory of duality of topological vector spaces . . . Volume II, which I hope will appear someday, should start with an exposition of the theory of integration and introduce some important Banach spaces of distributions . . . " T (16–17), S (partial differential equations), P, L.

Introduction to Analytic Functions. By Wilfred Kaplan. Addison-Wesley, Reading, Mass., 1966. ix+212 pp. $7.95. " . . . an elementary introduction . . . for students of science and engineering . . . based directly on Chapter nine of the author's Advanced Calculus, and also includes a completely new chapter on analytic functions of several complex variables . . . " T (16–17).

Discourse on Fourier Series. By Cornelius Lanczos. Hafner, New York, 1966. viii+255 pp. $9.85. Developed from lectures to a mixed audience at the University of Washington in 1947. " . . . the primary aim . . . was to convey something of the excitement and enthusiasm which imbued the hundreds of mathematicians who have contributed to this remarkable chapter . . . " S (16–17), P.

Introduction to Diophantine Approximations. By Serge Lang. Addison-Wesley, Reading, Mass., 1966. vii+83 pp. $6.75. " . . . The quantitative aspects of the theory of diophantine approximations are, at the moment, still not very far from where Euler and Lagrange left them. Very recent work seems to have opened some fruitful lines of research, and in this book we shall illustrate by significant special examples three aspects from the theory of diophantine approximations. It is unusual to find a mathematical theory which is in a state as primitive and naive as the present one, and there is of course some delight in catching it in that state. In fact, this book may be used for a course in number theory, addressed to undergraduates, who will thus be put in

contact with interesting but accessible problems on the ground floor of mathematics." Bibliography. S (16–17), P.

Introduction to Transcendental Numbers. By Serge Lang. Addison-Wesley, Reading, Mass., 1966. vi+105 pp. $7.50. " . . . The theory of transcendental numbers is reaching a stage where it is ready to take its place as one of the most attractive branches of mathematics. It consists in determining the transcendence and algebraic independence of numbers obtained as values of classical functions, suitable normalized . . . The theory has applications ranging from a very elementary setting (concerning the function e^t), to rather sophisticated contexts, having to do with abelian functions and automorphic functions. The embedding of 'elementary' results in broad coherent theories has been known to cause acute cases of paranoia to persons who prefer 'simple' significant examples to the elaboration of the more extensive theories. I personally like both, but I have made an attempt to keep the more elementary portions separate from the others, and hence more accessible for the reader of limited mathematical background, . . . Historical notes at the end of each chapter serve as much to describe past work in the subject as to suggest further possibilities and conjectures. . . . it is remarkable that a mathematical theory as old as the theory of transcendental numbers (dating back to Hermite's first result of 1873, the transcendence of e) is still in what can only be called an underdeveloped state . . . " Bibliography. S (16–17), P.

Approximation of Functions. By G. G. Lorentz. Holt, Rinehart and Winston, New York, 1966. ix+188 pp. $5.00. "My purpose has been to write an easily accessible book on the approximation of functions that is simple and without unnecessary details, and is also complete enough to include the main results of the theory, including some recent ones. . . . The leitmotiv of the book is that of the degree of approximation. . . . " T (16–17), S, P.

Hill's Equation. By Wilhelm Magnus and Stanley Winkler. Interscience, New York, 1966. viii+127 pp. $8.50. An "orientation to homogeneous, linear, second order differential equations with real, periodic coefficients, which can all be reduced to the equation associated with G. W. Hill's famous memoir of 1877 on the lunar perigee." Bibliography. P, L.

Entire Functions. By A. I. Markushevich. Translated by Scripta Technica, Inc., Translation Editor Leon Ehrenpreis. American Elsevier, New York, 1966. iv+105 pp. $6.50. A brief exposition on functions equal to sums of everywhere convergent power series to assist the student who has had elementary calculus and knows the simplest facts about complex numbers "to understand better and more thoroughly the facts related to an academic course." S (15–16), P.

Calculus of Residues. By D. S. Mitrinovic. Noordhoff, Groningen, 1966. 87 pp. $1.90 (paper). Problems with solutions, classified as introductory, direct application of the residue theorem, integration along the real axis, rational functions of $\cos\theta$ and $\sin\theta$, summation of series. S, P.

Lectures on Choquet's Theorem. By Robert R. Phelps. Van Nostrand, Princeton, N.J., 1966. v+130 pp. $2.50 (paper). " . . . an important recent chapter in functional analysis . . . has applications to analysis, probability, potential theory, and functional analysis . . . presupposes a knowledge of integration theory and elementary functional analysis, including the Krein-Milman theorem and the Riesz representation theorem." In the Van Nostrand Mathematical Studies series of "lecture notes, trial manuscripts, and other informal mathematical studies . . . focusing on the living and growing aspects of mathematics." Reviewed by L. D. Young in *Science*, 2 Dec. 1966. P.

Integral Equations and their Applications Vol. I. By W. Pogorzelski. Pergamon Press, New York and Polish Scientific Publishers, Warsaw, 1966. xi+714 pp. $18.50. General properties of Fredholm and Volterra equations, systems of integral equations (linear and nonlinear), applications to differential equations, Cauchy type integrals, boundary problems, singular integral equations. In spite of the untimely death of the author, Volume II is completed and will deal with polyharmonic equations, generalized analytic functions, multidimensional singular integral equations, applications to partial differential equations and to physics and technology applications. P, L.

Linear Spaces of Analytic Functions. By Pasquale Porcelli. Rand McNally, Chicago, 1966. ix+158 pp. $8.00. " . . . about one-third of the material the author presents is a first-year graduate course in complex variables . . . has for its central theme approximation theory." Log mean, functions with positive real part, boundary values and H_P spaces, H_P algebras, ring of analytic functions, approximation, topology of pointwise convergence, the Fourier transform, infinite systems of equations in Hilbert space, moment problem. S, P.

Integral, Measure and Derivative: a Unified Approach. By G. E. Shilov and B. L.Gurevich. Translated from the Russian by Richard A. Silverman. Prentice-Hall, Englewood Cliffs, N.J., 1966. xiv+233 pp. $8.95. Uses the Daniell scheme "which starts from the concept of an elementary integral defined (axiomatically) on a family of elementary functions" rather than the more usual Lebesgue-Radon-Frechet approach. "In preparing the American edition, we gave the book a complete overhaul." T (16–17), S, P, L.

Laplace Transform Theory. By M. G. Smith. Van Nostrand, Princeton, N. J., 1966. x+123 pp. $6.00. " . . . short rigorous account of the elementary theory . . . some of its more useful applications . . . primarily for mathematics students . . . " T (16–17), S, P.

Methods of the Theory of Functions of Several Complex Variables. By V. S. Vladimirov. Translated by Leon Ehrenpreis. M.I.T. Cambridge, Mass. 1966. xi+353 pp. $12.00. " . . . a systematic exposition of . . . single sheeted (schlicht) domains of homorphy and its applications to quantum field theory, to the theory of functions, and to differential equations with constant coefficients. In recent years, the theory of functions of several complex variables, which previously had not found much application in natural science, unexpectedly found numerous and fruitful applications in quantum field theory . . . The successes achieved in quantum field theory by this route have in turn had influence on the theory of functions of several complex variables . . . the theory of generalized functions is used extensively in the monograph . . . " S, P.

Algebraic Topology. By Edwin H. Spanier. McGraw-Hill, New York, 1966. xiv+528 pp. $15.00.

The dust jacket blurb begins "This long-awaited text, suitable for graduate courses, is a comprehensive survey of the fundamental ideas of algebraic topology" and this is a very good one-sentence description of the book. The first four chapters—fundamental group, covering spaces, polyhedra, and homology—would form a good one semester basic graduate course, while the last five chapters give a very good background for much of the present research in algebraic topology and its applications to differential topology and manifold theory. This is not to say that this is an easy book to read by oneself. The material is clearly, but concisely, presented. In some sections there is more generality than some readers would prefer. However, the fine introductions to each chapter and to each

section, the well-chosen exercises which lead to extensions of the theory, the excellent choice of material, the absence of confusing notation, and the absence of very technical propositions make this by far the best text on the subject at present and probably for some time to come.

FRANKLIN P. PETERSON, M.I.T.

An Introduction to Probability Theory and Its Applications. Vol. II. By William Feller. Wiley, New York, London, 1966. xviii+626 pp. $12.00.

The first volume of the work under review was published in 1950, and a second edition appeared in 1957. In volume I, Professor Feller presented a rigorous introduction to discrete probability theory (as well as to certain types of random or stochastic processes) which was warmly received by a large general readership whose mathematical background was not too extensive, as well as by serious students of probability. Volume II is devoted, in the main, to continuous sample spaces; and the reader is required to have a knowledge and appreciation of the results and techniques of analysis (hard and soft).

This volume contains nineteen chapters, the first three of which supplement material contained in volume I. The last sixteen chapters are devoted to a very elegant presentation of material that is often presented in graduate courses and seminars under the general title "advanced probability theory." The text contains a large number of examples and problems which indicate the applications of probabilistic reasoning and methodology in various branches of analysis. The reader will also find a discussion of many topics of historical and methodological interest. The author's beautiful expository style, which made volume I such a pleasure to read and study, has remained invariant.

This book is recommended as a text or supplementary text for courses in advanced probability, and as a rich source of material for seminars devoted to topics in probability and stochastic processes. Volumes I and II of Professor Feller's book constitute a unique contribution to the literature of probability theory.

A. T. BHARUCHA-REID, Wayne State University
and Mathematics Research Center,
The University of Wisconsin

An Introduction to Computer Programming. By Henry Mullish. Gordon and Breach, New York, 1966. xi+244 pp. $5.00 (paper) $14.50 (cloth).

The preface of this book makes the statement "Whereas we do not claim that after having assimilated the contents of our text the reader will have become a professional programmer, nevertheless, we feel that a thorough understanding of our material will help create a substantial understanding of the techniques employed in solving many of today's common tasks in addition to alerting him to methods of solving other problems in areas not covered by this text."

The style of the statement is a fair indication of the style of the book. Though it could serve as a programming primer for a student with a knowledge of high school mathematics, there are serious faults even at this level. For example, there are no answers to the quizzes—an especially exasperating omission since 11 of the book's 244 pages are completely blank! Flow charts are introduced with no explanation whatsoever; the flow chart on page 133 appears with a remote connector and the standard box shape convention (almost), neither of which the author bothers to explain. The chapter on matrix algebra begins with "A matrix is no more than several columns of numbers."

The needs of readers of this MONTHLY will be better served by other texts on this subject, e.g., McCracken's "A Guide to FORTRAN Programming" or by any of the IBM student texts on FORTRAN, at a fraction of the almost unbelievable price of this book.

EDWARD SELIGMAN, United Aircraft Research Laboratories

Group Theory. By Eugene Schenkman. Van Nostrand, Princeton, N.J., 1965. 289 pp. $9.50.

Perhaps this book's most striking characteristic is its unusually lucid architecture. Of its three sections, the first is devoted to the elementary parts of the theory. The second, which is the nucleus of the book, deals with Sylow theory, free groups, free products, nilpotent groups, and solvable groups. The chapter on free groups has a particularly elegant presentation of the Subgroup Theorem. The last section of the book contains a short introduction to the theory of representations of finite groups, which goes just far enough to prove Burnside's Theorem and some interesting modern results such as Thompson's Theorem on normal p-complements. The bibliography is short and not very useful. On the whole this book is an excellent introduction to group theory, wide in scope and elegant and clear in style.

OLIVER PRETZEL, Free University, West Berlin

Differential Equations of Applied Mathematics. By G. F. D. Duff and D. Naylor. Wiley, New York, 1966. xi+423 pp. $11.95.

The book represents a course on the Laplace, heat and wave equations by the authors to senior undergraduates in applied mathematics and engineering science. Modern techniques are used, and the theories of distributions and Fourier transforms are stressed. The physical backgrounds of many of the problems are treated in detail. The material is explained well, and exercises are numerous.

MARTIN SCHECHTER, Belfer Graduate School of Science, Yeshiva University

Topology from the Differentiable Viewpoint. By John W. Milnor. Univ. Press of Virginia, Charlottesville, 1965. ix+64 p. $3.00.

In this short volume several of the most important results and techniques of algebraic and differential topology are introduced through an exposition in the spirit of "advanced mathematics from an elementary point of view." The reader is assumed to be familiar with very elementary point set topology and a few of the basic theorems of real variable theory.

The Sard-Brown Theorem is proved and the degree of a map is defined using the concept of a regular value of a smooth mapping. Hopf's Theorem is proved by showing that two maps of an n-sphere into itself are homotopic if and only if they have the same degree. The notation of cobordism is introduced and the relation between framed cobordism classes of manifolds and homotopy classes of maps of a sphere into a sphere is established.

E. H. BROWN, JR., Brandeis University

Elementary Matrices (Tutorial Text No. 3). By D. S. Mitrinović. Noordhoff, Groningen, 1965. 75 pp. $2.75.

This pleasant little book makes available to English language readers a concise resumé of elementary matrix theory together with an interesting collection of problems which had previously appeared only in Serbo-Croatian. The basic definitions and elementary theorems concerning matrices and determinants are clearly stated, but no proofs are given. Topics covered include products and powers of matrices, determinants, inverses, special matrices, rank, linear forms and equations, eigenvalues and eigenvectors, and elementary canonical forms. The 151 problems vary widely in difficulty and hints are freely given. The book should prove attractive to students wishing to instruct themselves, and it will also serve well as a supplement to regular course work.

G. N. RANEY, University of Connecticut

How to Gamble if You Must: Inequalities for Stochastic Processes. By L. E. Dubins and L. J. Savage. McGraw-Hill, New York, 1965. xiv+250 pp. $12.75.

"A gamble is, of course, a probability measure γ on subsets of fortunes. In the tradition of recent decades, such a measure would be defined only on a sigma-field of subsets of F and required to be countably additive on that sigma-field. If this tradition were followed in this book, tedious technical measurability difficulties would beset the theory from the outset." With this single remark the authors lay bare the rationale behind the book and open a whole new field of endeavor. From an interest in how they would play "red and black" has come a book on stochastic processes with probability measures which may be only finitely additive.

That such is no restriction is shown by the fact that the authors develop a considerable theory of such processes in their own right, with happy analogies to some of the more usual situations. They consider countably additive measures as particularly important special cases and, where possible, indicate similarities and differences between the two kinds of additivity. Perhaps it takes authors of this stature to break new ground in this fashion. One may foresee not only a series of papers and theses resulting from this work alone but also from similar lessening of restrictions in other fields.

Unfortunately it may take several such papers before we all understand this material. Clearly the authors have had a good time thinking and writing about gambles, but they have not done nearly enough to let us in on what they are up to. They say, "The number of technical terms and notations introduced is large in spite of economy drives, but only a few are in use in any one section and many are short-lived." (With regard to the latter: Why, then, introduce them?) A rough count produced 40 definitions and 30 theorems in the first substantive chapter, and only 4 examples. While some of the terms are surely meant to be helpful ("thrifty strategies," "miserly functions," "rich man's casino"), others sound like in-jokes: "full house" (not what you think), "income-tax casinos" and their sub-houses "primitive casinos," "houses of inequity," and the ultimate horror "casinoe" ("rhymes with 'canoe' ").

For the mathematical reader approaching this *de nouveau* (And that includes most of us; non-mathematical readers stay clear!), the best approach is through specific examples. The following list of chapter headings is arranged to indicate a possible line of immersion with minimum trauma. Chapter 5, Red-and-Black, is a binomial game. (One unhappy misprint here: In Figure 1, the abscissa measures f, not w.) Chapter 6, Primitive Casinos, is a slight generalization in which the amount to be won is some non-unit multiple of the stake. Chapter 4, Casinos with Fixed Goals, could be studied separately for its interesting inequalities. Chapter 3, Strategies, can best be digested by "flashbacks" while reading 4, 5, and 6. Chapter 8, Houses on the Real Line, deals with some specific cases and concludes with the only example likely to be of interest to non-mathematical gamblers. Chapter 9, Three Particular Kinds of Casinos, is just that. Now, since they can be postponed no longer, Chapter 2, The Abstract Problem, and Chapter 7, General Principles, might be taken together, realizing that again many flashbacks for notation have previously occurred. Chapter 10, One Lottery Strategies, on sums of independent and identically distributed random variables, will fix the general ideas nicely, as will Chapter 11, Fair Casinos. Chapter 12, The Scope of Gambler's Problems, looks at more general stochastic process problems from a gambling (finitely additive measure) point of view. Several master's theses will eventually emerge from this chapter.

The book will repay (and require) serious study at the graduate level. It is unfortunate that a major share of the impact of its ideas will have to wait for a further, more extensive, exposition.

ROBERT KOZELKA, Williams College

Topology and Order. By Leopoldo Nachbin. Van Nostrand, Princeton, N. J. 1965. vi+122 pp. $2.50.

In this paperback the author first presents the basic concepts of topological spaces and ordered sets, and then proceeds to study systematically the interdependence of these notions. Thus emerge topological ordered spaces, in particular normally ordered spaces, compact ordered spaces, and completely regular ordered spaces. Furthermore, uniform ordered spaces and locally convex ordered vector spaces are treated. Much of the material stems from the research of the author.

The book is eminently readable and should be accessible to anyone with a rudimentary knowledge of general topology. (The book is actually self-contained relative to topological notions, but some of these are presented, practically speaking, only in outline form.) Theorems are carefully stated and the proofs are easy to follow. At times the reading elicits some excitement; this occurs when the interplay of order and topology reveals some unexpected results.

A. E. DANESE, SUNY at Buffalo

Applied Complex Variables. By John Dettman. Macmillan, New York, 1965. ix+481 pp. $9.95.

This is an extremely well written book dealing with the foundations and applications of analytic function theory. It is intended primarily for undergraduate engineers and physicists who have completed a modern calculus course; but, due to its scope and contents, it could be used equally well as an introduction to complex variables for mathematics majors.

The book is divided into two parts. Part I (Chapters 1–5) is devoted to the fundamentals of analytic functions and covers the main ideas of complex integration, complex sequences and series, and residue calculus. Part II (Chapters 6–10) is a collection of applications of the ideas developed in the first part. The chapter headings of this part are Potential Theory, Ordinary Differential Equations, Fourier Transforms, Laplace Transforms and Asymptotic Expansions. Each of these subjects is treated independently, depending only on Part I. This format, as the author states, makes this book readily adaptable to either a two semester course or a one semester course consisting of Part I and any one (or more) of the five applications.

The book is well documented with illustrative examples and the discussion of each topic is complemented with a set of integrated exercises. The proofs are clear and usually well motivated. Typographical errors are scarce.

RODNEY ANGOTTI, SUNY at Buffalo

Vector Spaces of Finite Dimension. By G. C. Shephard. Oliver and Boyd, London, 1966. viii+200 pp. $3.25.

This book covers the topics which the title suggests, including multilinear algebra and unitary spaces. There are several features which distinguish this book from most others in this area. Matrices are scrupulously avoided until the final chapter, where matrix interpretations of the results obtained earlier are given. The style is concise, with a lack of heuristic discussion for motivation. The geometric interpretations are almost completely ignored. (There is only one illustration in the entire book!) In short, this is not a self-teaching book; the instructor's role in supplying motivation, specific examples, etc., would be crucial.

The book is clearly written, and would be useful as a reference or as a guide for review of the subject.

H. E. CHRESTENSEN, Reed College

Partial Differential Equations. By Lipman Bers, Fritz John, and Martin Schechter. Wiley, New York, 1964. xiii+343 pp. $10.70.

In June and July of 1957 lectures on the theory of partial differential equations were delivered at the Seminar on Applied Mathematics sponsored by the American Mathematical Society at the University of Colorado. The book is an expanded and edited version of those lectures. The preface states, "This is neither a textbook for beginners, since standard material is omitted, nor a reference book for specialists. It is aimed, as the oral presentation was, at mathematicians not necessarily familiar with the field of partial differential equations who want to acquire an understanding of some of the problems and methods in this discipline. The technical prerequisites are very modest. A student familiar with the fundamentals of real and complex function theory and with the elements of functional analysis should have no difficulty in following the presentation."

The book is at the highest level of exposition. The stated goal of the preface is authoritatively and admirably fulfilled. Despite the delay between the lectures and their publication, the book should serve as an inspiration and model for future expository writing.

A. M. WHITE, Harvey Mudd College

NEWS AND NOTICES

EDITED BY RAOUL HAILPERN, SUNY at Buffalo

Readers are invited to contribute to the general interest of this department by sending news items to Raoul Hailpern, Mathematical Association of America, SUNY at Buffalo (University of Buffalo), Buffalo, New York 14214. Items must be submitted at least two months before publication can take place.

PERSONAL ITEMS

Professor Foster Brooks, Kent State University, represented the Association at the inauguration of President A. L. Pugsley of The Youngstown University on November 5, 1966.

Professor R. B. Deal, Oklahoma State University, represented the Association at the inauguration of President G. C. Cothen of Oklahoma Baptist University on November 5, 1966.

Professor Winston Massey, University of Chattanooga, represented the Association at the inauguration of President W. H. Masterson of the University of Chattanooga on November 4, 1966.

Professor H. E. Taylor, Florida State University, represented the Association at the inauguration of President S. W. Martin of Valdosta State College on November 15, 1966.

Northeast Missouri State Teachers College: Assistant Professor K. J. Stilwell, King's College, has been appointed Associate Professor; Mr. D. M. Norman has been promoted to Assistant Professor.

Purdue University: Dr. David Drasin, Cornell University, has been appointed Assistant Professor; Associate Professor R. E. Zink has been promoted to Professor.

University of Rochester: Dr. E. C. Curtis, of Daniel H. Wagner Associates, has been appointed Assistant Professor; Associate Professors N. G. Gunderson and R. A. Raimi have been promoted to Professors.

Texas Western College: Assistant Professor J. W. Fitzpatrick, Trinity University, has been appointed Assistant Professor; Mr. Lawrence Huntley has been promoted to Assistant Professor.

Westmar College: Mr. D. D. DeBoer has been promoted to Assistant Professor; Dr. D. L. Deever, Ohio State University, has been appointed Assistant Professor.

Associate Professor Jeanne Agnew, Oklahoma State University, has been appointed Visiting Associate Professor at Georgia State College.

Mr. G. J. Basil, Lehigh University, has been appointed Assistant Professor at Waynesburg College.

Dr. E. J. Beltrami, Grumman Aircraft Co., has been appointed Associate Professor at State University of New York at Stony Brook.

Mr. P. D. Blanchard, Wisconsin State University, has been promoted to Assistant Professor.

Mr. S. E. Clauss, Indiana Institute of Technology, has been appointed Assistant Professor at Purdue University.

Associate Professor R. M. Conkling, Highlands University, has been appointed Head of the Department of Physics and Mathematics and Director of the Computer Center.

Mrs. Hazel Cowin, Murray State University, has been promoted to Assistant Professor.

Assistant Professor Chester Feldman, Kent State University, has been promoted to Associate Professor.

Mr. D. E. Gracey, Shippensburg State College, has been promoted to Assistant Professor.

Mr. H. F. Hassenplug, Northwest Missouri State College, has been appointed Assistant Professor at Winthrop College.

Associate Professor Melvin Hausner, New York University, has been promoted to Professor.

Mr. S. E. Hunt, Rutgers—The State University, has been appointed Assistant Professor at State University College at Geneseo.

Professor Emeritus R. E. Bruce, Boston University, died on December 27, 1965. He was a Charter Member of the Association.

Professor Emeritus A. B. Coble, University of Illinois, died on December 8, 1966. He was a Charter Member of the Association.

Mr. L. A. Graham, Graham Transmissions, Inc., died in November, 1966. He was a member of the Association for eleven years.

Dr. C. L. Perry, Director of the Computation Facility at the University of California at San Diego, died in November, 1966. He was a member of the Association for seventeen years.

Professor Emeritus L. C. Plant, Michigan State University, died on November 12, 1966. He was a Charter Member of the Association.

MEMORIAL TO CARL FRIEDRICH GAUSS

This memorial, written originally in German for the lay reader in 1856 by a Goettingen colleague and close friend, is now available in English. The 85 page monograph contains source material on Gauss' life and achievements. It has been translated and privately printed by Miss Helen W. Gauss, great-granddaughter of Carl Friedrich, and is available in limited numbers, while the supply lasts, on remittance of $1.00 per copy to Colorado College Library, Colorado Springs, Colorado 80903.

Editorial Note. Professional mathematicians as well as laymen will be interested in the article "Mathematics: International Congress," by Lee Lorch, which appears in *Science* for February 24, 1967, pp. 1038–39.

MATHEMATICAL ASSOCIATION OF AMERICA

Official Reports and Communications

THE FIFTIETH ANNUAL MEETING OF THE ASSOCIATION

The Fiftieth Annual Meeting of the Mathematical Association of America was held in Houston, Texas, from Thursday to Saturday, January 26 to 28, 1967, in conjunction with the Annual Meeting of the American Mathematical Society and meetings of the National Council of Teachers of Mathematics and the Association for Symbolic Logic. The session of the Association on Saturday was a joint session with the National Council of Teachers of Mathematics. There were registered 3101 persons including 1720 members of the Association.

Sessions of the Association were held on Thursday morning and Friday morning in the Grand Ballroom of the Rice Hotel and on Saturday morning and afternoon in the Cullen Auditorium of the University of Houston. Presiding officers were Professors D. G. Bourgin on Thursday morning, Professor Jim Douglas, Jr. on Friday morning, Professor D. A. Johnson for the session on geometry and school mathematics and Professor F. B. Allen for the session on high school geometry, both on Saturday morning, Professor J. C. Egsgard for the session on school geometry of the future and Professor H. F. Fehr for the session on mathematics around the world, both on Saturday afternoon. The Program Committee for the meeting consisted of D. G. Bourgin, Chairman; Louis Brand, E. H. Connell, W. T. Guy, Jr., J. H. Hlavaty, E. C. Klipple, and W. K. McNabb.

FIRST SESSION OF THE ASSOCIATION

Session on Algebraic Topology

A Topological Study of Singularities of Varieties, by Professor A. H. Wallace, University of Pennsylvania.

Let D be a region of the plane bounded by arcs of algebraic curves. The set of real plane algebraic curves of a given order n having real points in D can be represented as a subset V of an algebraic variety W, bounded by subvarieties of W. V can then be decomposed into open sets V_i of subvarieties such that the points of any V_i represent curves homeomorphic under a homeomorphism of D onto itself, but these are not homeomorphic to curves represented by boundary points of V_i. Applied to curves with an isolated singularity in D, this gives a classification of singularities. A similar procedure can be applied to singularities of varieties of higher dimension.

Bordism and Periodic Maps, by Professor P. E. Conner, Jr., University of Virginia.

The application of bordism to the study of periodic diffeomorphisms of odd prime period on closed oriented manifolds is based upon the computation of the bordism module $\Omega(Z_p)$ together with a formula which uniquely determines the bordism class $[M^n]$ mod $p\Omega$ in terms of the normal bundle to the fixed point set of (T,M^n).

For maps of prime power period it can be shown that if (T,M^n) has no fixed points then $[M^n]$ is divisible by p, and an alternative proof of the Atiyah-Bott assertion that T cannot have exactly one fixed point can be given by these bordism techniques.

Isolated Singularities of Hypersurfaces, by Professor J. W. Milnor, Princeton University.

Consider an algebraic variety $\Gamma \subset C_n$ defined by one polynomial equation in n complex variables, $n \geq 2$. The topological behavior in the neighborhood of a singular point can be studied by intersecting Γ with a small sphere S_ϵ, centered at the singular point (Brauner, Hamburg Abh. 1928). If $n \neq 3$ then E. Brieskorn has constructed examples in which $\Gamma \cap S_\epsilon$ is a (knotted, sometimes exotic) topological sphere; and hence Γ is a topological manifold (*Proc. Nat. Ac. Sci.*, 1966, p. 1395). If $n=3$ then Γ cannot be a topological manifold unless it is completely non-singular (Mumford, I.H.E.S., Paris, Publ. Math. No. 9, 1961).

SECOND SESSION OF THE ASSOCIATION

Session on Analysis

The Nature of Quasi-Analyticity, by Professor Leon Ehrenpreis, Courant Institute.

One of the most interesting properties of an analytic function is the fact that if it vanishes on an open set, then it must vanish identically. One of the first generalizations of analyticity was in the direction of finding suitable classes of functions for which this uniqueness property, called quasi-analyticity, holds. Denjoy and Carleman studied classes C_M of indefinitely differentiable functions $f(x)$ defined by inequalities of the form

$$\left| f^{(n)}(x) \right| \leqq A^{n+1} M_n,$$

where $M = \{M_n\}$ is a sequence of positive numbers.

It is possible to generalize the Denjoy-Carleman theorem by replacing the operator d/dx, which is fundamental for their considerations, by an arbitrary constant coefficient partial differential operator.

Positive-Definite Functions on Groups, by Professor Edwin Hewitt, University of Washington.

Let G be a group. Let f be a complex-valued function on G. If the sum $\sum_{j=1}^{m} \sum_{k=1}^{m} \alpha_j \alpha_k f(x_j^{-1} x_k)$ is real and nonnegative for all subsets $\{x_1, \cdots, x_k\}$ of G and sequences $(\alpha_1, \cdots, \alpha_m)$ of complex numbers, f is called positive-definite. Such functions are intimately connected with unitary representations of groups, and play a key role in the original proof (1943) by Gel'fand and Raĭkov that locally compact groups have sufficiently many unitary continuous irreducible representations. A famous theorem of Herglotz-Bochner-Kreĭn-Weil characterizes continuous positive-definite functions on locally compact Abelian groups as Fourier-Stieltjes transforms. An analogue holds for arbitrary compact groups, as was proved by M. G. Kreĭn (1949). This address explored the structure of the algebra $\mathfrak{R}(G)$ of linear combinations of continuous positive-definite functions on a compact group G.

Annual Business Meeting of the Association; the Association's Sixth Award for Distinguished Service to Mathematics, and the Award of the 1967 Chauvenet Prize.

A Constructive Approach to Abstract Analysis, by Professor E. A. Bishop, University of California, San Diego.

Brouwer's criticisms of classical mathematics are just as valid as ever. On the positive side, we wish to give mathematics descriptive content by associating to every result a numerical interpretation. Every theorem should be an assertion that certain computations within the set of positive integers will produce certain results. This program is much easier to realize than is commonly supposed. Although most results of classical mathematics are proved with the aid of transcendent logical principles, such as the law of the excluded middle, it is usually (at least in the field of abstract analysis) possible to extract a kernel—quite a large kernel in most instances—of constructive truth.

THIRD SESSION OF THE ASSOCIATION

Joint Session with the National Council of Teachers of Mathematics

The lectures delivered in this part of the program have been published in a pamphlet

available from the National Council of Teachers of Mathematics, 1201 Sixteenth Street, N.W., Washington, D. C. 20036.

Session on Geometry and School Mathematics

Geometry in the United States, by Professor B. E. Meserve, University of Vermont.

Changes in the role and content of geometry in school mathematics curricula were identified and discussed with reference to general trends. The increased attention to geometric concepts at the elementary and junior high school levels illustrates a general recognition of the importance of geometry in mathematics curricula. The demise of the "sacred cow" attitude toward the first formal course in geometry (usually tenth grade) is part of a general breaking down of capsule approaches to several different branches of mathematics and the integration of all of these into a comprehensive mathematics curriculum in which geometry has a basic role.

The Ontario K–13 Geometry Report, by Professor H. S. M. Coxeter, University of Toronto.

The new curriculum in Ontario is expected to include geometry in each grade from Kindergarten to 13, because geometry develops and refines spatial intuition and has interactions with art as well as science. Moreover, geometry provides many opportunities for the student to exercise originality and ingenuity. Instead of an axiomatic treatment, the tendency is to use geometric transformations in an informal manner. For instance, *vector* is just another name for *translation*. Stereometry will begin in Kindergarten, because simple solids can be appreciated at an earlier age than their two-dimensional counterparts. By fitting suitable pieces together, the formula for the volume of a pyramid can be made very plausible.

Danish Geometry, by Professor P. S. Jorgensen, Carleton College.

The reform of secondary school geometry in the United States has for the most part centered on various attempts to preserve the geometry of Euclid by the introduction of the real numbers or by the adaptation of Hilbert's formulation of geometry. In Denmark, on the other hand, the reform has centered on the geometry of transformations (reflections, rotations, and translations). That such an approach is feasible in the beginning stages of geometry instruction is evidenced by some of the text books now in use in the Danish *real* school. The approach, though deductive in nature, is not a rigorous one, but instead is highly intuitive. A rigorous treatment is left to the *gymnasium* where the subject is closely tied to algebra.

This paper presented a brief summary of the Danish geometry program and gave some examples of how the geometry of transformations is adapted to the beginning geometry instruction.

British Geometry, by Professor Andrew Elliott, Royal Military College, Kingston, Ontario.

In the elementary school, ages 5 to 12, the Nuffield Mathematics Project places great emphasis on the formation of patterns with one or more basic elements, and on the symmetry properties of single geometric figures in both two and three dimensions. The School Mathematics Project and the Midland Mathematical Experiment in England and the Scottish Mathematics Group in Scotland for the 12–18 year old pupils use the fundamental transformations of translation, rotation and reflection to develop the properties of the triangle and the various parallelograms. From concrete examples in travel and navigation placed against a co-ordinate background these programs also develop vectors in two and three dimensions and use them in geometric proofs.

Session on High School Geometry

Synthetic Euclidean Geometry, by Professor Walter Prenowitz, Brooklyn College.

First, the position of synthetic Euclidean geometry in the present secondary curriculum was considered. Improved treatments of tenth grade geometry have been developed and are available for classroom use which should be stimulating and challenging to the mathematics major and the liberal arts student. Second, synthetic geometry and coordinate geometry were compared and their individual advantages described. Third, the role of synthetic geometry in the secondary curriculum was discussed, particularly its advantages as a model of the deductive organization of a body of knowledge and as a medium for presenting the relation of mathematical theory to physical reality.

Affine Geometry, by Professor G. P. Johnson, Oakland University.

In 1964 a writing team sponsored by the National Science Foundation and Wesleyan University prepared materials in metric geometry for use in high schools. Two years of class testing since then support the belief that such content can provide, at least for able students, a significantly more satisfactory course than those following traditional lines.

Vector Geometry, by Professor H. E. Vaughan, University of Illinois, Urbana.

This report concerns a two-year secondary school course in process of development and testing by UICSM since September 1963. The course presupposes a year of algebra, and is designed for able students. After spending some time developing intuitive notions concerning translations, euclidean geometry is presented as the theory of a vector space—the space of translations—*operating on* a set of points—the points of euclidean space. There are three postulates which formulate the way in which translations operate on points, followed by the usual postulates for a 3-dimensional inner product space over the real numbers. For more details, see Steven Szabo, An Approach to Euclidean Geometry Through Vectors, *The Mathematics Teacher*, vol. 59 (1966), pp. 218–235.

Geometric Transformations, by Professor Seymour Schuster, University of Minnesota.

Thoughts concerning the introduction of geometric transformations into high school mathematics are becoming more prevalent. There are several strong reasons that justify a move in this direction. (1) The ideas of congruence can be given a mathematically sound treatment by means of transformations, whereas a treatment based on superposition (still taught in many quarters) is totally unsatisfactory. (2) A use of transformations in geometry reiterates and uses what is—or at least should be—one of the basic themes of the new mathematics programs: the notion of function. (3) Transformations, *per se*, are important tools which will serve students throughout their entire mathematical lives. They are "tricks of the trade" for problem-solving at all levels; they are indispensable in both the pure and applied work in fields such as differential equations and complex variable; they are the key to understanding symmetry; finally, they are used to answer, in the sense of Felix Klein, the question "What is geometry?"

Session on School Geometry of the Future

Cambridge Committee View, by Professor E. E. Moise, Harvard University.

There were two Cambridge Conference views described in the CCSM report, one algebraic and "modern," the other more classical. In support of the classical (minority) view, the following points were made:

1. In a choice of content and style, at a given teaching level, a fundamental criterion is the availability of challenging and workable problems. At low maturity levels, calculus and classical geometry outrank linear algebra and transformation groups under this criterion.

2. A vectorial conception of geometry is on a high level of abstraction, because one cannot significantly say of a point that it is a vector; the significant statement is that a space (considered as an entity in itself) is a vector space.

Topology, by Professor G. S. Young, Tulane University.

A discussion of various natural topics in Topology that could be introduced in the school curriculum was given. Examples include such concepts as orientation, separation properties, surfaces, and what are characteristics. The very tentative notion of such ideas in the speaker's mind was stressed.

Projective Geometry, by Professor C. E. Springer.

The speaker described a series of 32 lectures on analytic projective geometry, which he gave in the summer of 1966 to a class of 40 high school students selected from 19 states. This was part of a program sponsored by the National Science Foundation at the University of Oklahoma. The material consisted of the first three chapters of Dorwart's "The Geometry of Incidence," Prentice-Hall, 1966, and of selected topics and exercises from the speaker's "Geometry and Analysis of Projective Spaces," Freeman, 1964. After a treatment of homographies on a line, the concepts of

join, intersection, and incidence in the plane were introduced with a view toward solution of problems on linkages, point loci, line envelopes, and invariance under projective mappings.

Session on Mathematics Around the World

A panel discussion with Dr. J. H. Hlavaty, New Rochelle, New York, Professor Mariano Garcia, Jr., University of Puerto Rico, and Mr. Henry Swain, New Trier Township High School, Winnetka, Illinois.

Dr. Hlavaty spoke on mathematics education in Europe and England, specifically on the two-way international contacts in mathematics education, from Royaumont (1959) to the NCTM Soviet Tour and the U.S.-U.K. Conference (1966). Many western European countries have made bold changes in their programs of secondary education. These changes are inspiring new experiments in this country in the second round of curriculum experimentation. In the Soviet Union and the eastern countries changes in programs have been later in coming than in the U.S.A., and the "new" ideas (sets, structures, mappings, vectors, etc.) are being introduced slowly and without fanfare. A significant contribution of the English experiments (and some of the European ones) come in geometry—with emphasis on transformations rather than on attempts at refining the logical presentation of Euclidean geometry.

Professor Garcia spoke on the reform in mathematical education in Central and South America. For the past four years, there have been concerted efforts in Central America to improve the mathematics programs in the countries of that area. This is in line with some of the major recommendations made in the Second Inter-American Conference on Mathematical Education held in Lima, Peru, last December. These recommendations include: to stimulate the creation of teaching and research mathematics centers; to foster interchange activities of universities; to encourage the organization of national and regional mathematics associations, conferences and symposia; and to promote the publication of materials that will upgrade the mathematical level of the various countries represented.

Mr. Swain reported on projects for improvement of mathematical education in some of the countries of Africa. For five summers a group of about 60 African, British, and American mathematicians has met in Entebbe, Uganda, and then in Mombasa, Kenya, to help improve the teaching of mathematics in ten English speaking countries across middle Africa. Administered by Educational Services Incorporated and paid for by the U. S. Agency for International Development, the workshops have produced a quantity of textbook material for primary, secondary, and teacher training schools. Teacher training institutes have also been conducted. There will probably be two more summers of writing. Several other mathematics projects are in progress in various African countries, most of them stimulated by the Entebbe Mathematics Project, some by the School Mathematics Project of England.

SPECIAL SESSIONS OF THE ASSOCIATION

Film showings were held in the Crystal Ballroom of the Rice Hotel as follows: on Wednesday at 7:00 P.M., "John von Neumann" (a CEM Individual Lectures Production in b & w), at 8:10 P.M., "Can You Hear the Shape of a Drum? A Lecture by Mark Kac" (a CEM Individual Lectures Production in color); on Thursday at 7:00 P.M., "Pits, Peaks, and Passes (Part I), A Lecture on Critical Point Theory by Marston Morse" (a CEM Individual Lectures Production in color), at 8:00 P.M., CEM Animated Calculus Films (in color) including "Volumes by Shells," by George Leger, "Limits" by Robert C. Fisher, "Newton's Method" by Herbert S. Wilf, "What is Area" by Charles E. Rickart, "Area Under a Curve" by Charles E. Rickart, and "The Definite Integral" by Robert C. Fisher; on Friday at 7:00 P.M., CEM Animated Level I Films (in color) including "What is a Set?," "One-to-One Correspondence," "Counting," "Union and Intersection," "Addition and Subtraction," and "Multiplication and Division," at 8:10 P.M. Films of the College Geometry Project of the University of Minnesota (in color) including

"Orthogonal Projection" by Daniel Pedoe, "Central Similarities" by Daniel Pedoe, "Dihedral Kaleidoscopes" by H. S. M. Coxeter, "Geometric Vectors" by Wm. O. J. Moser and S. Schuster, "Inversion" by Daniel Pedoe, "Curves of Constant Width" by J. D. E. Konhauser, and "Central Perspectivities" by S. Schuster. There was also a special showing of the films of the College Geometry Project on Friday at 1:00 P.M.

MEETING OF THE BOARD OF GOVERNORS

The Board of Governors of the Association met on Wednesday morning and afternoon in the Directors Room of the Rice Hotel, with 40 members present.

The Board approved the appointment by President Wilder of the following Nominating Committee for 1967: R. H. Bing, Chairman; P. T. Bateman, and O. G. Harrold.

The Board elected Professor R. J. Walker as Second Vice-President of the Association for the two-year term 1967–1968. Since Professor R. A. Rosenbaum, as Editor of the MONTHLY, will automatically become a member of the Board, his term as governor was, with his approval, considered terminated at the end of the Houston meeting, and the Board elected Professor R. G. Bartle of the University of Illinois, Urbana, as his replacement for the unexpired part of his term extending through 1967.

The Board elected Professor Haskell Cohen as an additional Associate Editor of the MONTHLY and Professor R. W. Bagley as an additional Associate Editor of the MATHEMATICS MAGAZINE.

The Board approved in principle proposals to the National Science Foundation by the Individual Lectures Project for continued support of the project for the two-year period starting June 1, 1967, and by the Committee on the Undergraduate Program in Mathematics for continued support of the Committee for the two-year period starting July 1, 1967.

The Board approved that, effective at once, payment of the usual $2.00 initiation fee is waived for all full-time graduate students whose application blanks are properly certified.

The Board approved the following schedule of future meetings of the Association: University of Toronto, August 28–30, 1967; San Francisco, California, January 25–27, 1968; University of Wisconsin, Madison, August 26–28, 1968; New Orleans, Louisiana, January, 1969; University of Oregon, August 25–27, 1969; Miami, Florida, January 24–26, 1970.

The Executive Director reported the membership of the Association as 17,530 individual members, an increase of 816 since the corresponding date last year, 2 corporate members, and 236 academic members.

The Board passed a number of resolutions in which it expressed its deep concern regarding the severe curtailment and threatened complete termination by the National Science Foundation of several projects vital to the maintenance of present levels of mathematical education in this country, specifically, the visiting lectureship program, the academic year institutes for secondary school teachers of science and mathematics, and other similar programs. These resolutions appear on pp. 473–475 of this issue.

ANNUAL BUSINESS MEETING OF THE ASSOCIATION

The annual Business Meeting was held on Friday, January 27, 1967, in the Grand Ballroom of the Rice Hotel, with First Vice-President Young presiding. The Association's Sixth Award for Distinguished Service to Mathematics was made to Professor W. L. Duren, Jr. of the University of Virginia. The citation (which appeared on pages 1–2 of the January issue of this MONTHLY) was prepared and read by Professor E. J. McShane of the University of Virginia; the Award was presented by First Vice-President Young. Professor Duren, in accepting the Award, expressed his pleasure in having been voted

this Award which he honored as a symbol that the Association is committed to the principle of service complementing natural attitudes toward private motivation in our work. He thought this to be an exciting time in our history in that the Association has been brought into the plans for the expansion of science and, in particular, mathematical science because of its dedication to service. He foresaw a great enlargement of the service of the Association as a fruition of its past endeavours. He concluded: "If I have had, or I can have, any part in this, it is a most happy and joyful thing, and I certainly thank you all for the Award which I shall cherish for the rest of my life."

The 1967 Chauvenet Prize was awarded to Professor G. L. Weiss of Washington University for his paper "Harmonic Analysis," published in *MAA Studies in Mathematics*, Volume 3 (1965) 124–178. The Award was presented by First Vice-President Young. (For further details on this Award, see the January issue of this MONTHLY, page 2.)

The Secretary then announced the results of the balloting for officers in which 2112 votes were cast: Professor Victor Klee of the University of Washington and Professor N. H. McCoy of Smith College were elected governors for the three-year term 1967–69.

The Secretary announced that the book APPLICATIONS OF UNDERGRADUATE MATHEMATICS IN ENGINEERING by Ben Noble is now available. MAA Studies Volume 4, *Studies in Global Geometry and Analysis*, edited by S. S. Chern, is now scheduled for publication in July 1967. The brochure YOU'LL NEED MATH, written by Leonard Gillman and prepared with a grant from the National Science Foundation, is now available from the Buffalo office of the Association. It is directed to junior high school students and gives information on the amount of mathematics needed in a great variety of careers. Large scale free distribution of this brochure is now being planned.

The Secretary then reported on some of the actions taken by the Board of Governors on Wednesday. In reference to the meeting to be held this summer at the University of Toronto, he announced that the committee on arrangements there had reserved rooms at Loyola College in Montreal for those desiring to visit Expo 67 either before or after the meeting for the following nights: August 25–27 and September 1–3. The rates will be $7 per person for a double room and $8 per person for a single room. Early reservation of these rooms is advised. Those interested in making reservations at Loyola College should write as soon as possible to: Reservations, Department of Mathematics, University of Toronto, Toronto 5, Ontario, Canada.

The Secretary then expressed, on behalf of the Association and himself personally, deep appreciation to Professor J. W. Green, the retiring Secretary of the American Mathematical Society, for all his efforts and special consideration shown to the Association in the joint endeavors in which the Society and Association are engaged, specifically the planning of their joint national meetings. He also expressed the Association's gratitude to the University of Houston for its sponsorship of the cocktail and beer party on Wednesday evening and for providing the free bus transportation between the Rice Hotel and the University of Houston on Saturday. He conveyed special thanks to Professor D. R. Traylor, the Chairman of the Committee on Arrangements, for coordinating so successfully the many activities requiring his attention.

The Secretary then moved an amendment to the By-Laws which, effective with the 1968 dues, will increase the dues of individual members from $6 to $8. The motion was approved without dissent.

MEETINGS OF OTHER ORGANIZATIONS

The American Mathematical Society held sessions from Tuesday, January 24, to Friday, January 27. The fortieth Josiah Willard Gibbs Lecture was delivered by Professor Mark Kac of the Rockefeller University on Tuesday evening at 8:00 P.M. in the Grand Ballroom of the Rice Hotel on "Some Mathematical Problems in the Theory of

Phase Transitions." Professor P. J. Cohen of Stanford University delivered an address entitled "The Modern Development of Axiomatic Set Theory" on Tuesday at 2:00 P.M.; Professor Alex Heller of the City University of New York gave an address on "Stable Homotopy Categories" on Thursday at 2:00 P.M. and Professor B. H. Neumann of the Australian National University and the University of Wisconsin delivered a lecture on "Varieties of Groups" on Friday at 2:00 P.M.

The Cole Memorial Prize of the Society was awarded to Professors J. B. Ax and S. B. Kochen of Cornell University for their sequence of three papers on Diophantine problems over local fields: "Diophantine Problems over Local Fields I," *Amer. J. Math.*, 87 (1965) 605–630; "Diophantine Problems over Local Fields II. A Complete Set of Axioms for p-adic Number Theory," *Amer. J. Math.*, 87 (1965) 631–648, and "Diophantine Problems over Local Fields III. Decidable Fields," *Annals of Math.*, 83 (1966) 437–456.

The Association for Symbolic Logic met on Monday and Tuesday, January 23 and 24. Professor Georg Kreisel of Stanford University gave an invited address on "A Survey of Proof Theory" on Monday at 11:00 A.M., Professor G. E. Sacks of Cornell University and the Massachusetts Institute of Technology one on "Recent Developments in and Applications of the Theory of Degrees" on Monday at 2:00 P.M., and Professor R. M. Solovay of the University of California, Berkeley, one on "Large Cardinals" on Tuesday at 11:00 A.M.

A brief report on the proposals and recommendations of the Cambridge Conference of Training Teachers of Mathematics was given on Thursday at 6:45 P.M. Professor J. W. Green chaired the meeting, and Professor George Springer spoke about the proposals and recommendations.

ARRANGEMENTS, ENTERTAINMENT AND RECREATION

The Committee on Arrangements for the meeting consisted of D. R. Traylor, Chairman; Mrs. Eleanor Akers, H. L. Alder, P. T. Bateman, M. L. Curtis, W. T. Ingram, C. B. Rader, J. A. Robinson, G. L. Walker, Mrs. Margaret R. Wiscamb, Martin Wright.

Registration headquarters were located in the Grand Foyer on the second floor of the Rice Hotel on Monday through Friday. On Saturday the registration desk was moved to the Cullen Auditorium on the campus of the University of Houston. Accommodations for the meeting were handled by the greater Houston Convention and Visitors Council.

The University of Houston was host at a cocktail and beer party in the Grand Ballroom of the Rice Hotel on Wednesday from 9:00 P.M. until midnight to which all members of the participating organizations were invited.

HENRY L. ALDER, *Secretary*

RESOLUTIONS VOTED BY BOARD OF GOVERNORS

The following three resolutions were approved by the Board of Governors at its meeting on January 25, 1967, in Houston, Texas:

1. A Resolution addressed to the Congress of the United States and the officers of the National Science Foundation.

Whereas, much of the dramatic improvement in science education in the United States in the past decade can be ascribed directly to a significant increase in the concern for education on the part of the scientific community,

Whereas, a real and direct manifestation of this concern has been the fact that financial support for these national efforts toward curriculum reform has come largely from the National Science Foundation, an agency which is, in a genuine sense, part of the scientific community,

Whereas, through these years of support and leadership in this area, the National

Science Foundation has developed many effective programs for aiding and improving science education,

Whereas, comparable programs of support of science education at every level do not exist in any of the other granting agencies of the Federal Government, and

Whereas, the future of science in the United States depends as much on the education of the scientists of tomorrow as on the research of the scientists of today,

THEREFORE BE IT RESOLVED that the Board of Governors of the Mathematical Association of America

strongly urges the Congress of the United States and the officers of the National Science Foundation, even in the face of the present extraordinary pressures on the National Budget, to consider carefully the importance to our national welfare of continued and even increased support of science education,

strongly urges the Congress to continue directing this support of science education through the National Science Foundation rather than through other agencies which are not similarly parts of the scientific community, and

strongly urges the officers of the National Science Foundation, even in the face of the growing need for funds in support of research, to consider carefully the importance to science in our nation of continued and even increased support of science education by the National Science Foundation.

2. A Resolution addressed to the National Science Foundation.

The Mathematical Association of America calls attention to a National Science Foundation program whose future success is threatened by decreasing support.

The Mathematical Association of America has operated, with National Science Foundation support, its program of visiting lecturers for colleges since 1953. There is overwhelming evidence that this program has played a significant role in the improvement of instruction in mathematics which has occurred in the last fifteen years. The funds now provided for operating this program are inadequate to meet the costs of the program. The colleges visited contribute several thousand dollars each year, but NSF does not permit the use of these funds to pay the costs of the program. Although the program of visiting lecturers for colleges is as badly needed as ever—especially because of rapidly increasing enrollments, the expansion in the number of two-year colleges, and the continuing shortage of qualified instructors—the program is suffering because of inadequate support by NSF. Unless support can be returned to a more adequate level, the Mathematical Association of America may be forced to discontinue its operation of the program because it has become a drain on its own limited resources.

The Mathematical Association of America, meeting in Houston, Texas on January 25, 1967, commends the National Science Foundation for the success of its programs in the past and urges that it use every means possible to continue its support of mathematics and mathematical education. In particular, the Association hopes that NSF will continue its program of visiting lecturers for colleges and will provide adequate levels of support for this program.

3. A Resolution addressed to the Congress of the United States and the officers of the National Science Foundation.

Whereas, there is currently a great shortage of adequately trained college teachers of mathematics, due to the phenomenal increase in the number of two-year colleges with inadequately trained staffs, the rapidly increasing number of college students taking mathematics, and the drastic curriculum changes recommended by the Committee on the Undergraduate Program in Mathematics, and

Whereas, institutes have proved highly valuable in improving instruction in high schools and in colleges, and appear to be the only known means of effectively reaching a significantly large number of in-service teachers, and

Whereas, the number of institutes for college teachers of mathematics supported by NSF is totally inadequate to meet current needs, and

Whereas, there is little likelihood that funds for supporting institutes can be obtained from private sources, and

Whereas, it is in the national interest to maintain and increase the quality of mathematics instruction in our two-year and four-year colleges,

THEREFORE BE IT RESOLVED that the Board of Governors of the Mathematical Association of America strongly recommends that the Federal Government through the National Science Foundation make available the necessary funds to support a greatly increased program of unitary and sequential institutes for college teachers of mathematics.

The need for institutes for teachers in two-year colleges is particularly acute. The staffs of these institutions—and their number is increasing at an astonishing rate—are being recruited largely from the ranks of high school teachers, many of whom are not prepared to teach college level mathematics. It appears that mathematics instruction in two-year colleges may be the weakest link in the whole range of mathematics education.

Also, as the attached statistics (see table below) supplied by the National Education Association shows, there is currently and in prospect a significantly greater shortage of qualified college teachers of mathematics than in the biological and physical sciences.

These facts suggest that institutes for college teachers of mathematics, particularly teachers in two-year colleges, merit high priority in the allocation of federal funds for education.

VARIOUS INDICES OF SHORTAGES OF COLLEGE TEACHERS BY FIELDS

	Biological Sciences	*Chemistry*	*Physics*	*Physical Sciences*	*Mathematics*
Percentage of new teachers with Doctor's degrees, colleges and universities, 1964–65	50.2			59.1	28.2
Percentage of new teachers with Master's degrees or less, colleges and universities, 1964–65	29.3			27.2	51.1
Percentage of new teachers with less than a Master's degree, junior colleges 1963–64 and 1964–65	12.1	14.9	19.9		17.3
Number of colleges reporting critical shortage of qualified teachers in 1963–64 and 1964–65	167	191	406		597
Number of colleges foreseeing more acute shortage of qualified teachers	120	195	362		508
Number of budgeted positions unfilled in colleges and universities, 1963–64 or 1964–65	50	51	110		166
Number of junior colleges reporting a shortage of qualified teachers in 1963–64 and 1964–65	30	105	132		159
Number of junior colleges foreseeing a future shortage of qualified teachers	30	92	120		178

ACADEMIC MEMBERS ELECTED INTO THE ASSOCIATION

In accordance with the amendments adopted at the business meeting of the Association at Stillwater on August 30, 1961, the Board of Governors at its meeting at Houston, Texas, on January 25, 1967, elected to membership in the Association the eleventh set of applicants for academic membership (for election of the other ten sets, see the April and November issues for 1962–66). Approval for election to membership was given to the following 6 applicants for academic membership:

Bowling Green State University
University of California, Irvine
Chamberlayne Junior College, Boston, Massachusetts
University of Hawaii
Mount Holyoke College
Rhode Island Junior College, Providence, Rhode Island

HENRY L. ALDER, *Secretary*

OFFICERS AND COMMITTEES AS OF FEBRUARY 1, 1967

General Offices: SUNY at Buffalo, Buffalo, New York, 14214
Executive Director: H. M. GEHMAN

OFFICERS

President, E. E. MOISE, Harvard University (1967–68)
Past-President, R. L. WILDER, University of Michigan (1967)
First Vice-President, G. S. YOUNG, Tulane University (1966–67)
Second Vice-President, R. J. WALKER, Cornell University (1967–68)
Editor, R. A. ROSENBAUM, Wesleyan University (1967–71)
Secretary, H. L. ALDER, University of California, Davis (1965–69)
Treasurer, H. M. GEHMAN, SUNY at Buffalo (1963–67)
Associate Secretary, RAOUL HAILPERN, SUNY at Buffalo (1963–67)

ADDITIONAL MEMBERS OF THE BOARD OF GOVERNORS

Ex-Presidents

R. H. BING, University of Wisconsin, Madison (1965–70)
A. W. TUCKER, Princeton University (1963–68)
R. L. WILDER, University of Michigan (1967–72)

Elected Members of the Finance Committee

E. A. CAMERON, University of North Carolina (1966–69)
G. B. PRICE, University of Kansas (1964–67)

Governors at Large

R. G. BARTLE, University of Illinois, Urbana (1967)
P. S. JONES, University of Michigan (1965–67)
VICTOR KLEE, University of Washington (1967–69)
N. H. MCCOY, Smith College (1967–69)
C. R. PHELPS, National Science Foundation (1966–68)
M. F. SMILEY, University of California, Riverside (1966–68)

Sectional Governors (July 1, 1964–June 30, 1967)

Kansas, CALVIN FOREMAN, Baker University
Missouri, J. J. ANDREWS, St. Louis University
New Jersey, L. F. MCAULEY, Rutgers—The State University

Northeastern, D. E. CHRISTIE, Bowdoin College
Ohio, WADE ELLIS, Oberlin College
Pacific Northwest, A. T. LONSETH, Oregon State University
Southeastern, J. R. WESSON, Vanderbilt University
Southwestern, HARVEY COHN, University of Arizona
Upper New York State, D. E. KIBBEY, Syracuse University

Sectional Governors (July 1, 1965–June 30, 1968)

Illinois, J. M. H. OLMSTED, Southern Illinois University
Iowa, D. W. WALL, State University of Iowa
Louisiana-Mississippi, P. K. REES, Louisiana State University
Maryland-D.C.-Virginia, DOROTHY L. BERNSTEIN, Goucher College
Michigan, K. W. FOLLEY, Wayne State University
Minnesota, E. J. CAMP, Macalester College
Philadelphia, EMIL GROSSWALD, University of Pennsylvania
Southern California, R. C. JAMES, Harvey Mudd College
Texas, MARTIN WRIGHT, University of Houston

Sectional Governors (July 1, 1966–June 30, 1969)

Allegheny Mountain, A. F. STREHLER, Carnegie Institute of Technology
Indiana, G. N. WOLLAN, Purdue University
Kentucky, L. L. SCOTT, University of Louisville
Metropolitan New York, ABRAHAM SCHWARTZ, City University of New York
Nebraska, D. W. MILLER, University of Nebraska
Northern California, D. W. BLAKESLEE, San Francisco State College
Oklahoma, R. B. DEAL, Oklahoma State University
Rocky Mountain, F. M. STEIN, Colorado State University
Wisconsin, C. J. VANDERLIN, JR., University of Wisconsin, Madison

COMMITTEES OF THE ASSOCIATION

Terms of office of members expire, except where otherwise noted, at the Annual Meeting in January following the last year of service listed below. For temporary committees, no terms of office are listed, since they are automatically discharged at the expiration of the President's term of office, which is the Annual Meeting in January, 1969.

EXECUTIVE COMMITTEE

E. E. MOISE, *Chairman* (1966–69); H. L. ALDER (1965–69), H. M. GEHMAN (1963–67), R. A. ROSENBAUM (1967–71), R. J. WALKER (1967–68), R. L. WILDER (1964–67), G. S. YOUNG (1966–67), all *ex officio*.

FINANCE COMMITTEE

E. E. MOISE, *Chairman* (1967–68), *ex officio;* E. A. CAMERON (1966–69), G. B. PRICE (1964–67), H. L. ALDER (1965–69), *ex officio*, H. M. GEHMAN (1963–67), *ex officio*.

COMMITTEE ON ADVISEMENT AND PERSONNEL

A. B. WILLCOX, *Chairman* (1967–69); K. J. ARNOLD (1966–68), E. A. DAVIS (1967–69), J. S. FRAME (1967), Mrs. F. J. MACWILLIAMS (1967–69), C. R. PHELPS (1967–68), W. H. SCHMIDT (1966–68).

COMMITTEE ON AN INTERNSHIP PROGRAM IN MATHEMATICS EDUCATION

ROY DUBISCH, *Chairman;* MAX BEBERMAN, D. E. CHRISTIE, E. E. MOISE.

COMMITTEE ON EARLE RAYMOND HEDRICK LECTURES

E. E. FLOYD, *Chairman* (1965–67); N. J. FINE (1967–69), C. B. MORREY (1966–68).

COMMITTEE ON EDUCATIONAL MEDIA

C. O. OAKLEY, *Chairman* (1966–69); A. A. BLANK (1967–68), E. A. CODDINGTON (1966–68), L. W. COHEN (1967–69), LEON HENKIN (1965–67), J. H. HLAVATY (1965–67), P. S. JONES (1967–69), C. E. RICKART (1965–67), SEYMOUR SCHUSTER (1967–69), GEORGE SPRINGER (1966–68), F. B. WRIGHT (1965–67).

Advisory Committee for Calculus Films: H. M. MACNEILLE, *Director* (1965–67); J. H. CURTISS (1965–67), S. B. JACKSON (1965–67), C. B. MORREY (1967–69), A. W. TUCKER (1967–69).

Advisory Committee for Individual Lecture Films: L. B. WILLIAMS, *Director* (1965–67), R. C. BUCK (1965–67), L. W. COHEN (1965–67), P. D. LAX (1965–67), B. J. PETTIS (1967–69).

Advisory Committee for Level I Films: C. B. ALLENDOERFER, *Director* (1965–67); N. J. FINE (1965–67), LEON HENKIN (1965–67), J. H. HLAVATY (1965–67), P. S. JONES (1965–67), E. P. VANCE (1965–67), G. C. WEBBER (1965–67), F. B. WRIGHT (1965–67).

Advisory Committee for Programed Learning: B. H. GERE, *Director* (1965–67); D. W. BLAKESLEE (1965–67), LEONARD GILLMAN (1965–67), ROBERT KALIN (1965–67), A. B. MEWBORN (1965–67), L. W. SMITH (1965–67).

Subcommittee on Television: P. S. JONES, *Chairman;* C. B. ALLENDOERFER, R. C. FISHER.

COMMITTEE ON HIGH SCHOOL CONTESTS

Terms of office of members of this committee expire on August 31 of the last year of service listed.

C. T. SALKIND, *Chairman* (1966–69); W. H. FAGERSTROM, *Director*, L. C. DALTON (1965–68), J. M. EARL (1965–68), HARRISON GIVENS, JR. (1966–69), N. S. MENDELSOHN (1965–68), HANS SAGAN (1964–67), E. E. STROCK (1964–67).

COMMITTEE ON INSTITUTES

D. L. THOMSEN, JR., *Chairman* (1967–69); D. K. HARRISON (1966–68), MARK KAC (1967–69), JOSEPH LANDIN (1966–68), V. O. MCBRIEN (1966–69), E. R. MULLINS (1966–68).

COMMITTEE ON PUBLICATIONS

R. P. BOAS, *Chairman* (1967–69); JOSHUA BARLAZ (1967–69), H. S. M. COXETER (1965–67), MARY P. DOLCIANI (1966–68), DAVID GALE (1967–69), WALLACE GIVENS (1965–67), I. I. HIRSCHMAN, JR. (1966–68), IVAN NIVEN (1966–68), OLGA TAUSSKY (1966–68), ROY DUBISCH (1964–68), *ex officio*, H. M. GEHMAN (1963–67), *ex officio*, R. A. ROSENBAUM (1967–71), *ex officio*.

Subcommittee on Carus Monographs: IVAN NIVEN, *Chairman* (1966–68); R. P. BOAS (1967–69), OLGA TAUSSKY (1966–68).

Subcommittee on Ford Awards: R. P. BOAS, *Chairman* (1967–69), *ex officio:* C. W. CURTIS (1966–68), R. P. DILWORTH (1965–67).

Subcommittee on MAA Studies in Mathematics: WALLACE GIVENS, *Chairman* (1965–67); H. S. M. COXETER (1965–67), DAVID GALE (1967–69).

Subcommittee on Slaught Papers: I. I. HIRSCHMAN, JR., *Chairman* (1966–68); JOSHUA BARLAZ (1967–69), MARY P. DOLCIANI (1966–68), R. A. ROSENBAUM (1967–71), *ex officio*.

Subcommittee on Miscellaneous Publications: R. P. BOAS, *Chairman* (1967–69); H. L. ALDER (1966–69), H. M. GEHMAN (1966–67), all *ex officio.*

COMMITTEE ON SECONDARY SCHOOL LECTURERS

H. M. GELDER, *Chairman* (1965–67); H. M. BACON (1967–69), D. R. BEY (1965–67), B. H. BISSINGER (1966–68), J. N. EASTHAM (1967–69), H. V. HUNEKE (1965–67), J. H. WAHAB (1967–69).

COMMITTEE ON SECTIONS

L. E. MEHLENBACHER, *Chairman* (1967–70); E. M. BEESLEY (1965–68), W. T. FISHBACK (1967–70), M. E. MUNROE (1964–67), ARNOLD WENDT (1966–69), RAOUL HAILPERN (1963–67), *ex officio.*

COMMITTEE ON THE AWARD FOR DISTINGUISHED SERVICE TO MATHEMATICS

G. B. PRICE, *Chairman* (1965–67); W. L. DUREN, JR. (1967–69), H. M. GEHMAN (1966–68).

COMMITTEE ON THE CHAUVENET PRIZE

VICTOR KLEE, *Chairman* (1965–67); SAMUEL EILENBERG (1966–68), G. L. WEISS (1967–69).

COMMITTEE ON THE FUTURE ADMINISTRATIVE STRUCTURE OF THE ASSOCIATION

E. A. CAMERON, *Chairman;* R. C. BUCK, H. O. POLLAK, R. A. ROSENBAUM, A. W. TUCKER.

COMMITTEE ON THE PREPARATION OF A 50-YEAR HISTORY OF THE ASSOCIATION

K. O. MAY, *Chairman;* C. B. BOYER, D. J. STRUIK

COMMITTEE ON THE PUTNAM PRIZE COMPETITION

R. E. GREENWOOD, *Chairman* (1965–67); J. H. MCKAY, *Director* (1965–67), N. D. KAZARINOFF (1966–68), LEO MOSER (1967–69).

COMMITTEE ON THE UNDERGRADUATE PROGRAM IN MATHEMATICS

RICHARD D. ANDERSON, *Chairman* (1965–67); DOROTHY L. BERNSTEIN (1967–69), L. W. COHEN (1966–68), M. L. CURTIS (1965–67), C. R. DEPRIMA (1965–67), M. D. DONSKER (1967–69), D. T. FINKBEINER II (1967–69), LEONARD GILLMAN (1965–67), D. B. GOODNER (1966–69), H. J. GREENBERG (1967–69), I. N. HERSTEIN (1967–69), M. GWENETH HUMPHREYS (1965–67), L. J. PAIGE (1965–67), ALEX ROSENBERG (1966–68), R. M. THRALL (1965–68), A. B. WILLCOX (1966–68), G. S. YOUNG (1965–68), LEO ZIPPIN (1967–69), E. G. BEGLE, *ex officio,* E. E. MOISE (1967–68), *ex officio.*

Advisory Group on Applications of Mathematics: M. D. DONSKER, *Chairman* (1967–68).

Advisory Group on Communications: A. B. WILLCOX, *Chairman* (1966–68); C. R. DEPRIMA (1966–67), R. M. THRALL (1966–67).

Panel on College Teacher Preparation: LEONARD GILLMAN, *Chairman* (1966–68); C. E. BURGESS (1966–68), D. W. BUSHAW (1966–68), D. E. CHRISTIE (1966–68), L. W. COHEN (1966–68), D. T. FINKBEINER II (1966–68), MEYER JERISON (1966–68), HERMAN MEYER (1966–68), ALEX ROSENBERG (1966–68), E. H. SPANIER (1966–68), J. H. WELLS (1966–68).

Panel on Computing: H. J. GREENBERG, *Chairman.*

Panel on Mathematics for the Life Sciences: R. M. THRALL, *Chairman* (1967–69).

Panel on Mathematics in Two-Year Colleges: D. B. GOODNER, *Chairman* (1966–69), JOSHUA BARLAZ (1966–69), L. J. DUNHAM (1966–68), J. N. EASTHAM (1966–67), M. GWENETH HUMPHREYS (1966–67), R. C. JAMES (1966–68), CAROL H. KIPPS (1966–68), B. E. MESERVE (1966–68), J. W. METTLER (1966–67), R. Z. NORMAN (1966–68), W. R. RICE (1966–69).

Panel on Statistics: H. O. POLLAK, *Chairman* (1967–69).

Panel on Teacher Training: G. S. YOUNG, *Chairman* (1967–68); E. G. BEGLE (1965–67), MARY FOLSOM (1966–67), C. E. HARDGROVE (1966–68), E. R. KOLCHIN (1966–68), GEORGE SPRINGER (1966–68), S. S. WILLOUGHBY (1966–68).

COMMITTEE TO STUDY THE REORGANIZATION OF ASSOCIATION JOURNALS

DOROTHY L. BERNSTEIN, *Chairman;* D. W. BLAKESLEE, D. E. CHRISTIE, C. R. PHELPS, G. S. YOUNG.

COMMITTEE ON VISITING LECTURERS

R. E. GASKELL, *Chairman* (1965–67); E. M. BEESLEY (1966–68), R. D. BOSWELL, JR. (1966–69), W. K. MOORE (1966–68), M. W. POWNALL (1965–67), J. R. WESSON (1966–67), W. L. WILLIAMS (1966–68).

JOINT COMMITTEE ON EMPLOYMENT OPPORTUNITIES

Terms of office of members of this committee expire on February 28 of the last year of service listed.

D. R. MORRISON, *Chairman* (1964–68, MAA); M. L. HENRIKSEN (1966–70, AMS), G. S. JONES (1966–67, SIAM).

JOINT COMMITTEE ON PLACES OF MEETINGS

G. L. WALKER, *Chairman;* H. L. ALDER, H. M. GEHMAN, EVERETT PITCHER, all *ex officio.*

NOMINATING COMMITTEE FOR 1967

R. H. BING, *Chairman;* P. T. BATEMAN, O. G. HARROLD.

EDITORIAL BOARDS OF THE ASSOCIATION

AMERICAN MATHEMATICAL MONTHLY (all terms expire December 31, 1971).

Editor: R. A. ROSENBAUM

Associate Editors: JOSHUA BARLAZ, J. A. BROWN, LEONARD CARLITZ, HASKELL COHEN, HOWARD EVES, HARLEY FLANDERS, RAOUL HAILPERN, M. S. KLAMKIN, R. C. LYNDON, A. P. MATTUCK, K. O. MAY, J. R. MAYOR, G. N. RANEY, GIAN-CARLO ROTA, E. P. STARKE, J. G. WENDEL, ALBERT WILANSKY.

MATHEMATICS MAGAZINE (all terms expire December 31, 1968).

Editor: ROY DUBISCH

Associate Editors: R. W. BAGLEY, D. B. DEKKER, RAOUL HAILPERN, R. E. HORTON, J. H. JORDAN, C. T. LONG, SAM PERLIS, RUTH B. RASMUSEN, H. E. REINHARDT, R. W. RITCHIE, J. M. SACHS, HANS SAGAN, C. T. SANDERS, D. E. THORO, L. M. WEINER.

REPRESENTATIVES OF THE ASSOCIATION

On the AAAS Cooperative Committee on the Teaching of Mathematics and Science:
K. O. MAY (1966–68)

On the American Council on Education:
H. L. ALDER, *ex officio*, E. E. MOISE, *ex officio*

On the Conference Board of the Mathematical Sciences:
H. L. ALDER, *ex officio*, E. E. MOISE, *ex officio.*

On the Council of the American Association for the Advancement of Science:
R. D. ANDERSON (1965–67), M. M. DAY (1966–68)
On the Governing Council of Mu Alpha Theta:
G. B. PRICE (1967–69)
On the National Council for Accreditation of Teacher Education:
G. S. YOUNG (November 1966–October 1968)
On the National Research Council:
R. H. BING (July 1, 1965–June 30, 1968)
On the U.S. Commission on Mathematical Instruction:
R. P. DILWORTH (July 1, 1966–June 30, 1970), LEONARD GILLMAN (July 1, 1965–June 30, 1969).

APRIL MEETING OF THE MINNESOTA SECTION

The Spring meeting of the Minnesota Section of the MAA was held at Macalester College, St. Paul, Minnesota on April 30, 1966. There were 108 persons in attendance including 87 members of the Association. Professor E. J. Camp of Macalester College presided over the morning sessions; Professor F. L. Wolf of Carleton College presided over the afternoon sessions. The sessions were held in the new Olin Hall of Science.

At the business meeting the following officers were elected: Chairman, Dale Varberg, Hamline University; Secretary-Treasurer, Rev. Walbert Kalinowski; Executive Committee, Frank Wolf, Carleton College; Ernest Stennes, St. Cloud State College; Sylvan Burgstahler, University of Minnesota at Duluth; E. J. Camp, Macalester College. It was decided to pay membership fees to the MAA for those students who did well in the Putnam Examination. A report on the results of the High School Examination was also given.

The program of the sessions was as follows:

1. *Some reminiscences of Raymond Clair Archibald*, by Sister M. Thomas à Kempis, College of St. Teresa.

2. *Convergence of series obtained by iteration*, by G. U. Brauer, University of Minnesota.

3. *Newton's method for transformations*, by A. W. Roberts, Macalester College.

4. *Perturbation of the integral operator with separable kernel*, by H. I. Freedman, University of Minnesota.

5. *An application of finite fields to a scheduling problem*, by Bert Fristedt, University of Minnesota.

6. *An explicit formula for* e^{At}, by R. B. Kirchner, Carleton College.

7. *Group theory and spin state quantum mechanics*, by J. W. Mentele, South Dakota State University.

8. *Composition and decomposition of polynomials*, by James Sitton and Peter Crescenzo, University of Minnesota.

9. *An uncountable collection of mutually singular Cantor functions*, by Edward Emerson, University of Minnesota.

10. *Stability in autonomous systems of differential equations*, by Lynn D. Maruska, Macalester College.

11. *Disconjugacy for a linear differential operator*, by R. M. Mathsen, Concordia College.

12. *Non-linear phenomena*, by W. S. Loud, University of Minnesota (by invitation).

13. *On a circle theorem of Descartes*, by Daniel Pedoe, University of Minnesota (by invitation).

14. *Panel discussion: The CUPM Report—a general curriculum in mathematics for colleges*, by Murray Braden, Macalester College (moderator) and H. L. Turrittin, University of Minnesota; H. M. Anderson, Gustavus Adolphus College; W. J. Thomsen, Moorhead State College; J. E. Lange, St. John's University (panelists).

W. C. KALINOWSKI, *Secretary-Treasurer*

NOVEMBER MEETING OF THE NEW JERSEY SECTION

The eleventh annual meeting of the New Jersey Section of the MAA was held at Rutgers—The State University, on November 12, 1966. Professor Joshua Barlaz, Chairman of the Section, presided at the morning session and F. A. Brooks, Jr., Senior Member of the Executive Committee, presided at the afternoon session. Seventy-seven persons attended the meeting including sixty-four members of MAA.

At the business meeting Vice-Provost and Dean A. E. Meder, Jr., of Rutgers—The State University, was elected Chairman, and Professor H. F. Trotter of Princeton University was elected Member at Large of the Executive Committee ('69). Reports were presented by F. A. Varrichio, Secretary-Treasurer, and F. A. Brooks, Jr.—High School Contest Committee.

The morning session was as follows:

1. *General Curriculum for Mathematics in Colleges*, by A. W. Tucker, Princeton University (by invitation).
Analysis and discussions of 1965 Report by CUPM.

2. *What is a Point?* by L. F. McAuley, Rutgers—The State University (by invitation).

The afternoon session was as follows:

1. *Moonlighting in Moscow*, by R. M. Cohn, C. C. Sims, and E. J. Taft, Rutgers—The State University (by invitation).
Comments and sidelights of International Congress of Mathematicians in Russia, August 1966.

2. Film: *The Kakeya Problem*, A. S. Besicovitch.

F. A. VARRICHIO, *Secretary-Treasurer*

MAA PUBLICATIONS

A new volume in the series of MAA Studies will be published during the summer of 1967: MAA Studies Volume 4, Studies in Global Geometry and Analysis, S. S. Chern, editor. It contains papers by Marston Morse, S. S. Chern, Harley Flanders, S. Kobayashi, Lamberto Cesari, L. A. Santalo.

Each individual member of MAA may purchase one copy of this book at the reduced price of $3.00. Orders accompanied by payment should be sent to the Buffalo office. Additional copies and copies for nonmembers may be purchased at $6.00 from Prentice-Hall, Inc., Englewood Cliffs, New Jersey 07631.

Effective July 1, 1967, the price to members for all Carus Monographs and MAA Studies Volumes 1, 2, and 3 will be increased to $3.00 per copy. The non-member price has been increased to $6.00. Orders from members received by the Buffalo office before July 1 will be filled at the current rate of $2.00 each.

An announcement listing all MAA publications with current and prospective prices is being mailed to all MAA members this spring. Additional copies of the announcement may be obtained from the Buffalo office.

REPORT OF THE TREASURER FOR THE YEAR 1966

Following is a summary of the report of Professor H. M. Gehman as Treasurer of the Association for the year 1966. The report has been approved by the Finance Committee and accepted by vote of the Board of Governors. Any MAA member who wishes a copy of the consolidated report of the Treasurer may obtain one by writing to the Buffalo office of the Association.

A member who wishes to remain anonymous has given MAA securities valued at about $5,000. This gift has been added to the so-called Anonymous Fund.

The general decrease in market values of securities during 1966 has resulted in decreases in nearly all of the special funds of the Association. Also the funds devoted to publications have been subject to fluctuations depending upon payments for printing.

During 1966 final agreement was reached with NSF about indirect costs for 1965 and preceding years. Appropriate adjustments have been made in the MAA financial records.

For several years the Current Fund has had a small deficit. These deficits and expected increases in expenditures during 1967 and 1968 have resulted in an increase in dues effective in 1968.

	January 1, 1966	*December 31, 1966*

CALENDAR OF FUTURE MEETINGS

Forty-eighth Summer Meeting, University of Toronto, Toronto, Ontario, Canada, August 28–30, 1967.

Fifty-first Annual Meeting, San Francisco, California, January 25–27, 1968.

The following is a list of the Sections of the Association with dates of future meetings so far as they have been reported to the Associate Secretary.

ALLEGHENY MOUNTAIN, West Virginia University, Morgantown, May 6, 1967.

ILLINOIS, University of Illinois, Urbana, May 12–13, 1967.

INDIANA, Wabash College, Crawfordsville, May 13, 1967.

IOWA

KANSAS

KENTUCKY

LOUISIANA-MISSISSIPPI

MARYLAND-DISTRICT OF COLUMBIA-VIRGINIA

METROPOLITAN NEW YORK

MICHIGAN

MINNESOTA, St. John's University, Collegeville, May 6, 1967.

MISSOURI

NEBRASKA, University of South Dakota, Vermillion, May 6, 1967.

NEW JERSEY

NORTHEASTERN, Mt. Allison University, Sackville, New Brunswick, June 23–24, 1967.

NORTHERN CALIFORNIA

OHIO

OKLAHOMA-ARKANSAS

PACIFIC NORTHWEST, University of Montana, Missoula, June 16–17, 1967.

PHILADELPHIA, University of Delaware, Newark, November 18, 1967.

ROCKY MOUNTAIN, Western State College of Colorado, Gunnison, May 12–13, 1967.

SOUTHEASTERN

SOUTHERN CALIFORNIA

SOUTHWESTERN

TEXAS

UPPER NEW YORK STATE, State University College, Plattsburgh, May 20, 1967.

WISCONSIN, St. Norbert College, DePere, May 6, 1967.

FUTURE MEETINGS OF OTHER ORGANIZATIONS

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE, New York, N.Y. December 26–31, 1967.

AMERICAN MATHEMATICAL SOCIETY, Toronto, Ontario, Canada, August 29–September 1, 1967.

AMERICAN SOCIETY FOR ENGINEERING EDUCATION, Michigan State University, June 19–22, 1967.

ASSOCIATION FOR COMPUTING MACHINERY, Sheraton-Park, Washington, D. C., August 29–31, 1967.

ASSOCIATION FOR SYMBOLIC LOGIC, Chicago, May 4–5, 1967.

CENTRAL ASSOCIATION OF SCIENCE AND MATHEMATICS TEACHERS, Chicago, November 23–25, 1967.

NATIONAL COUNCIL OF TEACHERS OF MATHEMATICS, McGill University, Montreal, August 21–24, 1967.

OPERATIONS RESEARCH SOCIETY OF AMERICA, New York Hilton Hotel, May 31–June 2, 1967.

PI MU EPSILON, Toronto, Ontario, Canada, August 29–30, 1967.

SOCIETY FOR INDUSTRIAL AND APPLIED MATHEMATICS, Shoreham Hotel, Washington, D. C., June 12–15, 1967 (Symposiums on applied probability and fluid dynamics).

Outstanding Texts from HRW

CALCULUS AND ANALYTIC GEOMETRY, Second Edition

ABRAHAM SCHWARTZ, *The City College of the City University of New York*

As in the first edition, this text for the introductory calculus course begins with chapters on the differential and integral calculus which rest on an intuitive basis rather than an abstract one. In this second edition, the definition of "function" at the beginning of the book has been written in more precise terms, and the first intuitive definition for integrals in Chapter Two has been improved. A completely new feature is the addition of a chapter on differential equations.

March 1967 1024 pp. $12.50

A FIRST COURSE IN ABSTRACT ALGEBRA

HIRAM PALEY and PAUL M. WEICHSEL, *both of the University of Illinois*

1966 334 pp. $8.95

LINEAR EQUATIONS OF MATHEMATICAL PHYSICS

S. G. MIKHLIN, *Leningrad State University*

Translated by Scripta Technica, Inc.; translation edited by HARRY HOCHSTADT, Polytechnic Institute of Brooklyn

January 1967 336 pp. $10.95

MATHEMATICS OF AUTOMATIC CONTROL

TOSHIE TAKAHASHI, *Tokyo, Japan*

Translated by Scripta Technica, Inc.; translation edited by GEORGE M. KRANC, The City College of the City University of New York

1966 456 pp. $14.50

NEW, SPRING, 1967

INTRODUCTORY MATHEMATICS

By SEYMOUR HAYDEN, *Professor and Chairman, Department of Mathematics, Clark University.*

500 pp. of text plus answers and solutions to selected exercises in each chapter. All other answers available in a separate manual. Tentative list price $9.00.

Designed not only for the first course in college mathematics but also for the mathematics education program.

Some Special Features:

1. Modern mathematical concepts are developed; their applicability to topics from the elementary curriculum exposed.
2. The general discussion of functions, relations, inverse functions, inverse relations, and branch functions is made use of in the chapters on polynomial, exponential and logarithmic, and trigonometric functions.
3. Historical comments and discussions of unsolved problems are introduced to bring out the living nature of mathematics.
4. A thorough treatment of mathematical induction and recursive definitions is presented.
5. Approximately half of the text is devoted to illustrative material and exercises.

In Canada: 25 Hollinger Road, Toronto 16, Ontario

NEW FROM PRENTICE-HALL

MODERN ELEMENTARY STATISTICS, 3RD ED., 1967

by John E. Freund, *Arizona State University*

This widely used text emphasizes the meaning of statistics rather than the manipulation of formulas. It explains the basic principles and applications of statistics in a clear, informal, and non-technical manner. The new Third Edition increases emphasis on statistical inference, and offers a completely new and modern treatment of probability and others. *January 1967, 432 pp., $9.25*

INTEGRATED ALGEBRA AND TRIGONOMETRY (With Analytic Geometry) 2nd Ed., 1967

by Robert C. Fisher, *Ohio State University* & Allen D. Ziebur, *State University of New York at Binghamton*

This thorough revision of the first edition —one of the most widely used texts in the field—offers accurate, readable, and complete coverage of pre-calculus mathematics. With a unifying theme of the concept of a function and its graph, the book encompasses topics in algebra, trigonometry, and analytic geometry which are a prerequisite to further study in calculus. *March 1967, 480 pages, $8.95*

LINEAR TRANSFORMATIONS AND MATRICES

by F. A. Ficken, *New York University*

Presents the basic theory of finite-dimensional real and complex spaces; designed for students taking a first "conceptual" course.

". . . I would unhesitatingly recommend it for prospective applied mathematicians." . . . from our files. *January 1967, 398 pp., $10.50*

INTRODUCTION TO CONTEMPORARY ALGEBRA

by Marvin L. Tomber, *Michigan State University*

The underlying theme of this new book is the rational development of algebra as a fundamental human discipline. An informal development of algebra from its axioms, this book has been prepared to meet the requirements of modern algebra courses as outlined by the Committee on the Undergraduate Program in Mathematics. *January 1967, 429 pp., $7.95*

APPLIED DIFFERENTIAL EQUATIONS, 2nd Ed., 1967

by Murray R. Spiegel, *Rensselaer Polytechnic Institute*

"Spiegel's book is outstanding for its attempts at unified treatments of many topics, for its good selection of exercises, and for its clarity in presenting techniques for solution of differential equations. . . . This book remains what it always was: one of the best of its type . . ." pre-publication review. *February 1967, 384 pp., $8.50*

THE ALLYN AND BACON SERIES IN ADVANCED MATHEMATICS

"The Allyn and Bacon Series in Advanced Mathematics is designed to provide expositions of the basic areas of mathematics at the upper undergraduate and beginning graduate levels. It is at this point that the student's acquaintance with modern mathematics really begins. A good text will, of course, supply the usual indispensable features: a high level of exposition, plenty of exercises ranging from routine ones to ingenious challenges, and stimulating glimpses of where the subject goes when you penetrate deeper. A superb text does even more: it lets the student share the excitement that accompanied the great discoveries of the last century. It is to the development of superb texts that the Series is dedicated."

DICKENSON
PUBLISHING COMPANY, INC.
BELMONT, CALIFORNIA 94002

Important new books from McGraw-Hill

ESSENTIAL BUSINESS MATHEMATICS, Fifth Edition.
By L. R. SNYDER, City College of San Francisco.

Thoroughly revised, this excellent undergraduate text increases the student's knowledge and skill in computing practical financial problems. All topics, such as social security, income tax withholding, stock and bond execution prices and transfer taxes, fire insurance, etc. are completely up-to-date. **Spring.**

FUNDAMENTALS OF COLLEGE ALGEBRA.
By CARL B. ALLENDOERFER, University of Washington; and CLETUS O. OAKLEY, Emeritus, Haverford College.

This modern treatment for the regular course offers much more than just "college algebra": it includes sets and logic; an unusually careful discussion of mathematical induction; introduction to matrix and vector algebra; stress on solution of inequalities in one and two variables; and unusually large sets of problems. **446 pp., $7.50.**

COLLEGE ALGEBRA, Fifth Edition.
By PAUL K. REES, Louisiana State University; and FRED W. SPARKS, Professor Emeritus, Texas Technological College.

The new edition of this highly teachable text features axiomatic rigor using modern terminology and the theory of sets rather than the traditional, relatively looser approach. It presents the essentials for further progress in clear, concise style. Graded problems, gradually increasing in difficulty, are provided a normal lesson apart. **Off Press.**

FUNDAMENTAL MATHEMATICS, Third Edition.
By THOMAS L. WADE and HOWARD E. TAYLOR, both of Florida State University.

In the third edition of this well-established introductory college mathematics text, the topics proceed from a basis in sets and are discussed in modern terminology. Thoroughly revised, the book increases emphasis on structure or pattern in fundamental mathematics and makes more use of the concepts of set. **Off Press.**

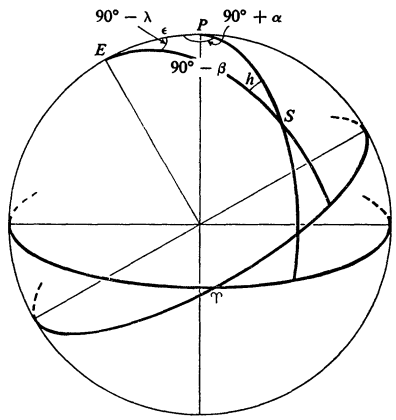
LIMITS AND CONTINUITY.
By TEDDY C. J. LEAVITT, State University College, Plattsburgh, N. Y.

This helpful supplement leads students from intuitive ideas about the difficult concepts of limits and continuity to the fairly rigorous definitions and manipulations that are a part of the calculus course. Algebra, topology, and modern analysis are combined in a new way to simplify the concept of continuity and limits. **Spring.**

CALCULUS IN THE FIRST THREE DIMENSIONS.
By SHERMAN R. STEIN, University of California, Davis.

This introductory calculus text for a one-year course stresses fundamentals and offers a broad range of applications in economics, the physical sciences, etc. It deals with such subjects as the definitive integral, the derivative, and the law of means. It also covers special topics such as higher derivatives, maxima, series and vectors. **640 pp., $9.95.**

MODERN COLLEGE ALGEBRA.
By FLOYD LAMAR BLANTON and JAMES EARL PERRY, both of Abraham Baldwin College of The University System of Georgia.



This modern approach preserves the traditional basic material of college algebra and includes special, non-sequential topics to challenge adventurous students. It features the axiomatic presentation of the basic ideas of algebra within the framework of modern set terminology and elementary rules of logic. **288 pp., $6.95.**

Examination copies available on request.

New Books From Freeman

Principles of Astrometry

With Special Emphasis
on Long-Focus Photographic Astrometry

PETER VAN DE KAMP,
Sproul Observatory, Swarthmore College

Here is the first general introduction to the theory, technique, reduction methods, and results of astrometry, particularly of long-focus photographic astrometry. *1967, 240 pages, illustrated, $6.50*

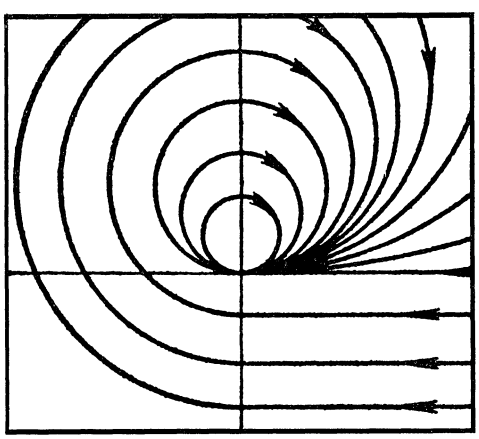
Abstract Theory of Groups

O. U. SCHMIDT, Translated from the Russian by Fred Holling, Portland State College, and J. B. Roberts, Reed College. Edited by J. B. Roberts

This book is an English translation of one of the classic works in the literature of group theory. *1967, 174 pages, $5.00*

$$\sum_R \chi_\rho(SR^{-1})\chi_\rho(R) = \frac{h}{f_\rho}\chi_\rho(S) .$$

$$\sum_R \chi_\rho(R^{-1})\chi_\rho(R) = h .$$



$$\sum_R a^{SR^{-1}}_{\beta\alpha}\, a^{TR}_{\alpha\beta} = \frac{h}{f} a^{S}_{\beta\beta}\, a^{T}_{\alpha\alpha} .$$

Problems in Differential Equations

Second Edition

J. L. BRENNER, Stanford Research Institute. Adapted from the Russian book by A. F. FILIPPOV

Designed as an adjunct text for elementary and intermediate courses in differential equations, this book contains more than 900 problems, with answers. The second edition contains an expanded section on linear differential equations with constant coefficients, with fuller explanations and complete theoretical treatment, and a short section on Laplace transform methods for solving linear differential equations with constant coefficients. *1966, 172 pages, illustrated, paperbound, $2.50*

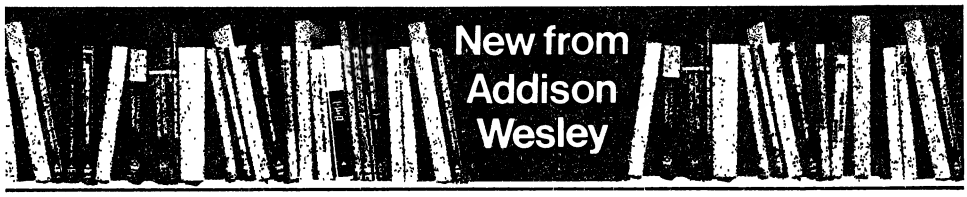
Calculus and Analytic Geometry



JACK R. BRITTON, University of West Florida
R. BEN KRIEGH, University of Colorado
LEON W. RUTLAND, Virginia Polytechnic Institute

This new book is a condensation and rearrangement of the authors' two-volume work, *University Mathematics* I, II. It is so organized as to enable the student to reach the calculus within the first few weeks of the course.

The authors have followed many of the recent recommendations of national groups concerned with the undergraduate program in mathematics. They provide a sensible continuation of the modern approach to mathematics that is now introduced in most high schools, with more emphasis than in the past placed on an understanding of fundamental concepts. *1966, 1069 pages, 386 illustrations, $12.50.*

Examination copies available.

Warner House, 48 Upper Thames Street, London, E.C. 4

CALCULUS FOR COLLEGE STUDENTS

By MURRAY H. PROTTER and CHARLES B. MORREY, JR., *University of California.*

This is a calculus text for students who have had analytic geometry in high school or in a separate college course. Except for the omission of analytic geometry, and the chapter on linear algebra, the content of this text is virtually the same as the authors' *College Calculus with Analytic Geometry*. Like their former book, this text is designed to be equally attractive to students of both science and engineering and pure mathematics.

730 pp. 417 illus. $10.75

MATRICES AND LINEAR TRANSFORMATIONS

By CHARLES G. CULLEN, *University of Pittsburgh.*

The first five chapters of this book on linear algebra comprise a one-term text for science, engineering and mathematics students which covers those topics most frequently encountered in applications. Only a first course in calculus and analytic geometry is required. Aimed at the sophomore-junior level, the text approaches the subject from the matrix theory point of view rather than from the more abstract approach using linear transformations.

272 pp. $8.95

INTRODUCTION TO LINEAR ANALYSIS

By DONALD L. KREIDER, *Dartmouth College,* ROBERT G. KULLER, *Wayne State University,* DONALD R. OSTBERG, *State University of New York at Buffalo,* and FRED W. PERKINS, *Dartmouth College.*

This book, which assumes a background in calculus, is designed to serve as an introductory text in applied analysis for students of science and engineering. It covers much of the traditional material, however it also treats topics which are of importance in present day mathematics. The concept of linearity is emphasized and used as a unifying thread which ties together the treatment of topics often presented in an isolated manner.

773pp. 177 illus. $12.50

INTRODUCTION TO ANALYTIC FUNCTIONS

By WILFRED KAPLAN, *University of Michigan.*

The present book is designed to provide an elementary introduction to functions of complex variables and their applications, for senior and graduate students of science and engineering. The text is based directly on Chapter Nine of the author's *Advanced Calculus,* and also includes a completely new chapter on analytic functions of several complex variables; coverage rarely made accessible at this level.

212 pp. 78 illus. $7.95

SET THEORY AND LOGIC

By ABRAHAM FRAENKEL, *The Hebrew University of Jerusalem.*

In the Adiwes International Series.

Although the reader of this new monograph translated from the German must be able to deal adequately with abstract generalizations, no formal mathematical background is required for its study. Reviewers of the German edition have praised its high scientific level and have suggested that it is essential reading for all in-training teachers and highly recommended for students taking introductory courses in mathematics. The author uses a historical approach to develop the fundamental concepts of abstract set theory. The concepts, as well as the proofs, are then subjected to detailed analysis.

102 pp. $7.50

INTRODUCTION TO MODERN ABSTRACT ALGEBRA

By DAVID M. BURTON, *University of New Hampshire.*

This book is designed for an undergraduate course in abstract algebra. While all of the important topics are covered in some detail, the emphasis is on ring theory. A prerequisite required for an understanding of this text is the usual material covered in an introductory calculus course.

THE SIGN OF EXCELLENCE

Outstanding textbooks

BASIC MATHEMATICS FOR ELEMENTARY TEACHERS

Ward D. Bouwsma and **Clyde G. Corle** —both The Pennsylvania State University; and **Davis F. Clemson, Jr.**, State College High School, Pennsylvania

New—for content courses in mathematics as given to prospective and in-service elementary school teachers. Book's unifying theme is the repeated extension of the universal set of numbers, leading from the natural numbers to the integers, then to the rationals, and then to the reals. Stress is laid upon preserving basic laws of arithmetic with each extension and upon understanding standard algorithms. The arrangement of topics is flexible, allowing individual instructors to select and arrange the order in which they are given. Book reflects the recommendations of the Committee of the Undergraduate Program in Mathematics of the Mathematical Association of America. *1967. 342 pp.* *$7.00*

FUNDAMENTALS OF NUMERICAL ANALYSIS

Augustus H. Fox, Union College

A lucid introduction to the basic methods involved in the numerical solutions of systems of algebraic equations, and ordinary and partial differential equations. The book fills the gap between the usual study of calculus and differential equations and the special techniques of modern technology by numerical analysis using large computer systems. Problems avoid the use of anything more extensive than a desk calculator. *1963. 147 pp.* *$6.00*

MATHEMATICAL METHODS IN ENGINEERING AND PHYSICS

Special Functions and Boundary-Value Problems

David E. Johnson and **Johnny R. Johnson**—both Louisiana State University

This versatile textbook is designed to acquaint the student with the characteristics of the more important special functions used to solve partial differential equations in engineering and physics. Topics generally considered to be on an advanced level are presented here in a form suitable for students of less extensive backgrounds. Applications, most of which involve boundary-value problems, are discussed as they arise in the examination of the functions themselves. While there is a brief discussion of transform methods, primary emphasis is on the separation-of-variables method. Includes a comprehensive bibliography. Instructor's Supplement available. *". . . a useful contribution to the mathematical literature."*—**American Scientist.** *1965. 273 pp.* *$9.50*

STATISTICAL ANALYSIS

Samuel B. Richmond, Columbia University

In this modern treatment of the subject, statistics and statistical analyses are considered as major tools in the decision-making process. Although no mathematical preparation beyond secondary school algebra is required, theoretical correctness has not been compromised. Recently developed ideas involving Bayes' theorem and subjective problems are discussed. Extensive illustrative problems. Instructor's Supplement available. *2nd Ed., 1964. 633 pp., illus.* *$8.50*

LINEAR ALGEBRA

By SERGE LANG, *Columbia University.*

This book is meant as a text for a one-year course in algebra at the undergraduate level, during the sophomore or junior year. It starts with the basic notion of vectors in real Euclidean space, which sets the pattern for much that follows. Examples and special cases are worked out in abundance, and abstractions are developed slowly.

294 pp. 20 illus. $8.95

AN INTRODUCTION TO VECTOR FUNCTIONS

By JAMES A. HUMMEL, *University of Maryland.*

At the sophomore-junior level, this book offers material for a first course after calculus. It provides the mathematics needed for applications, and is intended mainly for engineers and physicists. Coverage includes vector spaces, linear transformations, determinants, matrices, functions of several variables, differentials, integration, an introduction to curves and surfaces, and vector analysis.

In Press

ALGEBRAIC STRUCTURES

By SERGE LANG, *Columbia University.*

This book is designed for use as a text in modern algebra. Together with the author's *Linear Algebra,* it constitutes a curriculum for an algebra program addressed to undergraduates. Although the present book is self-contained logically, it is perhaps advisable to take the linear algebra course *before* being introduced to the more abstract notions of groups, rings, and fields, and the systematic development of their basic abstract properties.

173 pp. $6.95

A FIRST COURSE IN ABSTRACT ALGEBRA

By JOHN B. FRALEIGH, *University of Rhode Island.*

Aimed at the average mathematics major, this text has the primary objective of achieving maximum depth and comprehension in a first course. The book is designed to teach material of a level previously available only in texts intended for honors students. The coverage constitutes a basic introduction to modern algebra, exclusive of linear algebra.

In Press

ELEMENTARY TOPOLOGY

By MICHAEL C. GEMIGNANI, *State University of New York, Buffalo.*

This text is written at the appropriate level for an undergraduate course in topology, although under certain circumstances, it might also be used for a beginning graduate course. If the student has completed at least three semesters of a calculus and analytic geometry sequence, he should have sufficient background to understand this book.

In Press

NUMBER SYSTEMS OF ANALYSIS

By G. CUTHBERT WEBBER, *University of Delaware.*

The primary objective of this text is to provide a development of the real number system coverable in one semester. The book also includes an extension to the complex numbers. A modification of the Peano postulates is used as the starting point, and Cauchy sequences for the transition from rationals to reals. The material on Cauchy sequences is designed to lend itself to a discussion of the distinction between proof construction and proof presentation.

213 pp. 4 illus. $7.95

ELEMENTARY CALCULUS FROM AN ADVANCED VIEWPOINT

By GEORGE B. THOMAS, JR., *Massachusetts Institute of Technology,* JOHN K. MOULTON, *Brookline High School, Massachusetts,* and MARTHA ZELINKA, *Weston High School, Massachusetts.*

This text grew out of a series of lectures given to high school teachers of advanced placement calculus, and is intended to provide a deeper understanding of elementary calculus. The main purpose of the book is to show the structure of elementary calculus and its analytical foundations. Theoretical ideas are carefully explained and motivated, and applied to particular problems.

ADVERTISING CORRESPONDENCE should be addressed to RAOUL HAILPERN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

NOTICE OF CHANGE OF ADDRESS by members of the Association as well as correspondence regarding subscriptions to the MONTHLY should be sent to the Executive Director, H. M. GEHMAN, Mathematical Association of America, SUNY at Buffalo, Buffalo, N. Y. 14214.

NOTICE TO AUTHORS

The MONTHLY welcomes papers presenting valid mathematics, of rather general interest, at a level intelligible to persons with two years of full-time graduate study. Some novelty of content, viewpoint, or arrangement is essential. Expository articles are particularly desired. State the context and the principal aim of the paper early. Address yourself quite explicitly to the reader described above, communicating your ideas to him clearly and attractively.

The title should be brief and meaningful. Since the title will be quoted and reproduced by laymen, it should contain no symbols unfamiliar to laymen.

Articles should be typewritten, double-spaced, on $8\frac{1}{2}\times 11''$ paper of very good quality. Submit the original (and a duplicate if convenient) keeping a complete copy for yourself. To avoid loss and delay notify us of any change of address.

The typescript should be prepared with extreme care. Misprints are highly obnoxious; so are dangling participles. Put name and address between title and text. Put references at the end with bracketed citations in the text. Avoid footnotes; instead, use clearly designated remarks in the text. Put acknowledgments at the very end, just before the bibliography. Be generous with spacing and displays. *Keep notation simple.* For a matrix the notation $[a_{jk}]$ is recommended, with $\det [a_{jk}]$ or $|a_{jk}|$ for the determinant. On doubtful questions regarding format or notation, observe practices in current issues of the MONTHLY or consult the applicable sections of the "Author's Manual" of the American Mathematical Society.

Annual dues for members of the Association (including a subscription to the American Mathematical Monthly) are \$6.00 (\$8.00 in 1968). For nonmembers the subscription price is \$10.00.

PUBLISHED BY THE ASSOCIATION at Menasha, Wisconsin, and Buffalo, N. Y.
during the months of January, February, March, April, May, June–July, August–September, October, November, December.

Second-class postage paid at Menasha, Wisconsin. Acceptance for mailing at special rate of postage provided for in the Act of February 28, 1925, embodied in Paragraph 4, Section 538, P. L. and R., authorized April 1, 1926.

ON THE FUNDAMENTAL THEOREM OF ALGEBRA

HANS ZASSENHAUS, Ohio State University

Introduction. In the year 1799 C. F. Gauss [4] gave the first formal proof of the theorem that every nonconstant polynomial with real coefficients can be factored into a product of linear factors and quadratic factors. A constructive proof based on arguments of a purely algebraic nature and on assumptions about the real number field that were stated in purely algebraic terms (though the proof of these assumptions would require analytic methods) was first given by O. Perron [6]. In this paper Perron's method is further developed towards an algorithmic routine for solving algebraic equations with complex coefficients.

1. Really closed fields. The real number field has the following properties:

1.1. The negative of a nonsquare is a square.

1.2. The sum of squares is zero only if each summand is zero.

1.3. An algebraic equation of odd degree has a real solution.

The first two properties derive from the existence of an algebraic ordering of the real number field and a square root of every positive real number.

The last property follows from an application of the intermediate-value theorem of analysis to a polynomial: $f(x)=x^n+a_1x^{n-1}+\cdots+a_n$ of odd degree n with real coefficients, in view of the inequalities:

$$1.4 \qquad f\left(1+\sum_{i=1}^{n}|a_i|\right)>0>f\left(-\left(1+\sum_{i=1}^{n}|a_i|\right)\right).$$

Fields with the properties 1.1, 1.2, 1.3 are said to be *really closed.* E.g. the real number field is really closed. For a really closed field F an algebraic ordering is given by the rule:

1.5 The element a of F is greater than the element b of F if and only if the difference element $a-b$ is a nonzero square element of F. This implies the positivity concept:

1.6 An element of F is positive if and only if it is a nonzero square element of F.

In order to deduce the ordering properties of F from 1.5 we have to verify the positivity rules:

1.7 The negative of any nonpositive nonzero element is positive.

1.8 The sum and product of two positive elements are positive.

Indeed, if a is non positive and nonzero, then a is a non square of F. It follows from 1.1 that $-a$ is a square element of F so that $-a$ is positive.

If a and b are positive elements of F then the equations

$$a=\xi^2, \qquad b=\eta^2$$

are solvable by non zero elements ξ, η of F. From 1.2 it follows that $a+b$ does not vanish. If there would hold an equation: $-(a+b)=\zeta^2$ in F then

$$\xi^2+\eta^2+\zeta^2=0$$

would hold contrary to 1.2.

Thus $a+b$ is a square element of F so that the sum of two positive elements of F always is positive. Since,

$$ab = \xi^2\eta^2 = (\xi\eta)^2 \neq 0$$

the product of two positive elements is positive.

Clearly, for any really closed field only one positivity concept exists.

2. Ordered division rings. (See [1], [2], [3], [5], [7]). For a unital ring D with positivity concept satisfying 1.7, 1.8 we define an algebraic ordering by declaring the relation

$$a > b \text{ (or: } b < a)$$

to mean that the difference of the elements a, b of D is positive.

This definition implies the rules customarily demanded of an algebraic ordering relation:

2.1 (trichotomy). For any two elements a, b of R, there holds one and only one of the three relations:

$$a > b, \qquad a = b, \qquad b > a.$$

2.2 (transitivity). If $a>b$, $b>c$ then $a>c$.

2.3 If $a>b$, $c>d$ then $a+c>b+d$ and $ac+bd>ad+bc$.

Conversely, if $a>$relation is defined in D which satisfies 2.1, 2.3 then the relation $a>0$ defines a positivity concept satisfying 1.7 and 1.8, from which the $>$relation can be derived as was done above.

The derived relation:

$$a \geqq b \text{ (or: } b \leqq a)$$

meaning that either a is greater than b or a is equal to b (or: not $a<b$) and the functions:

$$\operatorname{sign} a = \begin{cases} 1 & \text{if } a > 0 \\ 0 & \text{if } a = 0 \\ -1 & \text{if } a < 0 \end{cases}$$

$$|a| = a \cdot \operatorname{sign} a = (\operatorname{sign} a) \cdot a$$

satisfy the basic rules:

$$a \geqq a, \qquad a \geqq b \text{ and } b \geqq a \Rightarrow a = b, \qquad a \geqq b \text{ and } b \geqq c \Rightarrow a \geqq c,$$

$$a \geqq b \text{ and } c \geqq d \Rightarrow a + c \geqq b + d, \qquad ab + cd \geqq ad + cb$$

$$\operatorname{sign}(ab) = \operatorname{sign} a \cdot \operatorname{sign} b$$

$$|a| \cdot \operatorname{sign} a = (\operatorname{sign} a) \cdot |a| = a$$

$$|a| = |-a| \geqq 0, \qquad |a| = 0 \Leftrightarrow a = 0,$$

$$|a+b| \leqq |a| + |b|, \qquad |a-b| \geqq ||a| - |b||, \qquad |ab| = |a| \cdot |b|.$$

The positive elements of an ordered division ring D form a half-ring H (according to [8], p. 95, a halfring is a nonempty subset of a ring that is closed under addition and multiplication,) with the following properties:

2.4. The halfring H contains the square of every non zero element of the subdivision ring D_H generated by H.

2.5. The halfring H is a maximal subhalfring of D not containing the zero element of D.

Conversely, every halfring H of D satisfying 2.4 and 2.5 is associated with a positivity concept of D_H satisfying 1.7, 1.8.

Indeed, for any two non zero elements u, v of D we have the identity:

$$2.6 \qquad uvu^{-1}v^{-1} = (uv)^2(v^{-1}u^{-1}v)^2(v^{-1})^2$$

so that

$$2.7 \qquad uvu^{-1}v^{-1} \in H \quad \text{if } 0 \neq u \in D_H,\ 0 \neq v \in D_H.$$

Thus $uh = h(h^{-1}u\ hu^{-1})u \in Hu$ if $0 \neq u \in D_H$, $h \in H$; hence $hu \in uH$, $uH \subseteq Hu$. Similarly $Hu \subseteq uH$; hence $uH = Hu (u \in D_H)$.

For h of H we have

$$H = h^{-1}hH \subseteq h^{-1}H, \qquad h^{-1} = h^{-1}1^2 \in h^{-1}H,$$
$$h^{-1}H + h^{-1}H \subseteq h^{-1}H,$$
$$h^{-1}Hh^{-1}H = h^{-1}(Hh^{-1})H = h^{-1}h^{-1}HH \subseteq H \subseteq h^{-1}H,$$

hence $h^{-1}H$ is a halfring of D_H containing H, but not zero. Since $h^{-1}H$ contains every non zero square element of $D_H = D_{h^{-1}H}$ it follows from the maximal property of H that $h^{-1}H = H$, hence $h^{-1} \in H$.

If the non zero element c of D_H is not contained in H then $-c$ belongs to H. Indeed,

$$c = c \cdot 1^2 \in cH \subseteq \hat{H} = H \cup cH \cup (H + cH)$$
$$(H + cH) + (H + cH) \subseteq H + cH$$
$$HcH = cHH \subseteq cH,$$
$$cHcH = c(Hc)H = c(cH)H = c^2HH \subseteq H$$
$$(H + cH)(H + cH) \subseteq H + cH.$$

Hence, $\hat{H}$ is a halfring of D_H properly containing H, so $\hat{H}$ contains zero because of the maximal property of H.

There are elements h_1, h_2 of H for which $h_1 + ch_2 = 0$. Hence,

$$-c = h_1h_2^{-1} \in HH = H.$$

THEOREM 1. *A division ring D can be algebraically ordered if and only if the sum of finitely many finite products of square elements is zero only if all summands are zero.* (What happens if one makes the weaker assumption that the sum of finitely many squares can be zero only in the trivial way?)

Proof. That the condition is necessary was shown above. Let it be satisfied.

The set H_0 of all sums of finitely many finite products of non zero square elements of D does not contain zero. H_0 is a halfring. By Zorn's lemma [9] H_0 is contained in a maximal halfring H of D not containing zero. Hence, $2=1^2+1^2\in H_0\subseteq H$, $2\neq 0$.

Since for any element u of D we have $u=\frac{1}{2}((u+1)^2-u^2)\in D_H$ it follows that $D_H=D$ and D has indeed the algebraic ordering which is given by

2.8. $a>b$ if and only if $a-b$ is in H.

THEOREM 2. *If the field F is algebraically ordered and if F is contained in an algebraically closed field extension Ω, then there is a really closed subfield Φ of Ω such that*

2.9. *every positive element of F is a square element of Φ.*

2.10. *Ω is algebraic over Φ.*

Proof. By Zorn's lemma [9] there is a maximal halfring H of Ω containing all positive elements of F and every non zero square element of the subfield Φ generated by H, but not zero.

We have shown above that the given ordering of F can be extended to an algebraic ordering of the field Φ such that H is the halfring of the positive elements.

If there were an element ξ of Ω that would not be algebraic over Φ then the halfring formed by the sums of finitely many nonzero square elements of $\Phi(\xi)$ with coefficients in H would be larger than H and it would contain all nonzero square elements of $\Phi(\xi)$. Because of the maximal property of H it would contain zero; hence there would be an equation.

$$0=\sum_{i=1}^{n} h_i\left(\frac{P_i(\xi)}{N(\xi)}\right)^2 \quad (h_i\in H)$$

where $N(x)$, $P_1(x)$, $\cdots$, $P_n(x)$ are non zero polynomials of $\Phi[x]$. Let m be the maximum degree of the polynomials $P_1(x)$, $\cdots$, $P_n(x)$ and let a_i be the coefficient of x^m in $P_i(x)$. Then

$$0=\sum_{i=1}^{n} h_iP_i(\xi)^2=\sum_{i=1}^{n} h_iP_i(x)^2=\sum_{i=1}^{n} h_ia_i^2,$$

contrary to the construction of H. Hence Ω is algebraic over Φ.

For every element u of H the equation $u=\xi^2$ is solvable in Ω. If ξ would not belong to Φ then the elements $a+b\xi$ with a, b contained in Φ such that $a\geqq 0$, $b\geqq 0$, $a+b>0$ forms a halfring $\overline{H}$ of Ω larger than H; it would be contained in the halfring $\overline{H}\,\overline{H}^{-1}$ containing all square elements of $\Phi(\xi)$, but not zero, which is a contradiction. (It is clear that $\overline{H}$ is a halfring larger than H, not containing zero and that $\overline{H}\,\overline{H}^{-1}$ has the same properties. Moreover, if a, $b\in\Phi$, $a\geqq 0$, $b<0$, $a^2>b^2u$, then both $-bu+a\xi$ and $(a+b\xi)(-bu+a\xi)=(a^2-b^2u)\xi$ belong to $\overline{H}$; hence $a+b\xi$ belongs to $\overline{H}\,\overline{H}^{-1}$. Now, if c, $d\in\Phi$ and $c+d\xi\neq 0$, then $(c+d\xi)^2\neq 0$,

then $(c+d\xi)^2=a+b\xi$ when $a=c^2+d^2u\in H$, and $b=2cd$, $a^2-b^2u=(c^2-d^2u)^2>0$ so that indeed $(c+d\xi)^2$ belongs to $\overline{H}\,\overline{H}^{-1}$.) Hence every element of H is a square element of Φ and 1.1, 1.2 are satisfied by Φ.

If there were a polynomial $f(x)$ of odd degree with coefficients in Φ for which the equation

$$2.11 \qquad -1 \equiv \sum_{i=1}^{s} f_i(x)^2 \,(f(x))$$

could be solved by polynomials $f_1(x), \cdots, f_s(x)$ with coefficients in Φ, then we could find among these $f(x)$ one of minimal degree $2n+1$. Upon substitution of the least remainders with regard to division by $f(x)$ it would follow that a relation 2.11 would obtain in which the maximum degree k of the polynomials $f_1(x), \cdots, f_s(x)$ would be not greater than $2n$.

Moreover, since Φ has an algebraic ordering we conclude that $n>0$ and that the coefficient of x^{2k} in

$$\sum_{i=1}^{s} f_i(x)^2$$

does not vanish, therefore the polynomial $1+\sum_{i=1}^{s} f_i(x)^2=f(x)g(x)$ is of degree $2k$ and consequently the polynomial $g(x)$ is of odd degree less than $2n+1$. But this is impossible in view of the congruence:

$$-1 = \sum_{i=1}^{s} f_i(x)^2 \,(g(x))$$

and the minimal property of $f(x)$.

Hence, for a polynomial $f(x)$ of odd degree over Φ a relation of the form 2.11 never holds. On the other hand there must be a polynomial $g(x)$ of odd degree among the irreducible divisors of $f(x)$ in $\Phi[x]$. Since Ω is algebraically closed, there is a root ξ of $g(x)$ in Ω. As was shown above, no sum of square elements of the extension field $\Phi(\xi)$ can be equal to -1. This implies that the sums of finitely many nonzero square elements of $\Phi(\xi)$ form a halfring $\overline{H}$ containing H as well as all nonzero square elements of $\Phi(\xi)$. Because of the maximal property of H we conclude that $\overline{H}$ coincides with H, $\Phi(\xi)=\Phi$, $\xi\in\Phi$, Φ is really closed.

3. The ring extensions associated with an equation. Suppose that the polynomial

3.1. $f(x)=x^n+a_1x^{n-1}+\cdots+a_n$ with coefficients $a_0=1, a_1, a_2, \cdots, a_n$ in the commutative unital ring v has the root ξ in v then

$$f(x) = f(x) - f(\xi) = \sum_{h=0}^{n} a_{n-h}(x^h - \xi^h)$$

$$= (x - \xi) \sum_{h=1}^{n} a_{n-h}\left(\sum_{j=0}^{h-1} \xi^{h-j-1}x^j \right)$$

$$= (x - \xi)\frac{f}{x - \xi}(x)$$

where

$$3.2 \qquad \frac{f}{x - \xi}(x) = \sum_{j=0}^{n-1}\left(\sum_{h=0}^{n-1-j} a_{n-j-h-1}\xi^h\right)x^j.$$

Hence every root of the polynomial 3.2 is also a root of $f(x)$. Moreover, if v is an integral domain then every root of $f(x)$ that is not equal to ξ is also a root of 3.2. And if for some polynomial $g(x)$ of degree $n-1$ over v the equation $f(x) = (x-\xi)g(x)$ holds then $g(x) = f(x)/(x-\xi)$. This is because the equation for $g(x)$ allows us to determine recursively the coefficients of $g(x)$.

The preceding remarks motivate the following formal construction.

Let us denote by $v[\xi; f]$ the v-module with basis $1, \xi, \cdots, \xi^{n-1}$ over v. The rule

$$\begin{aligned} \xi_\tau(1) &= \xi \\ \xi_\tau(\xi^i) &= \xi^{i+1} \quad (0 < i < n-1) \\ 3.3 \qquad \xi_\tau(\xi^{n-1}) &= -a_1\xi^{n-1} - a_2\xi^{n-2} - \cdots - a_n 1 \\ \xi_\tau\left(\sum_{j=0}^{n-1} b_j\xi^j\right) &= \sum_{j=0}^{n-1} b_j\xi_\tau(\xi^j) \quad (b_j \in v,\ 0 \leqq j < n) \end{aligned}$$

establishes a v-endomorphism ξ_τ of $v[\xi; f]$ satisfying the equation:

$$3.4 \qquad f(\xi_\tau) = 0$$

which is an equation for ξ_τ over v of minimal degree.

We define a multiplication on $v[\xi; f]$ by the rule:

$$\left(\sum_{h=0}^{n-1} k_h\xi^h\right)\eta = \sum_{h=0}^{n-1} k_h\xi_\tau^h(\eta)\,(\eta \in v[\xi; f])$$

which turns the v-module $v[\xi; f]$ into a commutative unital ring extension of v when the mapping $b \to b1 + 0\xi^1 + \cdots + 0\xi^{n-1}\,(b \in v)$ provides the embedding isomorphism of v into $v[\xi; f]$. The unit element of v also is the unit element of $v[\xi; f]$. Together with

$$\xi = 01 + 1\xi^1 + 0\xi^2 + \cdots + 0\xi^{n-1}$$

the ring v generates the v-ring $v[\xi; f]$ with v-basis $1, \xi, \xi^2, \cdots, \xi^{n-1}$ such that $f(\xi) = 0$. If in a commutative unital ring extension v^* of v for some element η of v the equation $f(\eta) = 0$ holds, then the mapping

$$\sum_{j=0}^{n-1} b_j\xi^j \to \sum_{j=0}^{n-1} b_j\eta^j (b_j \in v;\ 0 \leqq j < n)$$

provides a v-homomorphism of $v[\xi; f]$ into v^*.

Extending the preceding construction we define the commutative unital ring extension $v[\xi_1, \cdots, \xi_n; f]$ of v with $n!$ basis elements

$$\xi_1^{\nu_1}\xi_2^{\nu_2}\cdots\xi_n^{\nu_n} \quad (0 \leqq \nu_j < n-j; j=1, 2, \cdots, n)$$

over v as follows:

$$3.5 \qquad v[\xi_1, \cdots, \xi_n; f] = (v[\xi_1; f])[\xi_2, \cdots, \xi_n; f/(x-\xi_1)].$$

It follows that in $v[\xi_1, \cdots, \xi_n; f]$ there holds the factorization:

$$3.6 \qquad f(x) = (x-\xi_1)(x-\xi_2)\cdots(x-\xi_n)$$

of $f(x)$ into n linear factors.

THEOREM. 3 *The $n!$ permutations of the n distinct roots $\xi_1, \xi_2, \cdots, \xi_n$ of f determine automorphisms of $v[\xi_1, \cdots, \xi_n; f]$ such that the automorphism induced by the permutation π maps the polynomial expression $P(\xi_1, \xi_2, \cdots, \xi_n)$ on $P(\pi\xi_1, \cdots, \pi\xi_n)$ for any polynomial $P(x_1, \cdots, x_n)$. These $n!$ automorphisms form a group γ_n such that every element of v is fixed by every member of γ_n. The elements of v are the only elements of the ring $v[\xi_1, \cdots, \xi_n; f]$ that are fixed by γ_n.*

Proof. This is clear if $n=1$. Apply induction over n. Let $n>1$. The subset $\bar{v}$ of all elements of the ring extension that are fixed by γ_n is a subring containing v. Because of 3.5 and the induction assumption it follows that $\bar{v}$ is contained in $v[\xi_1]$. Applying a permutation automorphism interchanging ξ_1, ξ_2 to an element of $v[\xi_1]$ that is not contained in v, we obtain an element of $v[\xi_1]$ $[\xi_2]$ which is not contained in $v[\xi_1]$. Hence the theorem.

COROLLARY. (Theorem on symmetric functions.) *Let $R=v[x_1, x_2, \cdots, x_n]$ be the polynomial ring in n commuting independent variables $x_1, x_2, \cdots, x_n$ over v.* Let $s_i = \sum x_{\alpha_1}x_{\alpha_2}\cdots x_{\alpha_i} \mid 1 \leqq \alpha_1 < \cdots < \alpha_i \leqq n$ *be the i-th basic symmetric function $(1 \leqq i \leqq n)$. Then every polynomial in $x_1, x_2, \cdots, x_n$ over v that is fixed by all variable permutations (symmetric polynomial in $x_1, x_2, \cdots, x_n$) is equal to a polynomial in $s_1, s_2, \cdots, s_n$ over v.*

Proof. We note that, for the polynomial $f(x) = x^n - s_1x^{n-1} + s_2x^{n-2} - \cdots + (-1)^n s_n$,

$$3.7 \qquad f(x) = (x-x_1)(x-x_2)\cdots(x-x_n),$$

$$3.8 \qquad f(x_i) = 0 \quad (1 \leqq i \leqq n).$$

If v coincides with the rational integer ring $\mathbb{Z}$, then R is an integral domain. Hence

$$3.9 \qquad \frac{f(x_2)}{x-x_1} = 0.$$

Using the homomorphism of $\mathbb{Z}[x_1, x_2, \cdots, x_n]$ into R which sends 1 into 1, x_i into $x_i (1 \leqq i \leqq n)$ we find that 3.9 always holds. By induction over n we conclude that there is a homomorphic mapping ψ of the ring extension $T = S[\xi_1 \cdots, \xi_n; f]$ over the subring S of R generated by v and $s_1, s_2, \cdots, s_n$ which maps ξ_i onto x_i. Clearly T is generated by v and $\xi_1, \xi_2, \cdots, \xi_n$, hence there is a homomorphism σ of R onto T over v mapping x_i onto $\xi_i (1 \leqq i \leqq n)$. We have $\sigma\psi = 1_T$, $\psi\sigma = 1_R$, hence σ, ψ are isomorphisms over v. Now the corollary follows from Theorem 3.

Let $\bar{s}_1, \bar{s}_2, \cdots, \bar{s}_n$ be another set of n independent commuting variables over v and let $\bar{f}(x) = x^n - \bar{s}_1 x^{n-1} + \bar{s}_2 x^{n-2} - \cdots + (-1)^n \bar{s}_n$.

There is a homomorphism ϕ of the ring extension $\overline{T} = \overline{S}[\bar{\xi}_1, \cdots, \bar{\xi}_n; \bar{f}]$ of $\overline{S} = v[\bar{s}_1, \cdots, \bar{s}_n]$ onto T over v which maps $\bar{\xi}_i$ onto $\xi_i (1 \leqq i \leqq n)$ and hence $\bar{s}_i$ onto s_i. On the other hand, there is a homomorphism κ of R onto $\overline{T}$ over v mapping x_i onto $\xi_i (1 \leqq i \leqq n)$ and we have: $\kappa\psi\phi = 1_{\overline{T}}$, $\phi\kappa\psi = 1_T$ therefore ϕ, $\kappa\psi$ are isomorphisms over v. It follows that the homomorphic mapping of $\overline{S}$ onto S over v which maps $\bar{s}_i$ onto $s_i (1 \leqq i \leqq n)$is an isomorphism. In other words the basic symmetric functions are independent over v.

From the theorem on symmetric functions it follows that the coefficients of the polynomials

$$S_j(f)(x) = \prod_{1 \leqq \alpha_1 < \alpha_2 < \cdots < \alpha_j \leqq n} (x - (\xi_{\alpha_1} + \xi_{\alpha_2} + \cdots + \xi_{\alpha_j}))$$

of degree $\binom{n}{j}$ are in v. Moreover, if v is an integral domain in which the factorization $f(x) = \prod_{j=1}^{n} (x - \eta_j)$ obtains then the mapping of ξ_j onto $\eta_j (1 \leqq j \leqq n)$ can be extended in precisely one way to a homomorphism of $v[\xi_1, \cdots, \xi_n; f]$ onto v over v, and the equations $S_j(f)(\eta_{\gamma_1} + \cdots + \eta_{\gamma_j}) = 0$ hold whenever $1 \leqq \gamma_1 < \gamma_2 < \cdots < \gamma_j \leqq n$.

Assume that v is a field and that $S_2(f)$ has the root ξ in v. Let $d(x)$ be the greatest common divisor of the polynomials $f(x)$ and $f(\xi - x)$ in $v[x]$ with leading coefficient 1.

There holds an equation $d(x) = A(x)f(x) + B(x)f(\xi - x)$ with polynomials $A(x)$, $B(x)$ in $v[x]$. Hence in $v[\xi_1, \cdots, \xi_n; f]$:

$$d(x) = A(x)f(x) + B(x)f(\xi_1 + \xi_2 - x) + (\xi - \xi_1 - \xi_2)g(x, \xi_1 + \xi_2)$$

where $g(x, y)$ is a polynomial in two variables x, y over v. Upon substitution of ξ_2: $d(\xi_2) = (\xi - \xi_1 - \xi_2)g(\xi_2, \xi_1 + \xi_2)$.

If $d(x)$ would be a nonzero constant then $d(x) = 1 = d(\xi_2)$, hence $\xi - \xi_1 - \xi_2$ would be invertible in $v[\xi_1, \cdots, \xi_n; f]$. The same would apply to $\xi - \xi_i - \xi_k$ $(1 \leqq i < k \leqq n)$ and hence to the product.

But this product is equal to $S_2(f)(\xi)$ which is zero, a contradiction. Hence, $d(x)$ is not constant.

4. The fundamental theorem of algebra.

THEOREM 4. *Let F be a really closed field. The field extension E formed by the symbols $a + bi$ $(a, b \in F)$ with the operational rules*

$$
\begin{aligned}
&a + bi = c + di \Leftrightarrow a = c,\ b = d \\
&(a + bi) + (c + di) = (a + c) + (b + d)i \\
&(a + bi)(c + di) = (ac - bd) + (ad + bc)i \\
&(a, b, c, d \in F)
\end{aligned} \tag{4.1}
$$

is algebraically closed.

Proof. The field property of E is shown in the customary manner. The zero element of E is the symbol $0+0i$, the unit element of E is the symbol $1+0i$, the inverse of $a+bi$ is the symbol

$$\frac{a}{a^2 + b^2} + \left(\frac{-b}{a^2 + b^2}\right)i$$

provided not both of the elements a, b of F are zero. The mapping of a onto $a+0i$ provides an embedding isomorphism of F into E such that upon identification of a and $a+0i$ the field F becomes a subfield of E. The symbol $0+1i$ generates the quadratic extension E over F. Since $a+bi=(a+0i)+(b+0i)(0+1i)$, we are entitled to denote the symbol $0+1i$ by i, so that $a+bi$ is the actual sum of the element a of F and the product of the element b of F by i. The element i is a root of the irreducible quadratic equation:

$$i^2 + 1 = 0 \tag{4.2}$$

over F the other root being $-i$. Hence the complex conjugate mapping:

$$a + bi \to \overline{a + bi} = a - bi (a, b \in F) \tag{4.3}$$

establishes an involutoric automorphism of E over F. An element γ of E is in F if and only if its complex conjugate $\bar{\gamma}$ coincides with γ. The automorphism 4.3 is extended to an involutoric automorphism:

$$f(x) \to \bar{f}(x) \tag{4.4}$$

of $E[x]$ over $F[x]$ by setting

$$\bar{f}(x) = \bar{a}_0 x^n + \bar{a}_1 x^{n-1} + \cdots + \bar{a}_n \tag{4.5}$$

if

$$f(x) = a_0 x^n + a_1 x^{n-1} + \cdots + a_n (a_0, a_1, \cdots, a_n \in E). \tag{4.6}$$

The polynomial 4.6 lies in $F[x]$ if it coincides with its complex conjugate polynomial $\bar{f}(x)$.

Let us further mention that for every element $a+bi$ of $E(a, b \in F)$ the equation

$$a + bi = (\xi + \eta i)^2 (\xi, \eta \in F) \tag{4.7}$$

is solved in E by:

$$\xi = \left| \sqrt{1/2(a + \left| \sqrt{a^2 + b^2} \right|)} \right|$$

4.8

$$\eta = (\operatorname{sign} b) \cdot \left| \sqrt{1/2(-a + \left| \sqrt{a^2 + b^2} \right|)} \right|.$$

Our task is to find a root in E for every polynomial

4.9 $$f(x) = x^n + a_1 x^{n-1} + a_2 x^{n-2} + \cdots + a_n$$

with coefficients $a_1, a_2, \cdots, a_n$ in E.

Let $n = 2^s n'$ when $0 \leqq s$, $n' \equiv 1(2)$.

If it would not always be possible to find a root in E for a given nonconstant polynomial, then there would be polynomials 4.9 with minimum value of s for which no root could be found in E and among those polynomials there would be a polynomial 4.9 with minimum value of n'.

If $s = 0$ and if all coefficients $a_1, a_2, \cdots, a_n$ are real then by assumption about F we can find a root of $f(x)$ in F, a contradiction.

If there is a root η of $S_2(f)$ in E then the greatest common divisor $d(x)$ of $f(x)$ and of $f(\eta - x)$ can be formed in $E[x]$. It is not constant as we have seen previously.

There holds an equation $f(x) = d(x)e(x)$ in $E[x]$ so that every root of $d(x)$ or $e(x)$ also is a root of $f(x)$. Since there is no root of $f(x)$ in E the same applies to the polynomials $d(x)$, $e(x)$. Because of the minimal property of $f(x)$ it follows that $d(x)$ has the same degree as $f(x)$ whereas $e(x)$ is a nonzero constant. In other words $f(x) = f(\eta - x)$ if $s > 0$. Or, setting $y = x - \eta/2$ we have

$$f(x) = g(y), \qquad g(y) = g(-y), \qquad g(y) = h(y^2), \qquad f(x) = h((x - \eta/2)^2)$$

when h is a polynomial of degree $n/2$ with coefficients in E.

It follows from this argument that $S_2(f)$ has no root in E if n is even. On the other hand, the degree of $S_2(f)$ is not divisible by 2^s, hence we can find a root of $S_2(f)(x)$ in E due to the minimal property of $f(x)$.

These arguments show that n is odd and that not all coefficients of $f(x)$ are real. But the degree of $f_1(x) = f(x)\bar{f}(x)$ is $2n$, the degree of $S_2(f_1)$ is the odd number $n(2n-1)$. Since $f_1(x)$ has real coefficients, also $S_2(f_1)$ has real coefficients. Therefore, $S_2(f_1)$ has a real root and by the argument given above $f_1(x)$ has a root ξ in E. Since $0 = f_1(\xi) = f(\xi)\bar{f}(\xi)$, but by assumption $0 \neq f(\xi)$ it follows that $0 = \bar{f}(\xi)$. Forming the complex conjugate of this equation we obtain $0 = f(\bar{\xi})$ so that $f(x)$ does have the root $\bar{\xi}$ in E which is a contradiction.

Thus we have established Theorem 4.

This existence proof can be reformulated so as to yield an algorithm:

I. If $s = 0$, $f(x) \in F[x]$ then we know by assumption how to find a root of f in F.

II. If the algorithm is defined already for polynomials of odd degree less than $2n+1$ with coefficients in E and if $f(x)$ is a polynomial of degree $2n+1$ with coefficients in E, then solve $S_2(f\bar{f})(\eta) = 0$ as in I. Form $d(x)$ as above. If $[d] \equiv 1$ (2) then $[d] < 2n+1$; apply the algorithm to find a root of d in E.

It turns out to be a root of f too. If $[d]\equiv 0(2)$, then the algorithm can be applied to $e(x)=(f/d)(x)$ and provides a root of e which turns out to be also a root of f.

Thus, the algorithm is obtained for solving in E equations of odd degree over E.

III. If $s>0$ and if the algorithm is defined for solving in E equations with coefficients in E such that either the degree is not divisible by 2^s or it is smaller than the degree of f and not divisible by 2^{s+1}, then apply the algorithm to the equation $S_2(f)(\eta)=0$ and form $d(x)$ as above. Apply the algorithm to $d(x)$ in case $2^s \nmid [d]$ or $2^{s+1} \nmid [d]$ and $[d]<[f]$. Apply the algorithm to f/d in case $[d]<[f]$, $2^{s+1} \mid [d]$. In either case, a root of f is obtained. If $[d]=[f]$, then form h as above. Apply the algorithm to h, to find a root ξ of h. As above we obtain the root $\eta/2+\sqrt{\xi}$ of f for finding a root.

However, the degrees of the auxiliary equations involved may become very large. E.g. for $n=8$ we may find the degrees 8,

$$\binom{8}{2} = 28, \qquad \binom{28}{2} = 378, \qquad \binom{378}{2} = 71253.$$

But let us note that the binomial coefficient

$$\binom{n}{2^i} = \frac{2^s n' \cdot (n-1) \cdot \cdots \cdot (n-2^i+1)}{2^i \cdot 1 \cdot \cdots \cdot (2^i-1)}$$

is divisible by 2^{s-i}, but not divisible by 2^{s-i+1} for $i=0, 1, 2, \cdots s$. Hence the same arguments also apply to the auxiliary equations:

$$f(x) = 0, \qquad S_2(f)(x) = 0, \qquad S_4(f)(x) = 0, \cdots, S_{2^{s-i}}(f)(x) = 0, \cdots$$
$$S_{2^s}(f)(x) = 0.$$

Note that polynomial $S_{2^{s-1}}(f)$ is symmetric about $-(1/2)a_1$ in case $n=2^s$. Hence in that case it is of the form $g(x+(1/2)a_1)^2$ where $g(x)$ is of odd degree.

In any event we obtain considerable economy; e.g. for $n=8$ we have to form and to solve equations of degrees 8, 28, 2, 35.

Assuming that there exists an algorithm for finding the real roots of a polynomial 4.9. with real coefficients we extend it as follows to an algorithm for finding all the roots of $f(x)$

(1) If $\gcd(f, df/dx)=d(x)$ is not constant, let $(f/d)(x)=e_0(x)$, $\gcd(e_0, (df/dx))=e_1(x)$ not constant, $(e_0/e_1)(x)=f_1(x)$, $\gcd(e_{j-1}, (d^jf/dx^j))=e_j(x)$ not constant, $(e_{j-1}/e_j)(x)=f_j(x)$

$$\gcd\left(e_j, \frac{d^{j+1}f}{dx^{j+1}}\right) = 1, \quad (j>0).$$

Hence $f(x)=f_1(x)f_2(x)^2 \cdots f_j(x)^j f_{j+1}(x)^{j+1}$ when $f_1(x), f_2(x), \cdots, f_j(x), f_{j+1}(x)$ are mutually prime, separable polynomials.

The task is now to find the roots of these polynomials.

(2) $\gcd(f, df/dx)=1$, $f(x)$ has the real roots $\alpha_1, \alpha_2, \cdots, \alpha_r$, $f(x)=(x-\alpha_1)$

$(x-\alpha_2)\cdots(x-\alpha_r)g(x)$, $g(x)$ is separable and has no real root. The task is to find the roots of $g(x)$.

(3) $f(x)$ is separable and has no real root.

Find the real roots of $S_2(f(x))$ say $\beta_1<\beta_2<\cdots<\beta_\rho$. Normally speaking each of the real roots β_j is simple and in this case we have $\gcd(f(x), f(\beta_j-x)) = (x-\beta_j/2)^2+\gamma_j^2$ where γ_j is positive.

In this case the roots of $f(x)$ are the $n=2\rho$ complex numbers

$$\beta_j/2 \pm i\gamma_j \quad (1 \leqq j \leqq \rho).$$

If the real roots β_j are not all simple, a more elaborate algorithm must be carried out.

Let B_0 be the set of all roots β_j and let $\mu_0(\beta_j)$ be the multiplicity of the root β_j of $S_2(f)(x)$. Denote by A_1 the set of all elements of B_0 that are not the arithmetic mean of two distinct elements of B_0. We find that $\gcd(f(x), f(\beta-x)) = \phi_\beta(x) = \phi_\beta(\beta-x)$ is nonconstant for any β of A_1. Hence $\phi_\beta(x) = h_\beta((x-\beta/2)^2)$ where $\phi_\beta(x)$ has degree $2\mu_0(\beta)$ and h_β is a polynomial with half the degree of $\phi_\beta(x)$ such that all roots of h_β are negative, say, they are of the form: $-\gamma_{\beta_k}$ $(1 \leqq k \leqq \frac{1}{2}\mu_0(\beta))$ when γ_{β_k} is positive. Hence the roots of $\phi_\beta(x)$ are the $\mu_0(\beta)$ complex numbers $\beta/2 \pm \gamma_{\beta_k}i$. If the total number of these roots is n then the task is completed.

If the total number is less than n then we determine for each member γ of B_0 that is not contained in A_1 the number of times, say $\nu_0(\gamma)$ that $\gamma = \frac{1}{2}(\beta+\beta')$ $(\beta, \beta' \in A_1, \beta<\beta')$ and

$$\gamma_{\beta_k} = \gamma_{\beta'_{k'}} (1 \leqq k \leqq \mu_0(\beta)/2,\ 1 \leqq k' \leqq \mu_0(\beta')/2).$$

In view of the connection between f and $S_2(f)$ we find that $\mu_1(\gamma) = \mu_0(\gamma) - 2\nu_0(\gamma) \geqq 0$ when $\mu_1(\gamma)$ is not always zero.

Let us form the set B_1 of all γ's for which $\mu_1(\gamma)$ is positive.

We proceed as above, substituting B_1 for B_0, μ_1 for μ_0, A_2 for A_1 when A_2 is the subset of all members of B_1 that are not an arithmetic mean of two distinct members of B_1. In this way some further roots of $f(x)$ will be obtained. If not yet all of them are found, proceed as before until all n roots are constructed.

PSEUDOPOLYHEDRONS

J. R. GOTT, III, Mayme S. Waggener High School, Louisville, Kentucky

A regular generalized polyhedron may be defined as a network of congruent regular polygons connected vertex to vertex so that the number and arrangement of polygons around every vertex is the same. The five regular polyhedrons and the three regular tessellations are the familiar examples of regular generalized polyhedrons. In the regular polyhedrons the sum of the face angles around any vertex is less than 360°. In the regular tessellations the sum of the face angles around a vertex is equal to 360°. The regular polyhedrons approximate positively curved surfaces (spheres), while the regular tessellations approximate surfaces with 0 curvature (planes).

We may define a third group of regular generalized polyhedrons in such a way that they will share the properties of the regular polyhedrons and tessellations but will have the sum of the face angles around a vertex greater than 360°. I have called such a group of figures regular pseudopolyhedrons. I have chosen the name pseudopolyhedrons (or false polyhedrons) because while possessing many of the properties of polyhedrons they are in some aspects distinctly different. A similar convention was used in naming a specific negatively curved surface, the pseudosphere. The pseudosphere has similar properties to the sphere except that it is negatively, instead of positively, curved. By the same token it will be shown later that the pseudopolyhedrons possess similar properties to the polyhedrons except that they approximate negatively curved surfaces.

I have defined a regular pseudopolyhedron as follows:

A regular pseudopolyhedron is a network in space of congruent regular polygons fitted together vertex to vertex so that (1) every vertex is surrounded by the same number and arrangement of polygons; (2) the sum of the face angles around every vertex is greater than 360°; (3) just two polygons may meet at an edge; and (4) two polygons may share no more than one edge.

Except for condition (2), the definition is identical with that of the regular polyhedrons and the regular tessellations.

I have found seven regular pseudopolyhedrons which satisfy the conditions of this definition. These are diagrammed in Figures 1–7. Each is a repeating structure with an infinite number of faces. In the diagrams the structural form of each is presented. Each of the pseudopolyhedrons is a surface which divides

REGULAR PSEUDOPOLYHEDRONS

space into two parts. All the pseudopolyhedrons possess a periodic system of holes, so that their genus is infinite. The arrangement of polygons around any vertex approximates a negatively curved or "saddle shaped" type surface.

At the time I conducted my study I was unaware that any of these figures had been constructed before. Later research revealed that in 1926 J. F. Petrie

and H. S. M. Coxeter [1] discovered and constructed the pseudopolyhedrons in Figures 4, 6, and 7. Coxeter has called these three figures "regular skew polyhedrons." Coxeter defines "regular skew polyhedrons" in terms of symmetry properties. His definition is equivalent to my definition of pseudopolyhedrons except that he requires in addition that the arrangement of polygons around every vertex be symmetrical (by rotation) around the vertex. This additional requirement insures that the dihedral angles between all adjacent faces will be equal. Coxeter has been able to show that these three regular skew polyhedrons (Figs. 4, 6, and 7) are the only constructable figures in 3-space to satisfy his definition.

Coxeter's regular skew polyhedrons form a subset of my class of regular pseudopolyhedrons. Figures 1, 2, 3, and 5 satisfy all the definition requirements of regular pseudopolyhedrons but do not satisfy the conditions of the regular skew polyhedrons. In these figures the dihedral angles between adjacent faces are not all equal (some but not all are equal to 180°).

The difference between the two approaches is essentially a difference between criteria of regularity.

For convenience the Schäfli symbol $\{p, q\}$ will be used in the future for the generalized polyhedron of regular p-gons, q surrounding each vertex [2].

The pseudopolyhedrons of type $\{4, 5\}$ and of type $\{3, 8\}$ are formed by two planes of polygons connected by a system of holes. The other five pseudopolyhedrons, however, fill the entirety of space. They all have the unusual property of dividing space into two congruent and completely interlocking parts. The "outside" and "inside" of these figures are exactly the same shape.

FIG. 8: TABLE OF PROPERTIES

Property	*Polyhedron*	*Tessellation*	*Pseudopolyhedron*
Sum of face angles around a vertex	$<360°$	$=360°$	$>360°$
Curvature of corresponding surface	Positive	0	Negative
Number of faces	Finite	Infinite	Infinite
Genus	0	0	Infinite
Euler's Formula $V-E+F=2$	Holds	Holds	Does not hold
Divides space into	2 Parts	2 Parts	2 Parts

It is possible to obtain a graphical representation of the relationships of the regular generalized polyhedrons by graphing p (the number of sides per polygon in the network) against q (the number of polygons meeting at a vertex). (See Figure 9.) Each different regular generalized polyhedron is represented by a point on the graph having integral coordinates. The three regular tessellations lie on the hyperbola:

$$(p - 2)(q - 2) = 4.$$

The regular polyhedrons lie below and to the left of this hyperbola, and the regular pseudopolyhedrons lie above and to the right of it. This is illustrated by the graph and is proven as a theorem at the conclusion of this article.

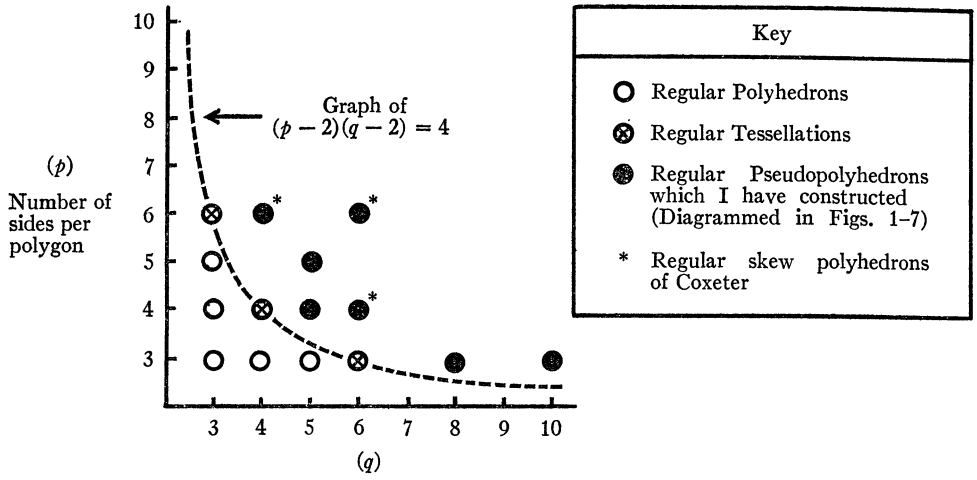

FIG. 9. Graphical representation of the Regular Generalized Polyhedrons.

While there are an infinite number of possible locations for pseudopolyhedrons on the graph, it appears that there are only a finite number of regular pseudopolyhedrons which are actually constructable in 3-space. It can be proven that no pseudopolyhedrons exist with $q=3$. (Three polygons cannot fit around a vertex to form a saddle shape surface.) An indefinitely large number of polygons of a given type may be fitted around a vertex by using a tighter and tighter zig-zag pattern. However, if a complete pseudopolyhedron is to be formed from the arrangement, the adjacent edges along the top (and bottom) of the zig-zag pattern must be separated widely enough to be connected together by edges to form the holes necessary to the network. If polygonal holes are formed, then the minimum possible separation between adjacent edges is 60° (equilateral triangular holes). The most efficient arrangement for producing these edge separations is an even zig-zag pattern (such as appears in the regular skew polyhedrons). In such a pattern q is even, but p may be either even or odd. If we construct a small unit sphere around the given vertex, we will find that the polygons cut the sphere in a series of great circle arcs which zig-zag up and down and around the sphere's equator. The critical angle between adjacent edges ($\geqq 60°$) is represented by the arc length measured on the sphere between two successive peaks in the zig-zag pattern. If we know p and q for a given network, we can compute this arc length using spherical trigonometry [5]. If the arc length is d, then:

$$\sin\frac{d}{2} = \frac{\cos\left(\frac{\pi}{2} - \frac{\pi}{p}\right)}{\cos\left(\frac{\pi}{q}\right)} \cdot \sin\left(\frac{2\pi}{q}\right).$$

Since p and q are positive, all the angles are positive. Since $d \geqq 60°$ or $\pi/3$, then $\sin(d/2) \geqq \frac{1}{2}$. The right hand side of the equation may also be simplified; thus we have

$$\frac{1}{2} \leqq \sin\frac{d}{2} = 2\sin\frac{\pi}{p}\sin\frac{\pi}{q} \quad \text{and} \quad \frac{1}{4} \leqq \sin\frac{\pi}{p}\sin\frac{\pi}{q}.$$

The only meaningful integral solutions of the equation with q even are $\{3, 8\}$, $\{3, 10\}$, $\{4, 6\}$, $\{4, 8\}$, $\{5, 4\}$, $\{5, 6\}$, $\{6, 4\}$, $\{6, 6\}$, $\{7, 4\}$, and $\{8, 4\}$. These computations were made for the most efficient type of polygon arrangement. In the actual structures any type pattern is permitted. However, if p and q are so large that even the efficient pattern does not work, then no pattern will work. We have only made computations for q even. If we remove one polygon from any zig-zag pattern and reconnect the remaining ones, there will clearly be more room between adjacent edges. For odd values of q, then the following are permissible networks: $\{3, 7\}$, $\{3, 9\}$, $\{3, 11\}$, $\{4, 5\}$, $\{4, 7\}$, $\{4, 9\}$, $\{5, 5\}$, $\{5, 7\}$, $\{6, 5\}$, $\{7, 5\}$, and $\{8, 5\}$. Thus, there can be at most 21 different pseudopolyhedrons with polygonal holes.

The difficulty with this approach is that a pseudopolyhedron may be formed which does not have polygonal holes. The example of this is in the $\{5, 5\}$ pseudopolyhedron where the holes are closed loops of edges which do not lie in one plane. Although it appears unlikely that a pseudopolyhedron could be formed with all nonpolygonal holes and all angles of separation less than 60°, the possibility does exist. No pseudopolyhedrons have as yet been discovered beyond the upper limit set by the polygonal approach.

Another puzzling phenomenon is that some possible networks which are well within the upper limits set by the angle separation problem still fail to produce pseudopolyhedrons.

What is needed is a definitive proof that will determine which combinations of sides per polygon and polygons around a vertex will actually form pseudopolyhedrons and which will not. This is an important area for future work.

The regular tessellations $\{4, 4\}$ and $\{3, 6\}$ can occur in different structural forms. In addition to covering the surface of a plane, these generalized polyhedrons may also approximate the surface of a cylinder. All the conditions of the definition are satisfied since the number and arrangement of polygons around each vertex are identical. As in several of the pseudopolyhedrons, some but not all of the dihedral angles between faces in the network are equal to 180°. Although the cylindrical structure possesses some properties different from the planar structure (the genus is 1 instead of 0), most of the properties are retained.

The curvature of the approximated surface, for example, is the same in both cases because both the cylinder and the plane have a 0 curvature.

Several pseudopolyhedrons also possess alternate structural forms. The pseudopolyhedrons of type $\{3, 8\}$ and type $\{4, 5\}$ not only can be constructed in the form of two planes connected by holes, but may also be constructed in the form of an infinite series of parallel planes of polygons connected alternately by holes and columns. The pseudopolyhedron $\{4, 6\}$ may also be constructed with rhombic holes or with alternating triangular and hexagonal holes.

Another area for future exploration is that of the semi-regular pseudopolyhedrons (defined just as regular pseudopolyhedrons only lacking the requirement that all faces in the network be congruent). One of these is a double planed, hole connected network composed of 2 squares and 2 octagons around each vertex. The semi-regular polyhedrons will possess many of the properties of the regular ones (holes, negative curvature, etc.) but should encompass a much wider range of structural forms.

In summary, pseudopolyhedrons are an interesting and unusual group of solid geometric figures. They, together with the regular polyhedrons and the regular tessellations, complete the mathematical system of constructible generalized polyhedrons. These pseudopolyhedrons create many new and challenging questions for future investigation.

THEOREMS. Let q = Number of polygons around a vertex in a given generalized polyhedron; p = Number of sides per polygon in a given generalized polyhedron; A = Vertex or face angle of polygon in generalized polyhedron; then: $A = (180° - 360°/p)$ by division of the polygon into triangles.

THEOREM I. *For every regular polyhedron:* $(p-2)(q-2)<4$. *For every regular tessellation:* $(p-2)(q-2)=4$. *For every regular pseudopolyhedron:* $(p-2)(q-2)>4$.

By definition we have: Polyhedron: $q \cdot A < 360°$; Tessellation: $q \cdot A = 360°$; Pseudopolyhedron: $q \cdot A > 360°$.

Proof for the pseudopolyhedron:

$$q \cdot A > 360° \qquad pq - 2q > 2p \text{ (since } p > 0)$$
$$q(180° - 360°/p) > 360° \qquad pq - 2(p+q) > 0$$
$$q - 2q/p > 2 \qquad pq - 2(p+q) + 4 > 4$$
$$(p-2)(q-2) > 4.$$

The other two formulas may be proven in a similar fashion. The results of this theorem are demonstrated by the graph in Figure 9.

Parts of this theorem have been proven previously [3].

THEOREM II. *The number of faces surrounding a given face is* $p(q-2)$ *in any regular generalized polyhedron.*

Proof. The given face has one face adjacent to it along each of its (p) edges. The given face also has (p) vertices; (q) polygons (faces) meet at every vertex. At each of its vertices, the given face will have ($q-3$) neighbors which touch it only at that vertex. There will thus be $p(q-3)$ neighboring faces of this type. The total number of faces surrounding a given face is thus $p+p(q-3)$ or $p(q-2)$.

THEOREM III. *Every regular pseudopolyhedron approximates a negatively curved surface.*

Proof. The approximated curved surface may be constructed so as to touch the pseudopolyhedron at every vertex. The vertices may then be connected by a series of geodesic arcs across the surface corresponding to the edges in the pseudopolyhedron. The sum of the face angles around a vertex on the pseudopolyhedron is greater than 360°, but the sum of the face angles around a vertex as measured on the surface will be equal to 360°. Thus, the angles between the geodesic arcs on the surface will be less than the corresponding angles on the pseudopolyhedron. Geodesic triangles drawn on the surface will have a sum of interior angles less than 180°. The approximated surface displays the non-euclidean geometry of a negatively curved surface and therefore has an over-all negative curvature.

In most pseudopolyhedrons the arrangement of polygons around a vertex follows the classic "saddle shape" pattern of a negatively curved surface, (as in $\{6, 4\}$). In the pseudopolyhedrons $\{4, 6\}$ and $\{6, 6\}$ the polygons around each vertex approximate a "monkey saddle" type surface. Although the curvature of a monkey saddle is 0 at the exact center, the curvature at every other point on the surface is negative. Thus, the over-all geometry of the "monkey saddle" is that of a negatively curved surface.

As an alternate idea, it has been suggested that "polygonal curvature" can be defined as $2\pi-S$, where S is the sum of face angles around a point. From this, as from the other concepts, we see that polyhedrons approximate positive curved surfaces; tessellations, 0 curved surfaces; and pseudopolyhedrons, negatively curved surfaces.

THEOREM IV. *The seven regular pseudopolyhedrons in Figures* 1–7 *are repeating structures.*

Proof. In each case it is sufficient to show that their vertex figures can be extracted from the edge system of the vertex figure of a solid tessellation or "honeycomb" of convex polyhedrons (see [6] p. 103).

For Figures 1–7.

(1) Vertex figure consists of 5 sides of a regular hexagon and three sides of a square. These edges can be extracted from the edge system of a cuboctahedron. The cuboctahedron is the vertex figure of the solid tessellation formed by regular octahedrons and tetrahedrons.

(2) Vertex figure consists of 4 sides of a regular hexagon, 3 sides of one

square and 3 sides of another square. These edges may also be extracted from the edge system of the same cuboctahedron as in 1.

(3) and (4) The vertex figures of 3 and 4 may be extracted from the edge system of a regular octahedron which is the vertex figure of the simple space filling honeycomb of cubes.

(5) The vertex figure consists of 3 sides of a trapezoid and 2 sides of an isosceles triangle. These edges form part of an irregular octahedron. Since one cross-section of this octahedron is a trapezoid with 2 parallel sides, it is indeed the vertex figure of a solid tessellation. In this case it is a space filling honeycomb of three kinds of quadrilateral prisms.

(6) The vertex figure is a skew quadrilateral which can be extracted from an irregular tetrahedron. This tetrahedron is the vertex figure for the solid tessellation of truncated octahedrons.

(7) The vertex figure is a skew hexagon which fits into a tall antiprism. This antiprism is the vertex figure of the solid tessellation of regular tetrahedrons and truncated tetrahedrons.

ON THE DIOPHANTINE EQUATION $mX^2-nY^2=\pm 1$

D. T. WALKER, Memphis State University

This paper has two major objectives. The first is to develop a formula for all solutions of the title equation, which is done in Theorems 1 through 9. Then, using this formula, the remainder of the paper deals with the second objective, which is to establish a result concerning the prime divisors of Y and n. It turns out that for n given, with two possible exceptions, Y has a prime factor not dividing n.

First we will need some well-known theory of the closely related Pell equation $X^2-DY^2=\pm 1$, which can be found in many of the current texts in Number Theory, for example [1] and [2], where solutions of the Pell equation are defined as being the numbers $x+y\sqrt{D}$ such that $x=X$ and $y=Y$ are integers satisfying that equation, and D is a positive integer not a perfect square. At all times our "integers" are assumed to be rational integers. In particular we have the following:

DEFINITION. *The solution* $x+y\sqrt{D}$ *of* $X^2-DY^2=\pm 1$, *in which integers* X *and* Y *have their least positive values, is the fundamental solution.*

The fact that powers of the fundamental solution generate all solutions of the equation is well known and is given here without proof [1] in the following two theorems.

THEOREM 1. *If* i *is a positive integer, then the formula* $x_i+y_i\sqrt{D}=(x+y\sqrt{D})^i$ *gives all solutions with positive integers* x_i, y_i *of the equation* $X^2-DY^2=1$ *whose fundamental solution is* $x+y\sqrt{D}$.

THEOREM 2. *If* i *is a positive odd integer, then the formula* $x_i+y_i\sqrt{D}=(x'+y'\sqrt{D})^i$ *gives all solutions with positive integers* x_i, y_i *of the equation* $X^2-DY^2=-1$ *when it is solvable and has* $x'+y'\sqrt{D}$ *as its fundamental solution.*

REMARK. It follows that if $X^2-DY^2=-1$ is solvable and has fundamental solution $x'+y'\sqrt{D}$, then the even powers of this solution are the solutions of $X^2-DY^2=1$. In particular $(x'+y'\sqrt{D})^2=x'^2+Dy'^2+2x'y'\sqrt{D}$ is the fundamental solution of the equation $X^2-DY^2=1$.

In this discussion, we are concerned with positive integral solutions of $mX^2-nY^2=1$ and $mX^2-nY^2=-1$, where m and n are positive integers and neither is a perfect square. We will treat both equations together as

$$mX^2-nY^2=\pm 1. \tag{1}$$

Moreover, we will develop relations between solutions of (1), when it is solvable, and solutions of the Pell equation in the form

$$R^2-mnS^2=1, \tag{2}$$

with which we will frequently be concerned.

In a manner analogous to the way in which solutions of the Pell equation were defined, we now define solutions of (1).

DEFINITION. *The number* $x\sqrt{m}+y\sqrt{n}$ *is a solution of* (1) *if* $x=X$ *and* $y=Y$ *are integers which satisfy* (1).

DEFINITION. *A solution* $x\sqrt{m}+y\sqrt{n}$ *of* (1) *is a positive solution of* (1) *if both* x *and* y *are positive.*

REMARK. We are concerned primarily with positive solutions, and it can be shown easily that if $x\sqrt{m}+y\sqrt{n}$ and $w\sqrt{m}+z\sqrt{n}$ are positive solutions of (1) then the following statements are equivalent: (i) $x<w$, (ii) $y<z$, (iii) $x\sqrt{m}+y\sqrt{n}<w\sqrt{m}+z\sqrt{n}$. Now if (1) is solvable then it has positive solutions. Then it follows from the equivalence of (i), (ii), and (iii) that among the positive solutions of (1), when it is solvable, there is one solution in which both X and Y have their least values.

DEFINITION. *A solution* $x\sqrt{m}+y\sqrt{n}$ *of* (1) *is the smallest solution of* (1) *if it is the positive solution in which both* $X=x$ *and* $Y=y$ *have their least values.*

LEMMA 1. *If* $x\sqrt{m}+y\sqrt{n}$ *is a solution of* (1), *and* $r+s\sqrt{mn}$ *is a solution of* (2), *then the product* $(xr+nys)\sqrt{m}+(yr+mxs)\sqrt{n}$ *is a solution of* (1).

Proof. $(mx^2-ny^2)(r^2-mns^2)=(\pm 1)(1)=m(x^2r^2+n^2y^2s^2)-n(y^2r^2+m^2x^2s^2)$ $=m(xr+nys)^2-n(yr+mxs)^2=\pm 1$.

LEMMA 2. *If* $x\sqrt{m}+y\sqrt{n}$ *and* $x'\sqrt{m}+y'\sqrt{n}$ *are solutions of* (1), *then the product* $(mxx'+nyy')+(xy'+x'y)\sqrt{mn}$ *is a solution of* (2).

Proof. $(mx^2-ny^2)(mx'^2-ny'^2)=(\pm 1)(\pm 1)=(mxx'+nyy')^2-mn(xy'+x'y)^2$ $=1$. In particular if $x\sqrt{m}+y\sqrt{n}$ is a solution of (1), then $(x\sqrt{m}+y\sqrt{n})^2$ is a solution of (2).

For the remainder of this discussion we will sometimes denote solutions $x\sqrt{m}+y\sqrt{n}$ and $r+s\sqrt{mn}$ of equations (1) and (2) respectively by (x, y) and (r, s), and the product of two solutions by $(x, y)\cdot(r, s)$.

The following function $F(x, y)$ has been studied by K. Petr [3] and F. Arndt [4].

DEFINITION. $F(x, y)=(x\sqrt{m}+y\sqrt{n})^2=(mx^2+ny^2)+(2xy)\sqrt{mn}$ *for a solution* $x\sqrt{m}+y\sqrt{n}$ *of* (1).

Note that the function F, which maps solutions of (1) into solutions of (2), has the following properties:

(i) $F(-x, -y)=F(x, y)$,

(ii) $F(x, -y)=\overline{F(x, y)}$, the conjugate of $F(x, y)$,

(iii) $F((x, y)\cdot(r, s))=F(x, y)\cdot(r, s)^2$ or $=F(x, y)\cdot(r+s\sqrt{mn})^2$.

LEMMA 3. *If* $F(x, y)=1$, *then* $m=1$ *or* $n=1$.

Proof. If equation (1) has the plus sign, then

$$F(x, y) = (2mx^2 - 1) + (2xy)\sqrt{mn},$$

and $2mx^2-1=1$ implies that $m=1$. Or if equation (1) has the minus sign, then

$$F(x, y) = (2ny^2 - 1) + (2xy)\sqrt{mn}, \quad \text{and} \quad 2ny^2 - 1 = 1 \text{ implies that } n = 1.$$

THEOREM 3. *If* $F(x, y)=(u, v)\cdot(u, v)$ *for some solution* $x\sqrt{m}+y\sqrt{n}$ *of* (1) *and* $u+v\sqrt{mn}$ *of* (2), *then* $m=1$ *or* $n=1$.

Proof. Let $F(x, y)=(u, v)\cdot(u, v)$, and consider

$$\begin{aligned} F((x, y)\cdot(u, -v)) &= F(x, y)\cdot(u, -v)\cdot(u, -v) \\ &= (u, v)\cdot(u, v)\cdot(u, -v)\cdot(u, -v) = 1. \end{aligned}$$

Take $(w, z)=(x, y)\cdot(u, -v)$. Thus (1) has a solution $w\sqrt{m}+z\sqrt{n}$ such that $F(w, z)=1$. Then, by Lemma 3, $m=1$ or $n=1$.

As a consequence of Lemma 1, Lemma 2, Theorem 1, and Theorem 3 we have the following

THEOREM 4. *If* $x\sqrt{m}+y\sqrt{n}$ *is a positive solution of* (1) *for both of* $m, n>1$,

then $F(x, y) = (r, s)^{2i+1}$ *for some nonnegative integer* i, *and where* $(r, s) = r + s\sqrt{mn}$ *is the fundamental solution of* (2).

THEOREM 5. *If* (1) *has a solution for both of* $m, n > 1$, *then* (1) *has a positive solution which maps under* F *into the fundamental solution of* (2).

Proof. If equation (1) is solvable, then it has a positive solution. Let $x\sqrt{m} + y\sqrt{n}$ be a positive solution of (1) and let $r + s\sqrt{mn}$ be the fundamental solution of (2). By Theorem 1 and Theorem 4, for some non-negative integer i, $F(x, y) = (r, s)^{2i+1} = (u, v)^2 \cdot (r, s)$ for some solution $u + v\sqrt{mn}$ of (2). Now consider $(w, z) = (x, y) \cdot (u, -v)$. We have $F((x, y) \cdot (u, -v)) = (r, s) \cdot (u, v)^2 \cdot (u, -v)^2 = (r, s)$. Since $F(w, z) = (r, s)$, then w and z have the same sign. So one of (w, z) and $(-w, -z)$ is positive and the other is negative. Using property (i) if necessary, the positive one, say (w', z'), is a positive solution of (1) such that $F(w', z') = (r, s)$.

It is possible that the result of the following theorem may have been obtained by K. Petr [3] by use of continued fractions.

THEOREM 6. *If* (1) *is solvable for both of* $m, n > 1$, *and has* (x, y) *as its smallest solution, then* $F(x, y) = (r, s)$ *the fundamental solution of* (2).

Proof. By Theorem 5, there is a positive solution $w\sqrt{m} + z\sqrt{n}$ of (1) such that $F(w, z) = (r, s)$. Now if the smallest solution of (1) $x\sqrt{m} + y\sqrt{n} \neq w\sqrt{m} + z\sqrt{n}$, then by Theorem 4, for some positive integer i, $F(x, y) = (r, s)^{2i+1}$.

Then $F(x, y) = [F(w, z)]^{2i+1}$, which means that

$$(x\sqrt{m} + y\sqrt{n})^2 = [(w\sqrt{m} + z\sqrt{n})^{2i+1}]^2.$$

But $x\sqrt{m} + y\sqrt{n} = (w\sqrt{m} + z\sqrt{n})^{2i+1}$ is impossible if i is a positive integer, since $x\sqrt{m} + y\sqrt{n}$ is the smallest solution of (1). Therefore $x\sqrt{m} + y\sqrt{n} = w\sqrt{m} + z\sqrt{n}$, and $F(x, y) = (r, s)$.

The converse of Theorem 6, first noted by F. Arndt [4] is given here as

THEOREM 7. *If* (1) *is solvable for both of* $m, n > 1$, *and has a positive solution* (x, y) *such that* $F(x, y) = (r, s)$ *the fundamental solution of* (2), *then* (x, y) *is the smallest solution of* (1).

Proof. If equation (1) has the plus sign then $r = 2mx^2 - 1$, or if equation (1) has the minus sign, then $r = 2ny^2 - 1$. Let $x_0\sqrt{m} + y_0\sqrt{n}$ be the smallest solution of (1). Then

$$F(x_0, y_0) = (mx_0^2 + ny_0^2) + (2x_0y_0)\sqrt{mn} = r_0 + s_0\sqrt{mn}$$

is a solution of (2) in which both of r_0, s_0 are positive integers. Now if equation (1) has the plus sign then $x_0 < x$ implies that $r_0 = 2mx_0^2 - 1 < 2mx^2 - 1 = r$ which is impossible if (r, s) is the fundamental solution of (2). Or, if equation (1) has the minus sign, then $y_0 < y$ implies that $r_0 = 2ny_0^2 - 1 < 2ny^2 - 1 = r$; again, impossible if (r, s) is the fundamental solution of (2). Therefore (x, y) is the smallest solution of equation (1).

Although not necessary for the proofs of the main results in this discussion, the following theorem concerning the equation

$$R^2 - mnS^2 = -1 \tag{3}$$

is included as a matter of interest.

THEOREM 8. *If equation* (3) *is solvable, then equation* (1), *with both of* $m, n > 1$, *is not solvable for either sign.*

Proof. Let (3) have fundamental solution $r_1+s_1\sqrt{mn}$. Then, by the remark following Theorem 2, equation (2) has fundamental solution $(r_1^2+mns_1^2)+(2r_1s_1)\sqrt{mn}$ which can be expressed as $(2r_1^2+1)+(2r_1s_1)\sqrt{mn}$ since $r_1^2-mns_1^2=-1$. Now assume both of $m, n>1$, and suppose that equation (1) with the plus sign is solvable and has smallest solution $x\sqrt{m}+y\sqrt{n}$. Then by Theorem 6, we have

$$F(x, y) = (2ny^2 + 1) + (2xy)\sqrt{mn} = (2r_1^2 + 1) + (2r_1s_1)\sqrt{mn}.$$

But $2ny^2+1=2r_1^2+1$ implies $ny^2=r_1^2$, which is impossible if n is not a perfect square. Or, with both of $m, n>1$, suppose that equation (1) is solvable with the minus sign and has smallest solution $x\sqrt{m}+y\sqrt{n}$. Again using Theorem 6, we have

$$F(x, y) = (2mx^2 + 1) + (2xv)\sqrt{mn} = (2r_1^2 + 1) + (2r_1s_1)\sqrt{mn}.$$

Here $2mx^2+1=2r_1^2+1$ implies $mx^2=r_1^2$, which is impossible since m also is not a perfect square.

THEOREM 9. *If* (1) *is solvable for both of* $m, n>1$ *and has* $x\sqrt{m}+y\sqrt{n}$ *as its smallest solution; and if* i *is a nonnegative integer, then the formula*

$$x_i\sqrt{m} + y_i\sqrt{n} = (x\sqrt{m} + v\sqrt{n})^{2i+1} \tag{4}$$

gives all positive solutions of (1).

Proof. By Theorem 6, Theorem 1, and Lemma 1, the right member of (4), which can be expressed as $(x\sqrt{m}+y\sqrt{n})(U+V\sqrt{mn})$ for some solution $U+V\sqrt{mn}$ of (2) with positive integers U and V, always gives positive solutions of (1).

Now suppose that there is a positive solution $w\sqrt{m}+z\sqrt{n}$ of (1) which is not given by (4). Then for some nonnegative integer i, we have

$$(x\sqrt{m} + y\sqrt{n})^{2i+1} < w\sqrt{m} + z\sqrt{n} < (x\sqrt{m} + y\sqrt{n})^{2i+3}. \tag{5}$$

Assume that eq. (1) has the plus sign. Here, since $x\sqrt{m}-y\sqrt{n}=1/(x\sqrt{m}+y\sqrt{n})$ is positive, (5) becomes

$$1 < (w\sqrt{m} + z\sqrt{n})(x\sqrt{m} - y\sqrt{n})^{2i+1} < (x\sqrt{m} + y\sqrt{n})^2.$$

Now let equation (1) have the minus sign. In this case

$$x\sqrt{m} - y\sqrt{n} = \frac{-1}{x\sqrt{m} + y\sqrt{n}}$$

is negative, so from inequalities (5) we have

$$1 < [(-w)\sqrt{m} + (-z)\sqrt{n}](x\sqrt{m} - y\sqrt{n})^{2i+1} < (x\sqrt{m} + y\sqrt{n})^2.$$

By Lemma 1 and Lemma 2, for either choice of sign in equation (1) the number

$$[(\pm w)\sqrt{m} + (\pm z)\sqrt{n}](x\sqrt{m} - y\sqrt{n})^{2i+1} = u + v\sqrt{mn},$$

a solution of (2) for some pair of integers u and v. Moreover, by Theorem 6, $(x\sqrt{m}+y\sqrt{n})^2 = F(x, y) = r+s\sqrt{mn}$ is the fundamental solution of (2), so that in either case of sign for equation (1) we have

$$1 < u + v\sqrt{mn} < r + s\sqrt{mn}. \tag{6}$$

We now show that both u and v are positive integers. From (6) we have $u+v\sqrt{mn} > 1$ and $0 < u-v\sqrt{mn} = 1/(u+v\sqrt{mn}) < 1$. Now it is seen from the last three inequalities that both u and v are positive. So the existence of a positive solution of (1) not given by (4) implies the existence of a solution $u+v\sqrt{mn}$ of (2), with positive integers u, v, which is less than the fundamental solution of (2), a contradiction.

REMARK. In view of the above theorems, the equation (1) is solvable if and only if the fundamental solution of (2) is the square of a solution of (1), its smallest solution, and all other positive solutions of (1), when it is solvable, can be found from formula (4).

Example. The equation $7X^2 - 13Y^2 = \pm 1$ is not solvable for either sign, since the fundamental solution of $R^2 - 91S^2 = 1$ is $1574+165\sqrt{91}$, but $1574 \neq 2(7)x^2 \pm 1$ for any integer x.

Example. The equation $13X^2 - 29Y^2 = 1$ is solvable. The fundamental solution of $R^2 - 377S^2 = 1$ is $233+12\sqrt{377}$. Then $x=3$ and $y=2$ satisfy $2(13)x^2 - 1 = 233$, $2xy = 12$, and $13x^2 - 29y^2 = 1$. So the equation of this example has $3\sqrt{13} + 2\sqrt{29}$ as its smallest solution.

Having developed a theory of solutions of equation (1), the remainder of this paper will be concerned with positive solutions of (1) having a particular property to be defined below.

The symbol $a \mid b$ (or $a \nmid b$) means that the integer a is (or is not) a factor of the integer b. Similarly if p is a prime number, the symbol $p^c \| b$ means that, for some positive integer c, $p^c \mid b$ but $p^{c+1} \nmid b$.

DEFINITION. *A solution $x_i m + y_i \sqrt{n}$ of* (1) *has property P if, for any prime number p, $p \mid y_i$ implies that $p \mid n$.*

Störmer [5] and Skolem [6] have studied a similar property P for solutions of the Pell equation $X^2 - DY^2 = \pm 1$ with results analogous to those which we shall obtain.

In the following study we will seek solutions of equation (1) having property

P, as defined above. This study also applies to cases where the prime divisors of X are divisors of m, as can be seen by changing the sign in (1) and interchanging elements of the pairs m, n and X, Y.

Now by expanding the right member of (4) we have

$$y_i = (2i+1)m^i x^{2i} y + \binom{2i+1}{3} m^{i-1} n x^{2i-2} y^3 + \cdots + n^i y^{2i+1},$$

where we see that $y \mid y_i$.

Let $y_i = yz_i$, $ny^2 = mx^2 \mp 1 = A$, where $A > 1$, and $y\sqrt{n} = \sqrt{A}$. Then from the above and (4) we obtain $x_i\sqrt{m} + z_i\sqrt{A} = (x\sqrt{m} + \sqrt{A})^{2i+1}$, where $x_0 = x$ and $z_0 = 1$.

Now let the solution $x_i\sqrt{m} + y_i\sqrt{n}$ have property P. Then if a prime $p \mid z_i$ it follows that $p \mid A$. We first seek the values of $2i+1$ for which this is possible. If $2i+1 = 1$, and hence $i = 0$, then the solution $x_i\sqrt{m} + y_i\sqrt{n} = x\sqrt{m} + y\sqrt{n}$ the smallest solution of (1) has property P. We will assume $i > 0$ and hence $2i+1 \geqq 3$. Let p be a prime divisor of $2i+1$ so that $2i+1 = pk$ for some (odd) integer k. Then $x_i\sqrt{m} + y_i\sqrt{n} = x_i\sqrt{m} + z_i\sqrt{A} = (x\sqrt{m} + \sqrt{A})^{pk}$. Since p and k are both odd, take $p = 2j+1$ and $k = 2h+1$. Now

$$x_i\sqrt{m} + z_i\sqrt{A} = [(x\sqrt{m} + \sqrt{A})^{2j+1}]^k = (x_j\sqrt{m} + z_j\sqrt{A})^{2h+1},$$

and

$$z_i = (2h+1)m^h x_j^{2h} z_j + \binom{2h+1}{3} m^{h-1} A x_j^{2h-2} z_j^3 + \cdots + A^h z_j^{2h+1}.$$

Hence $z_j \mid z_i$, and any prime divisor of z_j also divides A. But from $x_j\sqrt{m} + z_j\sqrt{A} = (x\sqrt{m} + \sqrt{A})^{2j+1}$ we see that

$$z_j = (2j+1)m^j x^{2j} + \binom{2j+1}{3} m^{j-1} x^{2j-2} A + \cdots + A^j, \tag{7}$$

and hence each prime divisor of z_j is also a divisor of $(2j+1)m^j x^{2j}$. But, since $(x, A) = (m, A) = 1$, each prime divisor of z_j is also a divisor of $2j+1$, and since the odd prime $p = 2j+1$ we have $z_j = p^r$ for some integral $r \geqq 1$. So equation (7) becomes

$$p^r = pm^j x^{2j} + \binom{p}{3} m^{j-1} x^{2j-2} A + \cdots + A^j. \tag{8}$$

Now if $p > 3$ and $r > 1$ then the second term in the right member of (8) and all following are divisible by p^2 while the first term is only divisible by p, which is impossible. Also if $p > 3$ with $r = 1$, then equation (8) leads to

$$1 = m^j x^{2j} + \frac{1}{p}\binom{p}{3} m^{j-1} x^{2j-2} A + \cdots + \frac{1}{p} A^j,$$

where each term on the right is a positive integer since $p \mid A$. But the last equa-

tion is impossible since the right member is >1. So every prime divisor p of $2i+1$ must be $p=3$.

Thus far we have shown that if $i>0$ and the solution of (1) $x_i\sqrt{m}+y_i\sqrt{n}=(x\sqrt{m}+y\sqrt{n})^{2i+1}$ has property P, then for the exponent $2i+1$ we must have

$$2i+1=3^e \tag{9}$$

where e is a positive integer.

REMARK. It is easily seen from equation (4) that an odd positive integral power of a solution of (1) is also a solution of (1).

LEMMA 4. *Let $x_u\sqrt{m}+y_u\sqrt{n}$ be any solution of* (1) *and its third power be the solution $x_v\sqrt{m}+y_v\sqrt{n}$. Moreover, let $x_v\sqrt{m}+y_v\sqrt{n}$ have property P. Then* (i) *the solution $x_u\sqrt{m}+y_u\sqrt{n}$ also has property P.*

(ii) $3mx_u^2+ny_u^2=3^s$ *for some integer* $s>1$.

(iii) $3^1\|n$.

(iv) $3\nmid y_u$.

Proof. Since

$$x_v\sqrt{m}+y_v\sqrt{n}=(mx_u^3+3nx_uy_u^2)\sqrt{m}+(3mx_u^2y_u+ny_u^3)\sqrt{n} \tag{10}$$

then (i) follows at once from the fact that $y_v=y_u(3mx_u^2+ny_u^2)$. Now by property P for $x_v\sqrt{m}+y_v\sqrt{n}$ if a prime $p\mid 3mx_u^2+ny_u^2$ then since $p\mid n$ and $(n, mx_u^2)=1$, we must have $p=3$. This proves (ii) for some positive integer s. Then $s=1$ contradicts conditions imposed on m and n, so $s>1$. Conclusions (iii) and (iv) follow at once from (ii) and the fact that $ny_u^2=3^s-3mx_u^2$.

Accordingly, since the solution $x_i\sqrt{m}+y_i\sqrt{n}=(x\sqrt{m}+y\sqrt{n})^{3^e}$ has property P then by Lemma 4, so do all solutions $(x\sqrt{m}+y\sqrt{n})^{3^f}$ have property P for all integers f such that $0\leqq f\leqq e$. In particular, the smallest solution $x\sqrt{m}+y\sqrt{n}$ and its third power, the solution $x_1\sqrt{m}+y_1\sqrt{n}$, have property P.

We now consider the smallest solution $x\sqrt{m}+y\sqrt{n}$ of (1) and its third power given by

$$x_1\sqrt{m}+y_1\sqrt{n}=(mx^3+3nxy^2)\sqrt{m}+(3mx^2y+ny^3)\sqrt{n}. \tag{11}$$

By Lemma 4 we have $3mx^2+ny^2=3^{s_1}$ for some integer $s_1>1$. Now since $3\mid n$, then for both choices of sign in (1) we have $3mx^2+ny^2=4ny^2\pm 3=3^{s_1}$, which becomes $4n'y^2\pm 1=3^{s_1-1}$, where $n'=n/3$. For some positive integer $t=s_1-1$, therefore, we have

$$n'y^2=\frac{3^t\mp 1}{4}\cdot \tag{12}$$

Conversely, if equation (1) has smallest solution $x\sqrt{m}+y\sqrt{n}$ with property P such that equation (12) is satisfied for some positive integer t and the integer $n'=n/3$, then the solution $x_1\sqrt{m}+y_1\sqrt{n}=(x\sqrt{m}+y\sqrt{n})^3$ of (1) also has property P. This can be seen by using (12) and the fact that $mx^2=ny^2\pm 1$ in equation (11) which gives

$$y_1 = 3^{t+1}y. \tag{13}$$

Furthermore, it is impossible that any solution of (1) different from the smallest solution $x\sqrt{m}+y\sqrt{n}$ and its third power $x_1\sqrt{m}+y_1\sqrt{n}$ have property P. If such solution existed it would be, because of equation (9), $(x\sqrt{m}+y\sqrt{n})^{3^e}$ for some integer $e\geqq 2$, which can be expressed as $(x_1\sqrt{m}+y_1\sqrt{n})^{3^{e-1}}=x_v\sqrt{m}+y_v\sqrt{n}$, with $e-1\geqq 1$. Now consider the solution of (1) $x_u\sqrt{m}+y_u\sqrt{n}$, of which $x_v\sqrt{m}+y_v\sqrt{n}$ is the third power, as given in (10). Then $x_u\sqrt{m}+y_u\sqrt{n}=(x_1\sqrt{m}+y_1\sqrt{n})^{3^{e-2}}$, where $e-2\geqq 0$. Now by expanding the right member of this last equation if necessary, we see easily that $y_1 \mid y_u$. It follows from equation (13) that $3 \mid y_u$, which is impossible by conclusion (iv) of Lemma 4.

Thus we have proved the following

THEOREM 10. *Among all solutions of equation* (1), *the only solutions for which property P is possible are the smallest solution* $x\sqrt{m}+y\sqrt{n}$ *and its third power* $x_1\sqrt{m}+y_1\sqrt{n}$. *The solution* $x_1\sqrt{m}+y_1\sqrt{n}$ *will have property P if and only if* $x\sqrt{m}+y\sqrt{n}$ *has property P and the integers* $n/3$ *and* y *satisfy* $(n/3)y^2=(3^t\mp 1)/4$ *for some positive integer* t.

REMARK. It is easy to find equations (1) such as $57X^2-14Y^2=1$ for which only the smallest solution $\sqrt{57}+2\sqrt{14}$ has property P. Although less common, equations (1) do exist in which both the smallest solution $x\sqrt{m}+y\sqrt{n}$ and its third power $x_1\sqrt{m}+y_1\sqrt{n}$ have property P. For example, the equation $4921X^2-1230Y^2=1$ has smallest solution $\sqrt{4921}+2\sqrt{1230}$ and third power solution $19681\sqrt{4921}+39366\sqrt{1230}$. Both solutions have property P.

In addition to having property P as defined above with regard to integers Y and n it may also happen that every prime factor of X divides m.

DEFINITION. *A solution* $x_i\sqrt{m}+y_i\sqrt{n}$ *of* (1) *has property P for both choices of sign in* (1) *if, for any prime number* p, $p \mid y_i$ *implies that* $p \mid n$ *and, for any prime number* q, $q \mid x_i$ *implies that* $q \mid m$.

Example. The (smallest) solution $3\sqrt{33}+2\sqrt{74}$ of $33X^2-74Y^2=1$ has property P for both choices of sign.

Clearly $x_1\sqrt{m}+y_1\sqrt{n}$, the third power of the smallest solution, cannot have property P for both choices of sign in (1) since by Theorem 10 this would require that both of m and n be divisible by 3 which is impossible, since m and n are relatively prime.

THEOREM 11. *If* $x_i\sqrt{m}+y_i\sqrt{n}$ *is a solution of* (1) *with property P for both choices of sign, then* $x_i\sqrt{m}+y_i\sqrt{n}$ *is the smallest solution of* (1).

In recent years LeVeque [7] and Cassels [8] have contributed to the theory of the exponential diophantine equation

$$a^x - b^y = 1, \tag{14}$$

where for nontrivial solutions we demand integers a, b, x, y all >1 and that the

equation is not $3^2-2^3=1$. Lebesgue [9] proved that for nontrivial solutions of (14) the integer y is odd. In the special case of (14) where x also is odd the results of this paper have an application. If (14) is solvable nontrivially with both of x, y odd for some integer pair a, b then the equation $aX^2-bY^2=\pm 1$ has a solution with property P for both choices of sign. So if a and b are given, then in seeking nontrivial solutions of (14) with both of x, y odd, by Theorem 11 we need only examine the smallest solution $x_0\sqrt{a}+y_0\sqrt{b}$ of the equation $aX^2-bY^2=1$.

ON THE COMPUTATION OF THE NUMBER OF ELEMENTS IN COMBINATIONS OF SETS

E. D. HOMER, New York University

1. Introduction. In computations involving finite sets (as in probability calculations, for example) it is frequently necessary to calculate the number of elements in one or more combinations of sets from available data on the number of elements in other combinations of these sets. This paper presents a computational scheme for performing such calculations which offers the following advantages:

a. The method is entirely numerical; that is, it is completely free of set-algebraic manipulations.

b. The method detects cases in which the available information is insufficient to provide all the values desired, but computes all the values possible from the given data.

c. The method can be programmed readily for digital computers.

The method presented here is an application of Ledley's "designation number" technique [2, 3] for Boolean computations. We employ "designation vec-

tors," formed almost identically to the "designation numbers" except that the former are based upon sets, the latter on Boolean variables. We have also used a different basis for the formation process than does Ledley, only for the purpose of forming sequences in a more conventional arrangement.

2. Definitions. D-1. We assume, given a finite number, n, of disjoint non-empty sets, called *simple sets*, and denoted by A_i $(i=0, 1, 2, \cdots, n-1)$. The (finite) number of elements of A_i will be denoted by $N(A_i)$. Our domain of interest is $S=\bigcup_{i=0}^{n-1} A_i$. The complement A_i' of a simple set A_i is defined relative to S: $A_i' = S - A_i$.

D-2. We define a *function of the sets* (or, simply, a *function*) to be one of the following:

a. a simple set, A_i, or

b. Any combination of one or more functions under the set operations of union ($\cup$), intersection ($\cap$), or complementation ($'$).

In a problem involving n simple sets the number of possible unique functions is $k=2^{(2^n)}$. We denote a function by:

$$f_j; j = 0, 1, \cdots, k-1; k = 2^m; m = 2^n,$$

and the set of all k functions by $F=\{f_j\}$.

D-3. Of the k possible functions of n simple sets, we are particularly interested in $m=2^n$ functions called the *elementary disjunctive functions*. An elementary disjunctive function, denoted by p_b, is the intersection of every set or its complement. Thus:

$$p_b = \bigcap_{i=0}^{n-1} B_i; b = 0, 1, \cdots, m-1;$$

where B_i is either A_i or A_i'. The set of all such functions, a subset of F, is denoted $F_p=\{p_b\}$.

D-4. We define a *basis arrangement of elementary disjunctive functions* as follows.

Let the index, b, of p_b, be an n-digit binary number. Let the digits of b be numbered from left to right from 0 to $n-1$. Then,

$$b = (\beta_0, \beta_1, \beta_2, \cdots, \beta_{n-1}),$$

where each β is either 0 or 1. (We will use b_{10} to refer to the decimal value of b, where necessary.) We form the elementary intersection functions by specifying the B_i of D-3 to be:

$$B_i = \begin{cases} A_i, & \text{if } \beta_i = 1, \\ A_i', & \text{if } \beta_i = 0. \end{cases}$$

Then, by listing the p_b's in ascending order of b, we obtain the usual "truth table" arrangement of the functions. This we call the basis arrangement of F_p.

D-5. Associated with each of the k functions of the n simple sets will be a unique *designation vector*, consisting of m binary components, $m=2^n$; and denoted by

$$\mathbf{d}(f_j) = (\delta_{j,0}, \delta_{j,1}, \delta_{j,2}, \cdots, \delta_{j,m-1}).$$

Designation vectors are formed according to the following rules:

R-1. For simple sets, the designation vectors consist of alternating equal length strings of 0's and 1's. The number of components in each string in $\mathbf{d}(A_i)$ is $2^{(n-1-i)}$. For example, if $n=4$, $m=16$:

$$\mathbf{d}(A_0) = 0\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 1\ 1\ 1\ 1\ 1\ 1\ 1\ 1$$
$$\mathbf{d}(A_1) = 0\ 0\ 0\ 0\ 1\ 1\ 1\ 1\ 0\ 0\ 0\ 0\ 1\ 1\ 1\ 1$$
$$\mathbf{d}(A_2) = 0\ 0\ 1\ 1\ 0\ 0\ 1\ 1\ 0\ 0\ 1\ 1\ 0\ 0\ 1\ 1$$
$$\mathbf{d}(A_3) = 0\ 1\ 0\ 1\ 0\ 1\ 0\ 1\ 0\ 1\ 0\ 1\ 0\ 1\ 0\ 1.$$

(In this example, as well as throughout the rest of this paper, we eliminate the customary parentheses and commas of vector notation, since no ambiguity results.)

R-1′. An alternate formation method is to view the set of vectors as a matrix, in which the columns are numbered from left to right from 0 to $m-1$. Then each column, read from top to bottom, is the binary representation of the column number.

R-2. For the complement of a single set, the designation vector is formed by performing the Boolean operation NOT ($\overline{\ \ }$) over the elements of the designation vector of the single set. Thus, continuing the previous example,

$$\mathbf{d}(A_2') = (\overline{\mathbf{d}(A_2)}) = 1\ 1\ 0\ 0\ 1\ 1\ 0\ 0\ 1\ 1\ 0\ 0\ 1\ 1\ 0\ 0.$$

R-3. The designation vector of the intersection of two or more sets is formed by performing the Boolean operation AND ($\wedge$) over the elements of the designation vectors of the sets forming the intersection:

$$\mathbf{d}(A_0 \cap A_1) = \mathbf{d}(A_0) \wedge \mathbf{d}(A_1) = 0\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 0\ 1\ 1\ 1\ 1.$$

R-4. A similar process applies for the designation vector of the union of sets, using the Boolean operation OR ($\vee$):

$$\mathbf{d}(A_0 \cup A_1) = \mathbf{d}(A_0) \vee \mathbf{d}(A_1) = 0\ 0\ 0\ 0\ 1\ 1\ 1\ 1\ 1\ 1\ 1\ 1\ 1\ 1\ 1\ 1.$$

R-5. Of course, the above rules may be combined for more complicated functions:

$$\mathbf{d}(A_0 \cup (A_1 \cap A_2') \cup A_3) = \mathbf{d}(A_0) \vee (\mathbf{d}(A_1) \wedge \mathbf{d}(A_2')) \vee \mathbf{d}(A_3)$$
$$= 0\ 1\ 0\ 1\ 1\ 1\ 0\ 1\ 1\ 1\ 1\ 1\ 1\ 1\ 1\ 1.$$

3. Characteristics of designation vectors. It can be shown that:

C-1. $\mathbf{d}(S) = 1\ 1\ 1\ \cdots\ 1\ 1$

C-2. $\mathbf{d}(S') = 0\ 0\ 0\ \cdots\ 0 = \mathbf{d}(\Phi)$

C-3. $\mathbf{d}(f_r) = \mathbf{d}(f_q)$ iff $f_r \equiv f_q$.

C-4. $\mathbf{d}(p_b) = \mathbf{e}_b$; *i.e.*, the unit vector such that

$$\delta_{b,i} = \begin{cases} 1, & \text{if } i = b_{10}, \\ 0, & \text{elsewhere: } i = 0, 1, \cdots, m-1. \end{cases}$$

For example:

b_{10}	p_b	$\mathbf{d}(p_b)$
0	$p_{0000} = A_0' A_1' A_2' A_3'$	1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
1	$p_{0001} = A_0' A_1' A_2' A_3$	0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0
2	$p_{0010} = A_0' A_1' A_2 A_3'$	0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0
.		
13	$p_{1101} = A_0 A_1 A_2' A_3$	0 0 0 0 0 0 0 0 0 0 0 0 0 1 0 0
14	$p_{1110} = A_0 A_1 A_2 A_3'$	0 0 0 0 0 0 0 0 0 0 0 0 0 0 1 0
15	$p_{1111} = A_0 A_1 A_2 A_3$	0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 1

C-5. It is well known that the set of elementary disjunctive functions is disjoint. This fact can be verified by applying R-3 to C-4, obtaining $\mathbf{d}(\Phi)$ for the intersection of any two or more p_b's.

C-6. It is well known that any member of F may be formed by the union of elementary disjunctive functions. Let $\{p_j\}$ be a subset of F_p. Then, given a member of F, say f_j, it is always possible to find a $\{p_j\}$ such that

$$f_j \equiv \bigcup_j \{p_j\},$$

which is, of course, the disjunctive canonical form, and, by C-3,

$$\mathbf{d}(f_j) = \mathbf{d}(\bigcup_j \{p_j\}) = \bigvee_j \{\mathbf{d}(p_j)\} = \bigvee_j \{\mathbf{e}_j\}.$$

Therefore, the designation vector of any function in F is the logical sum of some of the unit vectors.

C-7. In the expression

$$\mathbf{d}(f_j) = (\delta_{j,0}, \delta_{j,1}, \delta_{j,2}, \cdots, \delta_{j,m-1}) = \mathbf{d}(\bigcup_j \{p_j\}), \qquad p_b \in \{p_j\} \text{ iff } \delta_{j,b} = 1.$$

4. Calculating the number of elements. It is well known (see [4], for example) that for arbitrary disjoint sets, X_i: $N(\bigcup_i X_i) = \sum_i N(X_i)$. Therefore, by C-6 and C-5:

$$N(f_j) = N(\bigcup_j \{p_j\}) = \sum_j \{N(p_j)\}.$$

It is convenient, however, to work with the set F_b, rather than with the subset $\{p_j\}$. We may write:

$$N(f_j) = \sum_{b=0}^{m-1} \alpha_{j,b} N(p_b),$$

where:

$$\alpha_{j,b} = \begin{cases} 1, & \text{if } p_b \in \{p_j\} \\ 0, & \text{otherwise.} \end{cases}$$

But, from C-7, $p_b \in \{p_j\}$ iff $\delta_{j,b} = 1$. Therefore $\alpha_{j,b} = \delta_{j,b}$ and

$$N(f_j) = \sum_{b=0}^{m-1} \delta_{j,b} N(p_b). \tag{1}$$

If we define the column vector

$$\mathbf{N}(P) = [N(p_0), N(p_1), \cdots, N(p_{m-1})]^t,$$

where "t" denotes "transpose," then we may write equation (1) as

$$N(f_j) = \mathbf{d}(f_j)\mathbf{N}(P). \tag{2}$$

We wish to calculate the number of elements in certain functions. Let us call the set of these functions $F_s = \{f_s\}$, a subset of F. Let us assume that there are g functions in F_s; $0 < g \leqq m$. We may solve a series of equations (2) for all $j \in s$. It is more convenient to represent the series of equations to be solved in matrix form:

$$\mathbf{N}(F_s) = \mathbf{D}(F_s)\mathbf{N}(P), \tag{3}$$

where $\mathbf{D}(F_s) = [\mathbf{d}(f_{s1}), \mathbf{d}(f_{s2}), \cdots, \mathbf{d}(f_{sg})]^t$ and $\mathbf{N}(F_s) = [N(f_{s1}), N(f_{s2}), \cdots, N(f_{sg})]^t$.

Equation (3) can be used only when the given information includes $\mathbf{N}(P)$, that is, the number of elements in all the elementary disjunctive functions. Usually, this is not the case. Therefore, let us call the set of functions for which we know the number of elements $F_a = \{f_a\}$, a subset of F such that all the f_a's are not necessarily p_b's. We may substitute in (3), obtaining $\mathbf{N}(F_a) = \mathbf{D}(F_a)\mathbf{N}(P)$. If $\mathbf{D}(F_a)$ is nonsingular, we may solve for $\mathbf{N}(P)$:

$$\mathbf{N}(P) = \mathbf{D}^{-1}(F_a)\mathbf{N}(F_a). \tag{4}$$

Substituting from equation (4) into equation (3), we get

$$\mathbf{N}(F_s) = \mathbf{D}(F_s)\mathbf{D}^{-1}(F_a)\mathbf{N}(F_a). \tag{5}$$

Equation (3) can be seen to be a special case of equation (5), for $\mathbf{D}(P) = \mathbf{D}^{-1}(P) = I$, the identity matrix.

Equation (5) may be used whenever $\mathbf{D}(F_a)$ is nonsingular. Thus a sufficient condition for the computation of $\mathbf{N}(F_s)$ is that F_a contain at least m functions whose designation vectors are linearly independent, but this condition is not necessary. If $\mathbf{D}(F_s)$ contains one or more columns which are all zero, it may be possible for F_a to contain less than m values.

Suppose that we have a set of available data containing, say, q members, with $q<m$. (Note that if we have available m values, but $\mathbf{D}(F_a)$ is singular, then we may eliminate the functions corresponding to the dependent designation vectors, and proceed with the remaining q functions.) We add $m-q$ functions to the set, to form a new set F_{a*}, subject to the constraint that the added functions, $F_d=\{f_d\}$, be such that $\mathbf{D}(F_{a*})$ be nonsingular. The number of elements in each of the f_d's is, of course, unknown. We may assume, with no loss of generality, that the added designation vectors form the *last* $m-q$ rows of $\mathbf{D}(F_{a*})$.

We are now concerned with this question: What is the set of functions, F_{s*}, for which $\mathbf{N}(F_{s*})$ can be calculated on the basis of the limited information in $\mathbf{N}(F_a)$? To determine this we compute $\mathbf{D}^{-1}(F_{a*})$. Call $\mathbf{C}$ the submatrix of $\mathbf{D}^{-1}(F_{a*})$ formed of all the rows and the last $m-q$ columns of $\mathbf{D}^{-1}(F_{a*})$. Designate by W the set of all row indices of $\mathbf{C}$ for which the row contains at least one nonzero entry. Then we may find the number of elements in any f_{s*} if $\mathbf{d}(f_{s*})$ meets this criterion:

$$\delta_{s*,j} = \begin{cases} 0, \text{ if } j \in W \\ 0, \text{ or } 1 \text{ otherwise.} \end{cases}$$

If the number of indices in W is w, then the maximum number of functions in F_{s*} is $2^{(m-w)}$. Obviously, if w equals m, F_{s*} is empty.

5. Examples.

Example 1. Let $S=A_0\cup A_1\cup A_2$. Here $n=3$, $m=8$. Let F_a consist of 6 members:

f_a	$N(f_a)$
$f_{a0} = A_0 \cup A_1' \cup A_2$	230
$f_{a1} = (A_0' \cap A_2) \cup (A_1 \cap A_2)$	100
$f_{a2} = A_0'$	140
$f_{a3} = A_0 \cup (A_1' \cap A_2')$	140
$f_{a4} = A_0 \cup A_1$	220
$f_{a5} = (A_0 \cap A_1 \cap A_2) \cup (A_0' \cap A_1' \cap A_2')$	10

Find the number of elements in:

$$f_{s0} = A_0' \cap A_1', \quad f_{s1} = A_1 \cap A_2, \quad f_{s2} = A_0' \cup (A_1 \cap A_2), \quad f_{s3} = A_2'.$$

Solution: First, form the designation numbers of the simple sets

$$\mathbf{d}(A_0) = 0\ 0\ 0\ 0\ 1\ 1\ 1\ 1$$
$$\mathbf{d}(A_1) = 0\ 0\ 1\ 1\ 0\ 0\ 1\ 1$$
$$\mathbf{d}(A_2) = 0\ 1\ 0\ 1\ 0\ 1\ 0\ 1.$$

Next, form the designation vectors of the functions in F_a:

$$\begin{aligned}
\mathbf{d}(f_{a0}) &= 1\ 1\ 0\ 1\ 1\ 1\ 1\ 1\\
\mathbf{d}(f_{a1}) &= 0\ 1\ 0\ 1\ 0\ 0\ 0\ 1\\
\mathbf{d}(f_{a2}) &= 1\ 1\ 1\ 1\ 0\ 0\ 0\ 0\\
\mathbf{d}(f_{a3}) &= 1\ 0\ 0\ 0\ 1\ 1\ 1\ 1\\
\mathbf{d}(f_{a4}) &= 0\ 0\ 1\ 1\ 1\ 1\ 1\ 1\\
\mathbf{d}(f_{a5}) &= 1\ 0\ 0\ 0\ 0\ 0\ 0\ 1.
\end{aligned}$$

To this append two additional designation vectors, chosen to make $\mathbf{D}(F_{a*})$ nonsingular. We have chosen:

$$\mathbf{d}(f_{d0}) = 0\ 0\ 1\ 1\ 0\ 0\ 1\ 0, \mathbf{d}(f_{d1}) = 0\ 1\ 1\ 1\ 0\ 1\ 1\ 1.$$

The choice is not unique. The vectors chosen are such that

$$f_{d0} = (A_0' \cap A_1) \cup (A_1 \cap A_2') \quad \text{and} \quad f_{d1} = A_1 \cup A_2,$$

although this is not important.

We now form

$$\mathbf{D}(F_{a*}) = \begin{bmatrix} \mathbf{D}(F_a) \\ \mathbf{D}(F_d) \end{bmatrix},$$

and compute its inverse:

$$\mathbf{D}(F_{a*}) = \begin{bmatrix}
1 & 1 & 0 & 1 & 1 & 1 & 1 & 1\\
0 & 1 & 0 & 1 & 0 & 0 & 0 & 1\\
1 & 1 & 1 & 1 & 0 & 0 & 0 & 0\\
1 & 0 & 0 & 0 & 1 & 1 & 1 & 1\\
0 & 0 & 1 & 1 & 1 & 1 & 1 & 1\\
1 & 0 & 0 & 0 & 0 & 0 & 0 & 1\\
0 & 0 & 1 & 1 & 0 & 0 & 1 & 0\\
0 & 1 & 1 & 1 & 0 & 1 & 1 & 1
\end{bmatrix},$$

$$\mathbf{D}^{-1}(F_{a*}) = \begin{bmatrix}
1 & -1 & 0 & -1 & 0 & 1 & 0 & 0\\
-2 & 2 & 1 & 3 & -1 & -2 & 0 & 0\\
-2 & 1 & 1 & 2 & 0 & -1 & 0 & 0\\
3 & -2 & -1 & -4 & 1 & 2 & 0 & 0\\
-2 & 2 & 1 & 3 & 0 & -2 & 0 & -1\\
3 & -3 & -1 & -4 & 1 & 2 & -1 & 1\\
-1 & 1 & 0 & 2 & -1 & -1 & 1 & 0\\
-1 & 1 & 0 & 1 & 0 & 0 & 0 & 0
\end{bmatrix}$$

We examine the submatrix

$$\mathbf{C} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ 0 & -1 \\ -1 & 1 \\ 1 & 0 \\ 0 & 0 \end{bmatrix}$$

consisting of the last two columns of $\mathbf{D}^{-1}(F_{a*})$, and note the indices of the rows which contain non-zero entries (noting that here, as throughout this paper, indices have zero origin). We find that $W = \{4, 5, 6\}$.

We now compute the designation vectors of the functions in F_s:

$$\mathbf{d}(f_{s0}) = 1\ 1\ 0\ 0\ 0\ 0\ 0\ 0$$
$$\mathbf{d}(f_{s1}) = 0\ 0\ 0\ 1\ 0\ 0\ 0\ 1$$
$$\mathbf{d}(f_{s2}) = 1\ 1\ 1\ 1\ 0\ 0\ 0\ 1$$
$$\mathbf{d}(f_{s3}) = 1\ 0\ 1\ 0\ 1\ 0\ 1\ 0.$$

The first three functions are admissible in F_{s*}, since their designation vectors have zeros in positions j, $j \in W$, $W = \{4, 5, 6\}$. The last function, however, is not admissible, since $\delta_{s3,4}$ and $\delta_{s3,6}$ are not zero.

Solving equation (5), we get

$$\mathbf{N}(F_{s*}) = \mathbf{D}(F_{s*})\mathbf{D}^{-1}(F_{a*})\mathbf{N}(F_{a*})$$

$$\mathbf{N}(F_{s*}) = \begin{bmatrix} 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 \\ 1 & 1 & 1 & 1 & 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & -1 & 0 & -1 & 0 & 1 & 0 & 0 \\ -2 & 2 & 1 & 3 & -1 & -2 & 0 & 0 \\ -2 & 1 & 1 & 2 & 0 & -1 & 0 & 0 \\ 3 & -2 & -1 & -4 & 1 & 2 & 0 & 0 \\ -2 & 2 & 1 & 3 & 0 & -2 & 0 & -1 \\ 3 & -3 & -1 & -4 & 1 & 2 & -1 & 1 \\ -1 & 1 & 0 & 2 & -1 & -1 & 1 & 0 \\ -1 & 1 & 0 & 1 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 230 \\ 100 \\ 140 \\ 140 \\ 220 \\ 10 \\ N(f_{a0}) \\ N(f_{a1}) \end{bmatrix}$$

$$\mathbf{N}(F_{s*}) = \begin{bmatrix} 60 \\ 40 \\ 150 \end{bmatrix} = \begin{bmatrix} N(f_{s0}) \\ N(f_{s1}) \\ N(f_{s2}) \end{bmatrix}.$$

Example 2. As a second example, we consider a problem which has appeared in [1] and in [4], and apparently stems from the 1935 Joint Associateship Examination for Actuaries.

"Certain data obtained from a study of a group of 1000 employees in a

cotton mill, as to their race, sex, and marital status, were unofficially reported as follows: 525 colored lives; 312 male lives; 470 married lives; 42 colored males; 147 married colored; 86 married males; 25 married colored males. Test this classification to determine whether the numbers reported in the various groups are consistent."

We define the sets and their designation vectors as

$$C = \text{colored lives}; \quad \mathbf{d}(C) = 0\ 0\ 0\ 0\ 1\ 1\ 1\ 1$$
$$M = \text{male lives}; \quad \mathbf{d}(M) = 0\ 0\ 1\ 1\ 0\ 0\ 1\ 1$$
$$W = \text{married lives}; \quad \mathbf{d}(W) = 0\ 1\ 0\ 1\ 0\ 1\ 0\ 1.$$

From the given data,

$$\mathbf{N}(F_a) = \begin{bmatrix} N(S) = 1000 \\ N(C) = 525 \\ N(M) = 312 \\ N(W) = 470 \\ N(C \cap M) = 42 \\ N(C \cap W) = 147 \\ N(M \cap W) = 86 \\ N(C \cap M \cap W) = 25 \end{bmatrix}, \qquad \mathbf{D}(F_a) = \begin{bmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 0 & 0 & 1 & 1 & 0 & 0 & 1 & 1 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}.$$

We calculate

$$\mathbf{D}^{-1}(F_a) = \begin{bmatrix} 1 & -1 & -1 & -1 & 1 & 1 & 1 & -1 \\ 0 & 0 & 0 & 1 & 0 & -1 & -1 & 1 \\ 0 & 0 & 1 & 0 & -1 & 0 & -1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & -1 \\ 0 & 1 & 0 & 0 & -1 & -1 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & -1 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

Suppose that we now calculate $\mathbf{N}(P) = \mathbf{D}^{-1}(F_a)\mathbf{N}(F_a)$.

The first value calculated, $N(p_0)$, shows that the data are inconsistent, for $N(p_0) = -57$, and the number of elements in a function of sets cannot be negative.

HAMILTON CIRCUITS OF CONVEX TRIVALENT POLYHEDRA (UP TO 18 VERTICES)

JOSHUA LEDERBERG, Stanford University School of Medicine

In a study of the graphs of chemical structures [1, 2], it became of interest to ascertain the Hamilton circuits (a closed circuit of edges through all the vertices) of trivalent graphs, and especially of the convex polyhedra. Tait [3] had conjectured that these polyhedra always had Hamilton circuits—for brevity we will now say had *circuits*. In [4], however, Tutte has demonstrated a counter-example with 46 vertices. Between about 12 or 14 vertices and 46, the territory has hardly been explored.

Grace [5] has recently presented a computer tabulation of the polyhedra through 18 vertices, affording a convenient opportunity to scan them for circuits, which were found in every instance. As Grace has noted, his criterion for isomorphism, "equisurroundedness" of the sets of faces is not strictly sufficient and his list may still be incomplete. As the isomorphism of *circuits* is fairly readily computed, this approach may be useful in further extensions of such studies.

The work needed to demonstrate a circuit is curtailed by the reducibility of any triangular face: A circuit through a triangle is equivalent to that through a node:

That is to say, to describe a circuit a triangular face can be shrunk down to a node. In effect, by induction, if all n-hedra have circuits, so will all $(n+2)$-hedra with triangular faces, and we need only examine those without. Table 1 shows that only 55 forms need to be studied.

Grace displayed the polyhedra as face-incidence lists. A computer program translated these into vertex-incidence lists. Each vertex being identified as a face-triple, those vertices are joined which share two faces. The vertex-incidence

TABLE 1. Count of Trivalent Convex Polyhedra

Vertices n	*Faces* f	*Count Total* [5]	*Count No Triangles Present*	*Count No 3-connected Regions*
4	4	1	0	0
6	5	1	0	0
8	6	2	1	1
10	7	5	1	1
12	8	14	2	2
14	9	50	5	4
16	10	233	12	10
18	11	1249	34	26
		1555	55	44

list was then processed by a binary chained search of alternative paths; hence the search is always $\ll 2^n$, in contrast to the $n!$ scope of a systematic permutation of the vertices. (A much more efficient algorithm has been discovered and is outlined as an appendix.)

Table 2 displays a circuit for each of the 55 polyhedra. The other polyhedra of order $\leqq 18$, and some of higher order can be developed from these by expanding nodes into triangles, a process that can be iterated.

The circuits lend themselves to a compact code from which the graph of a polyhedron is quickly constructed. Draw a polygon with vertices marked $1(1)n$. Each successive character of the code denotes the span of a chord drawn from the next *vacant* vertex. Thus the prism would be 2, 3, 2 or *BCB*, and Hamilton's own example, the dodecahedron, is *DJGDMJGDGD*. There will be $n/2$ characters (to be sure the last one is redundant, being fixed by its predecessors). The letters *A*, *B*, *C* · · · stand for spans of 1, 2, 3 · · · vertices. *A* and *B* do not appear in our list; *A* would connote a self-looped edge and *B* a triangular face.

Only one of the sometimes numerous circuits of each polyhedron is shown: it is merely the first one discovered by the computer search, but it has been placed in canonical form with respect to rotation and reflection of the polygon [2].

The complete list of the Hamilton circuits for each graph of Table 2 gives further insight into the composition of circuit-free graphs. Extracting one node from a polyhedron leaves a cut graph with three cut edges, e.g., a triangular region is the residue of a tetrahedron. In the first instance, in general such a residue will have the same facility for admitting a circuit as does an isolated node, depending on the set of circuits found in the polyhedron. Thus, except for *CGDIGDFD* (Grace's 16–55) all the polyhedra where $n \leqq 16$ have this property. Hence for finding circuits, any other 3-connected region can be replaced by a single node. By induction only the 44 forms counted in Table 1 need be considered for $n \leqq 18$.

CGDIGDFD, (Fig. 1a) which is the same as Tutte's graph N_2 [4], has three (symmetrically equivalent) edges that are obligatory in any Hamilton circuit. It is the simplest with such a property.

Tutte produced a 46-node circuit-free graph by replacing three nodes of a tetrahedron with 3 15-node residues so that 3 obligatory edges converged on one node in a self-contradictory way. Along the same lines a 38-node, circuit-free graph can be composed by replacing two nodes of *CFDEC*, the pentagonal prism, with two 15-node residues so as to confront two obligatory edges with two that, as pointed out by Tutte, are mutually exclusive. In an independent study, David Barnette has already discovered this graph [6].

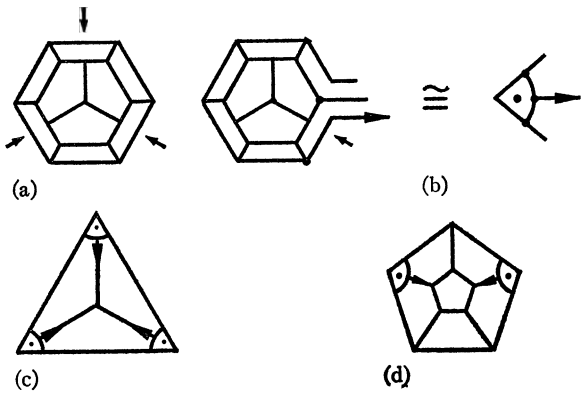

FIG. 1. Composition of non-Hamiltonian polyhedra. (a) 16*CGDIGDFD* which is Tutte's graph N_2[4]. The marked edges are obligatory in any circuit. (b) a 15-node residue with an obligatory edge as marked. (c) and (d) are two non-Hamiltonian polyhedra of 46 and 38 nodes respectively.

If we accept the enumeration of polyhedra for $n \leqq 16$, on which Grace concurs with Brückner [7], or merely that we know the 4-connected cases (as in table 2), a similar line of reasoning leads to an inferential argument for the conclusion that every 18-node polyhedron has a circuit. (We should say, more precisely, *cyclically* 4-connected as defined by Tutte [8]: "a *cyclically k-connected* graph cannot be broken up into two separate parts, each containing a polygon, by the removal of fewer than k edges.") Each of the graphs was searched by a computer program for subgraphs obtained by extracting any node-pair, and the circuit-forming properties of the subgraphs examined. None of the subgraphs was of a kind that would disqualify a pairwise combination of them from containing a circuit (cf. Tutte's arguments [8]). On the other hand, from Euler's formula, every 18-node polyhedron must (a) contain no 3-connected and at least one 4-connected subgraph which has 14 or fewer nodes, and would therefore fall within the scope of the search, or (b) is derived from a graph with at least one 3-connected region, a case already disposed of through $n=16$. The further

TABLE 2. Listing of Hamilton circuits

(Included are convex trivalent polyhedra with $n \leqq 18$ vertices. Only polyhedra with no triangular face are listed. See text for code. Each character group stands for one polyhedron.)
* marks 3-connected forms; the remainder are 4-connected.

application of this technique should make it possible to anticipate the smallest non-Hamiltonian polyhedron from the properties of the 4- and 5-connected polyhedra of the next lower order. Since these, by definition, all have circuits, it would be feasible to generate them on the computer by reasonably efficient combinatorial schemes to whatever order is required.

Appendix: Algorithm for finding Hamilton circuits of a cyclic graph.

This is illustrated for an undirected, trihedral graph but should be generalized without difficulty in an obvious way. The input is a description of the connectivity of the graph. The essence of the routine is to build a table of sets of edges so that just two edges incident on each node appear in any row of the table. The first node is chosen arbitrarily. Its three incident edges are marked *current* and *open*. The circuit-fragment table is started with three rows by listing the 3 pairwise choices among the current edges.

1. Select an open edge. The two adjacent edges become the trial edges.
2. How many trial edges match the current list: none, one, or two?
 a. If none match, close the selected edge and replace it on the current open list by the two trial edges. Scan the circuit-fragment table. Each row in which the selected edge appears is replaced by two rows, one for each trial edge. Each remaining row is replaced by one row showing both trial edges. Go to 1.
 b. If one matches, a circuit of the graph has been closed. Scan the circuit-fragment (c.f.) table contrasting the matched edge with the selected edge. Each c.f. where neither appears is deleted. If one of the two appears on a c.f., this is augmented by the trial edge. If both appear, the c.f. row stands as is unless a tracing of the c.f. shows it to be prematurely closed, whereupon it is deleted. Go to 1.
 c. If both match two adjacent faces of the graph have been closed. The preceding subroutine is revised in an obvious way to close out both matched edges: those c.f. rows are retained which are compatible with the indicated edge allocations. Go to 1.

The process is terminated when the open edge list is vacated. If this leaves some nodes unused, no Hamilton circuit is possible. Otherwise, the final closure of circuit-fragments leaves a table of circuits. This must still be scanned to separate the Hamiltonian circuits from the set of pairwise disjoint circuits.

The efficiency of the algorithm depends on keeping the current c.f. table as small as possible. This is accomplished by a lookahead routine which scans prospective choices of current edges to seek the promptest closure of a face.

For an example, Tutte's 46 node non-Hamiltonian graph has been searched exhaustively. This required a c.f. table of 12,477 rows consuming 29 seconds of a program on IBM 7090. Searches yielding all the circuits of other large Hamiltonian graphs required a comparable effort.

This procedure may have some utility for studies on classification, isomorphisms, and symmetries of abstract graphs and other network problems for which the set of Hamilton circuits is often an advantageous approach. A complete description of the computer program is available from the author.

This work has been supported by a grant from NASA (NsG 81-60) for studies on automated experimental analysis. Computations were run on an IBM 7090 at the Stanford Computation Center with support from the National Science Foundation, under grant NSF-GP-948.

SPAN OF DERIVATIVES OF POLYNOMIALS

A. MEIR AND A. SHARMA, University of Alberta

1. We denote by π_n the class of polynomials $P(x)$ of exact degree n having n real zeros $x_1 \leqq x_2 \leqq \cdots \leqq x_n$ and, following [1] we define the span $\sigma(P)$ of the polynomial $P(x)$ to be $x_n - x_1$. Robinson has considered the problem of determining the maximum span of the kth derivative of polynomials of π_n, when the span of the polynomial itself was given. In fact he proved, that if

$$\sigma(P) \leqq 2 \tag{1}$$

then max $\sigma(P^{(k)})$ for $1 \leqq k \leqq n-2$ is obtained when $P(x) = c(1-x)^p(1+x)^{n-p}$. For $k = n-2$, $n-3$ he determined the exact values of the corresponding spans.

The object of this note is to replace the condition (1) by restrictions on the first or second moments of the zeros $x_1, x_2, \cdots, x_n$. Related problems under similar conditions have been treated in [2; p. 140, Theorems 6.7.2, 6.7.3, and p. 379, Problem 38]. One of the problems considered therein is about the distribution of points $x_1, x_2, \cdots, x_n$ on the real line which maximize the absolute value of the Vandermondian $V(x_1, x_2, \cdots, x_n)$ under the restriction

$$\frac{1}{n}\sum_{i=1}^{n} x_i^2 \leqq 1.$$

2. We prove the following results:

THEOREM 1. *Let π_n^1 be the subclass of polynomials $P(x) \in \pi_n$ with zeros $\{x_i\}_{i=1}^n$ satisfying the conditions*

$$x_i \geqq 0, \quad i = 1, 2, \cdots, n; \qquad n^{-1}\sum_{i=1}^{n} x_i \leqq 1, \tag{2}$$

and let $k \leqq n-2$. Then

$$\max_{P\in\pi_n^1} \sigma(P^{(k)}) = n - k. \tag{3}$$

and the maximum is attained only for $P(x)=cx^{n-1}(x-n)$, *where* $c\neq 0$ *is an arbitrary constant.*

THEOREM 2. *Let* π_n^2 *be the subclass of polynomials* $P(x)\in\pi_n$ *with zeros* $\{x_i\}_{i=1}^n$ *satisfying the condition*

$$n^{-1}\sum_{i=1}^{n} x_i^2 \leqq 1, \tag{4}$$

and let $k\leqq n-2$. *Then*

$$\max_{P\in\pi_n^2} \sigma(P^{(k)}) = \left[\frac{2(n-k)(n-k-1)}{n-1}\right]^{1/2} \tag{5}$$

and the maximum is attained only for polynomials of the form

$$P(x) = cx^{n-2}\left(x^2 - \frac{n}{2}\right) + Q(x) \tag{6}$$

where $c\neq 0$ *is an arbitrary constant and* $Q(x)$ *is a polynomial of degree* $\leqq k-1$.

3. Proofs. Denote by $\xi_1\leqq\xi_2\leqq\cdots\leqq\xi_{n-k}$ the necessarily real zeros of $P^{(k)}(x)$, and set $P(x)=c(x^n-s_1x^{n-1}+s_2x^{n-2}-\cdots)$. Then it is well known that

$$s_1 = \sum_{i=1}^{n} x_i, \qquad s_2 = \sum_{1\leqq i<j\leqq n} x_ix_j \tag{7}$$

and easily seen that

$$\sum_{j=1}^{n-k} \xi_j = \frac{n-k}{n} s_1, \tag{8}$$

$$\sum_{1\leqq i<j\leqq n-k} \xi_i\xi_j = \frac{(n-k)(n-k-1)}{n(n-1)} s_2. \tag{9}$$

From (8) and (9) one obtains

$$\Lambda \equiv \sum_{1\leqq i<j\leqq n-k} (\xi_j - \xi_i)^2 = \frac{(n-k-1)(n-k)^2}{n(n-1)}\left\{\sum_{i=1}^{n} x_i^2 - n^{-1}s_1^2\right\}. \tag{10}$$

To prove Theorem 1 we observe that $\xi_i\geqq 0$ for all i. Then by (8) and (2)

$$\max_i \xi_i \leqq s_1\frac{n-k}{n} \leqq n-k$$

with equality only if $s_1=n$ and $\xi_1=\cdots=\xi_{n-k-1}=0$ and $\xi_{n-k}=n-k$. Hence $\sigma(P^{(k)})\leqq n-k$ with equality only in the above case. Thus the maximum span is attained for $P^{(k)}(x)=cx^{n-k-1}(x-n+k)$. Since the zeros of $P(x)$ are real and $\geqq 0$,

$P(x)$ must have $n-1$ zeros at $x=0$, so that $s_1=x_n=n$. Thus $P(x)$ is of the form $P(x)=cx^{n-1}(x-n)$. In fact

$$[x^{n-1}(x-n)]^{(k)} = \frac{n!}{(n-k)!}x^{n-k-1}(x-n+k).$$

In order to prove Theorem 2, we observe from (4) and (10) that

$$\Lambda \leqq \frac{(n-k-1)(n-k)^2}{n-1} \tag{11}$$

with equality only if $s_1=0$ and $\sum_{i=1}^{n} x_i^2=n$. Now, since $\sigma\equiv\sigma(P^{(k)})=\xi_{n-k}-\xi_1$ we find, by using the identity $A^2+B^2=\frac{1}{2}(A+B)^2+\frac{1}{2}(A-B)^2$, that

$$\Lambda \geqq \sum_{j=2}^{n-k-1}\{(\xi_{n-k}-\xi_j)^2+(\xi_j-\xi_1)^2\}+(\xi_{n-k}-\xi_1)^2 \geqq \frac{n-k}{2}\sigma^2 \tag{12}$$

with equality only if $2\xi_j=\xi_1+\xi_{n-k}$ for $2\leqq j\leqq n-k-1$. Therefore by (11) and (12)

$$\sigma^2 \leqq \frac{2(n-k)(n-k-1)}{n-1} \tag{13}$$

with equality only if

$$s_1=0, \quad \sum_{i=1}^{n} x_i^2 = n \quad \text{and} \quad 2\xi_j=\xi_1+\xi_{n-k} \quad \text{for } 2\leqq j\leqq n-k-1. \tag{14}$$

Now from (8) and (14)

$$\sum_{j=1}^{n-k}\xi_j = \frac{n-k}{2}(\xi_1+\xi_{n-k}) = 0,$$

so that $\xi_j=0$ for $2\leqq j\leqq n-k-1$, and $|\xi_1|=|\xi_{n-k}|$. Then from (13) we get

$$\xi_1^2 = \frac{(n-k-1)(n-k)}{2(n-1)},$$

so that the maximum span is attained when

$$P^{(k)}(x) = c_1x^{n-k-2}\left(x^2-\frac{(n-k-1)(n-k)}{2(n-1)}\right).$$

Integrating k times we get (6).

4. An analogous problem is to find the "minimum span" of the kth derivative of polynomials $P(x)$ having a given span. More precisely, consider the class π_n^* of polynomials of the form $(x^2-1)Q(x)$ where $Q(x)$ is of degree $n-2$ having all zeros in $[-1, 1]$. The problem is to determine

$$\min_{P\in\pi_n^*}\sigma(P^{(k)}).$$

For the special case $k=n-2$, the solution is easy to obtain from (10). Indeed in this case,

$$\Lambda = \sigma^2 = \frac{4}{n(n-1)}\left\{2 + \sum_{i=1}^{n-2} x_i^2 - \frac{1}{n}\left(\sum_{i=1}^{n-2} x_i\right)^2\right\} \geqq \frac{8}{n(n-1)}$$

with equality only if $x_i=0$ for $i=1, \cdots, n-2$ which follows from Schwarz's inequality. Therefore in this case

$$\min_{P\in\pi_n^*} \sigma(P^{(n-2)}) = 2\sqrt{\frac{2}{n(n-1)}}.$$

This minimum is attained for $P(x)=cx^{n-2}(x^2-1)$.

In the general case the problem seems to be more involved, but we conjecture that, for any k, the polynomial yielding the solution of the problem will be $cx^{n-2}(x^2-1)$.

Two more related problems can be formulated as follows in the notation already used:

PROBLEM I. Let $P(x)\in\pi_n$ satisfying either of the conditions:

$$\text{(i)}\ |x_i| \leqq 1, \qquad \text{(ii)}\ \frac{1}{n}\sum_1^n x_i \leqq 1,\quad x_i \geqq 0, \qquad \text{(iii)}\ \frac{1}{n}\sum_1^n x_i^2 \leqq 1.$$

To find the polynomial in the corresponding class which maximizes

$$\min_{2\leqq j\leqq n-k} |\xi_j - \xi_{j-1}|.$$

PROBLEM II. If $P(x)\in\pi_n^*$, find the polynomial which minimizes

$$\max_{2\leqq j\leqq n-k} |\xi_j - \xi_{j-1}|.$$

When $k=n-2$, Problem I is equivalent to maximizing the span under the different conditions. In case (i) this reduces to the result of Robinson [1, p. 507] and can be obtained directly from our formula (10), since in this case we have

$$\sigma^2 = \Lambda = \frac{4}{n(n-1)}\left\{\sum_1^n x_i^2 - \frac{1}{n}\left(\sum_1^n x_i\right)^2\right\}.$$

Obviously, when $|x_i| \leqq 1$, we have

$$\sigma(P^{(n-2)}) = \frac{2}{\sqrt{(n-1)}}, \quad \text{when } n \text{ is even}$$

$$= \frac{2\sqrt{(n+1)}}{n}, \quad \text{when } n \text{ is odd.}$$

The case (ii), (iii) of Problem I and Problem II are in this special case equivalent to the case $k=n-2$ of Theorems 1 and 2.

REPRESENTATION OF AN INTEGER AS A SUM OF FOUR INTEGER CUBES AND RELATED PROBLEMS

D. A. KLARNER, McMaster University

To my friend and teacher J. E. Householder

In 1936, L. J. Mordell [5] showed that integers belonging to all but 54 of the residue classes modulo 216 have at least one representation as a sum of four integer cubes; the proof is accomplished for a given r by writing an identity of the form

$$\sum_{i=1}^{4} (a_i k + b_i)^3 = 216k + r, \tag{1}$$

where k is a parameter and $a_1, a_2, \cdots, b_1, b_2, \cdots$ are certain integers depending on r. Sierpinski [7] seems to have been the first to conjecture that

$$k = x_1^3 + x_2^3 - x_3^3 - x_4^3 \tag{2}$$

has infinitely many solutions in nonnegative integers $x_1, x_2, \cdots$ for any given integer k and he and Schinzel [6] and Makowski [4] have proved the conjecture for all natural numbers $k \leqq 350$ except 148 and 284, as well as an infinite number of others.

It is known that every integer has infinitely many representations as a sum of five integer cubes; and considerations involving congruences reveal that numbers in the residue classes ± 4 modulo 9 cannot be the sum of three integer cubes; it has been conjectured that the numbers in the remaining classes do have such representations. The smallest number for which the conjecture is in doubt is 30; machine computations carried out by Gardiner, Lazarus and Stein [2] seem to indicate that numbers which have one representation as a sum of three integer cubes have many. It is an open question whether any number having one representation as a sum of three integer cubes has infinitely many. For example, Mordell has expressed interest in the equation

$$x_1^3 + x_2^3 + x_3^3 = 3 \tag{3}$$

for which only two essentially different solutions are known; viz., $1^3+1^3+1^3=3$ and $4^3+4^3-5^3=3$.

In this note we solve certain cubic Diophantine equations in binary quadratic forms; for example, we treat

$$x_1^3 + x_2^3 + x_3^3 + x_4^3 = kx_5^3, \tag{4}$$

with $k=a_1^3+a_2^3+a_3^3+a_4^3$, in order to prove a theorem due to Mordell [3] which plays a central role in the results of Sierpinski and Schinzel mentioned above. Solutions to (4) in binary quadratic forms when $k=0$ have been given already; for example, the identities

$$\begin{aligned}(3u^2 + 5uv - 5v^2)^3 + (4u^2 - 4uv + 6v^2)^3 + (5u^2 - 5uv - 3v^2)^3 \\ + (-6u^2 + 4uv - 4v^2)^3 = 0,\\ (6u^2 + 20uv - 56v^2)^3 + (u^2 - 7uv + 63v^2)^3 + (8u^2 - 20uv - 42v^2)^3 \\ + (-9u^2 + 7uv - 7v^2)^3 = 0,\\ (3u^2 + 16uv - 7v^2)^3 + (6u^2 - 4uv + 14v^2)^3 + (-6u^2 - 4uv - 14v^2)^3 \\ + (-3u^2 + 16uv + 7v^2)^3 = 0,\end{aligned}$$

were discovered by Ramanujan [3], Osborn, and Teilhet [1] respectively. Actually, writing $u+v$ and $u-v$ in place of u and v, respectively, in Ramanujan's identity gives Teilhet's identity, so one is just a linear transformation of the other.

To solve (4) we begin by seeking complex numbers b_1 and b_2 such that the matrix multiplication

$$\begin{bmatrix} a_1 & b_1 & a_2 \\ a_2 & -b_1 & a_1 \\ a_3 & b_2 & a_4 \\ a_4 & -b_2 & a_3 \\ 1 & 0 & 1 \end{bmatrix} \begin{bmatrix} u^2 \\ uv \\ v^2 \end{bmatrix} = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix} \tag{5}$$

defines forms $x_1, x_2, \cdots$ which satisfy (4). The 5×3 matrix in (5) is called a *coefficient matrix*, and multiplying this by the *parameter matrix* gives the *forms* $x_1, x_2, \cdots$. If $a_1, a_2, \cdots, b_1, b_2,$ are complex numbers such that (4) is an algebraic identity, we can make homogeneous linear substitutions $u\to\alpha_1 u+\beta_1 v$, $v\to\alpha_2 u+\beta_2 v$, where $\alpha_1, \cdots$ are complex numbers, and the relation in (4) remains an identity; only the coefficients of u^2, uv, and v^2 are changed. We say the new forms resulting from this substitution are *equivalent* to the originals, and that the corresponding new coefficient matrix is *equivalent* to the one we started with.

Equating the coefficients of u^6, u^5v, $\cdots$ in (5) gives only two equations which must be satisfied by b_1 and b_2; namely,

$$(a_1^2 - a_2^2)b_1 + (a_3^2 - a_4^2)b_2 = 0, \tag{6}$$

$$(a_1 + a_2)b_1^2 + (a_3 + a_4)b_2^2 = a_1^3 + a_2^3 + a_3^3 + a_4^3 - a_1a_2(a_1 + a_2) - a_3a_4(a_3 + a_4). \tag{7}$$

Solving this system for b_1 and b_2 gives

$$b_1 = (a_4^2 - a_3^2)h^{-1/2}, \qquad b_2 = (a_1^2 - a_2^2)h^{-1/2}, \tag{8}$$

where

$$h = (a_1 + a_2)(a_3 + a_4). \tag{9}$$

Substituting the expressions for b_1 and b_2 given in (8) into the coefficient matrix in (5) gives forms satisfying (4). Making the transformation $u \to u$, $v \to vh^{1/2}$ gives a coefficient matrix equivalent to the one just found but having the additional property that all of the elements are integers. Thus,

$$\begin{bmatrix} a_1 & a_4^2 - a_3^2 & a_2h \\ a_2 & a_3^2 - a_4^2 & a_1h \\ a_3 & a_1^2 - a_2^2 & a_4h \\ a_4 & a_2^2 - a_1^2 & a_3h \\ 1 & 0 & h \end{bmatrix} \begin{bmatrix} u^2 \\ uv \\ v^2 \end{bmatrix} = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix} \tag{10}$$

is a solution of (4) in binary quadratic forms; this solution can be used to find infinitely many solutions of (4) in integers provided $a_1 \neq \pm a_2$ and $a_3 \neq \pm a_4$, otherwise $h = 0$ and the forms in (10) become trivial. Furthermore, the Pellian equation

$$x_5 = u^2 + (a_1 + a_2)(a_3 + a_4)v^2 = 1 \tag{11}$$

has infinitely many solutions u, v provided only that $(a_1+a_2)(a_3+a_4)$ is the negative of a nonsquare number, so that we have given a new proof of Mordell's

THEOREM 1. *If $k = a_1^3+a_2^3+a_3^3+a_4^3$ with $-(a_1+a_2)(a_3+a_4)$ a nonsquare and $a_1 \neq a_2$, $a_3 \neq a_4$, then k has infinitely many representations as a sum of four integer cubes.*

Equation (4) is a special case of the more general equation

$$f(x_1, x_2) + f(x_3, x_4) = kx_5^3, \tag{12}$$

where $k = f(a_1, a_2) + f(a_3, a_4)$ and $f(x, y) = ax^3 + bx^2y + cxy^2 + dy^3$ is a given binary cubic form. We can solve (12) in the same way we solved (4), and this result leads in turn to a more general version of Theorem 1. This time we set

$$(13)\qquad \begin{bmatrix} a_1 & b_1 & a_3 \\ a_2 & b_2 & a_4 \\ a_3 & -b_1 & a_1 \\ a_4 & -b_2 & a_2 \\ 1 & 0 & 1 \end{bmatrix} \begin{bmatrix} u^2 \\ uv \\ v^2 \end{bmatrix} = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix}$$

and again find b_1 and b_2 in terms of $a_1, a_2, \cdots$ using the system of equations found by equating coefficients of like powers of u and v in (12); this system consists of just two equations, the other five are either identities or are equivalent to these:

$$(14)\qquad \{3a(a_1^2 - a_3^2) + 2b(a_1a_2 - a_3a_4) + c(a_2^2 - a_4^2)\}b_1 + \{3d(a_2^2 - a_4^2) + ac(a_1a_2 - a_3a_4) + b(a_1^2 - a_3^2)\}b_2 = 0,$$

$$(15)\qquad \{3a(a_1 + a_3) + b(a_2 + a_4)\}b_1^2 + \{2b(a_1 + a_2) + 2c(a_2 + a_4)\}b_1b_2 + \{3d(a_2 + a_4) + c(a_1 + a_3)\}b_2^2 + \{3a(a_1^2a_3 + a_3^2a_1) + b(a_1^2a_4 + a_3^2a_2 + 2a_1a_2a_3 + 2a_1a_3a_4) + c(a_2^2a_3 + a_4^2a_1 + 2a_1a_2a_4 + 2a_2a_3a_4) + 3d(a_2^2a_4 + a_4^2a_2)\} = 0.$$

Making obvious substitutions, we can abbreviate (14) and (15) by writing $K_1, K_2, \cdots$ for constants; thus,

$$(14')\qquad K_1b_1 + K_2b_2 = 0,$$

$$(15')\qquad K_3b_1^2 + K_4b_1b_2 + K_5b_2^2 + K_6 = 0.$$

Solving for b_1 and b_2 gives

$$(16)\qquad b_1 = -K_2(p/q)^{1/2}, \qquad b_2 = K_1(p/q)^{1/2}$$

where p and q are the numerator and denominator respectively of the reduced fraction

$$(17)\qquad -K_6/(K_3K_2^2 - K_1K_2K_4 + K_1^2K_5).$$

Substituting the values of b_1 and b_2 in (16) into the coefficient matrix in (13) and making the transformation $u \to u$, $v \to v(pq)^{1/2}$ gives a coefficient matrix having integral elements:

$$(18)\qquad \begin{bmatrix} a_1 & -K_2p & a_3pq \\ a_2 & K_1p & a_4pq \\ a_3 & K_2p & a_1pq \\ a_4 & -K_1p & a_2pq \\ 1 & 0 & pq \end{bmatrix} \begin{bmatrix} u^2 \\ uv \\ v^2 \end{bmatrix} = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix}.$$

The forms $x_1, \cdots$ defined by (18) satisfy (12) and if pq is the negative of a natural number which is not a square, $x_5 = u^2 + pqv^2$ is unity for infinitely many values of u and v, and hence

$$f(x_1, x_2) + f(x_3, x_4) = k \tag{19}$$

has infinitely many solutions in integers $x_1, x_2, \cdots$.

The fact that infinitely many integers k exist such that (19) has infinitely many solutions in integers $x_1, x_2, \cdots$ leads one to guess that under the right conditions every number should have such a representation. A. Schinzel in reading the first draft of this paper made the following comment: "Clearly, if $f(x, y) = ax^2 + bx^2y + cxy^2 + dy^3$ and (21) is to have a solution for every k we must have $(a, b, c, d) = 1$, but this is not sufficient for the solvability of the congruence

$$f(x_1, x_2) + f(x_3, x_4) \equiv k \pmod{m}$$

as shown by the example $f(x, y) = x^3 + 7y^3$, $k = 3$ and $m = 7$. It should not be difficult to prove that if the congruence is solvable modulo 7 and 9 and $(a, b, c, d) = 1$ then it is solvable for every modulus. (I have proved this for prime moduli.)"

When $k = 0$, (19) can be written

$$f(x_1, x_2) = f(x_3, x_4). \tag{20}$$

Here the problem is to find numbers which have two representations in a given binary cubic form $f(x, y) = ax^3 + bx^2y + cxy^2 + dy^3$. We note that if one solution, $f(a_1, a_2) = f(a_3, a_4)$ with $a_1 \neq a_3$, $a_2 \neq a_4$, of (20) is known, (18) can be used to find a solution of (20) in binary quadratic forms which in turn can be used to find infinitely many solutions in relatively prime integers. It may be of interest to see how far one can go in solving (20) in binary quadratic forms and to this end I have made an investigation of the special case

$$ax_1^3 + dx_2^3 = ax_3^3 + dx_4^3. \tag{21}$$

Starting with one solution $x_i = a_i$ of (21), a modified version of the coefficient matrix in (18) can be found which produces a solution in binary quadratic forms; thus the forms defined in

$$\begin{bmatrix} a_1 & (a_4^2 - a_2^2)dl^{-1/2} & a_3 \\ a_2 & (a_1^2 - a_3^2)al^{-1/2} & a_4 \\ a_3 & (a_4^2 - a_2^2)dl^{-1/2} & a_1 \\ a_4 & (a_1^2 - a_3^2)al^{-1/2} & a_2 \end{bmatrix} \begin{bmatrix} u^2 \\ uv \\ v^2 \end{bmatrix} = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} \tag{22}$$

where $l = -ad(a_1 - a_3)(a_2 - a_4)$, satisfy (21).

Making the transformation $u \to u + v$, $v \to u - v$, the coefficient matrix in (22) is seen to be equivalent to

$$(23)\qquad \begin{bmatrix} a_1+a_3+(a_4^2-a_2^2)dl^{-1/2} & 2(a_1-a_3) & a_1+a_3-(a_1^2-a_2^2)dl^{-1/2} \\ a_2+a_4+(a_1^2-a_3^2)al^{-1/2} & 2(a_2-a_4) & a_2+a_4-(a_1^2-a_3^2)al^{-1/2} \\ a_1+a_3+(a_4^2-a_2^2)dl^{-1/2} & -2(a_1-a_3) & a_1+a_3-(a_4^2-a_2^2)dl^{-1/2} \\ a_2+a_4+(a_1^2-a_3^2)al^{-1/2} & -2(a_2-a_1) & a_2+a_4-(a_1^2-a_3^2)al^{-1/2} \end{bmatrix}$$

which in turn has the form

$$(24)\qquad \begin{bmatrix} R(-f_1f_2ad)^{1/2}/af_1 & 2f_1 & -\overline{R}(-f_1f_2ad)^{1/2}/af_1 \\ R & 2f_2 & \overline{R} \\ -R(-f_1f_2ad)^{1/2}/af_1 & -2f_1 & -\overline{R}(-f_1f_2ad)^{1/2}/af_1 \\ R & -2f_2 & \overline{R} \end{bmatrix}$$

where R and its conjugate $\overline{R}$ are elements of the simple extension $K[(f_1f_2ad)^{-1/2}]$ of the field of rationals. We continue as before, equating the coefficients of u^6, u^5v, $\cdots$ after substituting the forms defined by (24) into the equation under discussion. The resulting system is relatively simple and the Diophantine problems can be solved by old methods. As an example, one can solve the system associated with (24) when the coefficient matrix has the special form

$$(25)\qquad \begin{bmatrix} A & 2C & A \\ B & 2D & -B \\ A & -2C & A \\ B & -2D & -B \end{bmatrix}$$

with A and B arbitrary integers and C and D to be determined in terms of A, B, a and d. The result after a transformation is

$$(26)\qquad \begin{bmatrix} A(aA^3+dB^3) & -6dAB^3 & 3A(aA^3-dB^3) \\ B(aA^3+dB^3) & 6aA^3B & -3B(aA^3-dB^3) \\ A(aA^3+dB^3) & 6dAB^3 & 3A(aA^3-dB^3) \\ B(aA^3+dB^3) & -6aA^3B & -3B(aA^3-dB^3) \end{bmatrix}.$$

The identity corresponding to this coefficient matrix can be used to prove that every rational number a/d has infinitely many representations in the form $(x_1^3+x_2^3)/(x_3^3+x_4^3)$ where the x's are binary quadratic forms or relatively prime integers.

A CHARACTERIZATION OF FINITE FIELDS

BROTHER JOSEPH HEISLER, C.S.C., St. Edward's University, Austin, Texas

Let R be a ring and let $f(x)\in R[x]$, say $f(x)=a_nx^n+\cdots+a_1x+a_0$. By the left functional value of $f(x)$ at $b\in R$ I shall mean $a_nb^n+\cdots+a_1b+a_0$, which will be denoted by $f_L(b)$.

If R is a ring and f is a mapping of R into R, then f is said to be left represented by a polynomial if there exists an $\bar{f}(x)\in R[x]$ such that $f(r)=\bar{f}_L(r)$ for each $r\in R$.

The purpose of this paper is to establish the following characterization of finite fields: if R is a nonzero ring then R is a finite field if and only if each function f mapping R into R is left represented by a polynomial.

If k is a finite integral domain, and so a finite field, then each function f mapping k into k is a polynomial function. This is no longer true if k is a finite ring with zero divisors. Consider for example the ring Z_4 of rational integers modulo 4 and the function $f: Z_4\to Z_4$ where $f(3)=1$ and $f(r)=0$ for $r=0, 1, 2$. Suppose that there exist elements a_i in Z_4 such that $f(x)=a_0+a_1x+\cdots+a_sx^s$ for each x in Z_4. Since $x^2(x^2-1)=0$ for each x in Z_4 we may assume that $s<4$. Specializing, we get

$$f(0) = a_0 = 0,$$

$$f(1) = a_1 + a_2 + a_3 = 0, \tag{1}$$

$$f(2) = 2a_1 = 0, \tag{2}$$

$$f(3) = 3a_1 + a_2 + 3a_3 = 1. \tag{3}$$

Equation (2) implies that $a_1=0$ or 2. This, (1), and (3) imply that $2a_3=1$, which is not solvable in Z_4.

In the above example, the ring R had zero divisors, but if R is a ring with unity such that each function mapping R into R is left represented by a polynomial, then R must be a division ring. The following theorem establishes this and more.

THEOREM 1. *Let R be a ring with unity and let R^* denote the group of units of R. Suppose that there exist a function f mapping R into R and an $\bar{f}(x)\in R[x]$ such*

that $f(0)=\bar{f}_L(0)=0$ *and* $f(r)=\bar{f}_L(r)$ *is in* R^* *for* $r\neq 0$ *and* $r\in(R-R^*)$. *Then* R *is a division ring.*

Proof. Suppose that $f(r)=a_0+a_1r+\cdots+a_mr^m$ for each $r\in(R-R^*)$. Then $f(0)=0$ implies that $a_0=0$. For $r\in(R-R^*)$ and $r\neq 0$, $f(r)=a_1r+\cdots+a_mr^m=(a_1+\cdots+a_mr^{m-1})r=u(r)$ is in R^*. Thus $(u(r))^{-1}(a_1+\cdots+a_mr^{m-1})r=1$. Hence, each nonzero element of $R-R^*$ has a left inverse. Since elements of R^* have left inverses we see that each nonzero element of R has a left inverse in R. It is now an elementary exercise to show that the nonzero elements of R form a group with respect to multiplication.

We note that each finite ring satisfying the hypotheses of Theorem 1 must be a field. A ring satisfying the hypotheses of Theorem 1 will not generally be a field. For example, the quaternions over the reals with $f(x)=x$ is such a ring. We also note that the requirement that the function f of the hypotheses be left representable on $(R-R^*)$ by a polynomial is necessary. For example, let R be the rational integers, so that $R^*=\{-1, 1\}$. Then R is not a division ring but the function $f: R\to R$ such that $f(x)=0$ for $x\in R^*$ or $x=0$, and $f(x)=1$ otherwise, satisfies the hypotheses of the theorem other than being left represented on $(R-R^*)$ by a polynomial.

For the rest of this paper we assume that R is a nonzero ring such that each function f mapping R into R is left represented by a polynomial. Then R is a finite ring. We now show that R has no zero divisors. To see this, suppose that there exist elements u and v in R, $u\neq 0$ and $v\neq 0$, such that $uv=0$. Let f be a function mapping R into R such that $f(0)=0$ and $f(u)=v$. Then there is a polynomial $\bar{f}(x)=a_mx^m+\cdots+a_1x$ in $R[x]$ such that $f(r)=\bar{f}_L(r)$ for each $r\in R$. Then $f(u)=(a_mu^{m-1}+\cdots+a_1)u=\bar{g}(u)u=v$. Hence, $0=\bar{g}(u)uv=f(u)v=v^2$ and $f(v)=\bar{g}(v)v$, and so $f(v)v=\bar{g}(v)v^2=0$. Since there are functions f such that $f(0)=0$ and $f(u)=v$, with $f(v)$ arbitrary in R, we must have that $Rv=0$. In particular, there are such f with $f(v)\neq 0$, contrary to the fact that $f(v)=\bar{g}(v)v$ which is in $Rv=0$. Thus R can have no zero divisors.

In summary, if R is a nonzero ring such that each function mapping R into R is left represented by a polynomial, then R is finite, has no zero divisors, and so is a finite field. Thus we have

THEOREM 2. *If* R *is a nonzero ring, then* R *is a finite field if and only if each function mapping* R *into* R *is left represented by a polynomial.*

Or he too simplified.

MARLOW SHOLANDER

MATHEMATICAL NOTES

SETS OF NUMBERS DEFINED BY FINITE AUTOMATA

J. HARTMANIS, Cornell University and R. E. STEARNS, G.E. Research Laboratory

1. Introduction. In this note we investigate the topological properties of sets of real numbers defined by finite automata. The concept of an automaton "defining" a number is obtained through a natural extension of the concept of an automaton accepting a finite sequence. Under this definition, we show that a finite automaton defines a closed set of numbers, we characterize those automata whose defined sets contain nontrivial intervals, and show that the end points of these intervals are rational numbers. Furthermore, we show that the measure of a set defined by an automaton is always rational.

2. Automata and defined sets. A *finite automaton* M is a quintuplet

$$M = (S, I, \delta, s_0, T),$$

where S and I are the finite nonempty sets of states and inputs,

$$\delta: \quad S \times I \rightarrow S$$

is the next state function, s_0 is the starting state and $T \subseteq S$ is the set of terminal states.

An input sequence

$$\bar{x} = x_1 x_2 \cdots x_n, \qquad x_i \text{ in } I,$$

is *accepted* by M if and only if it transfers s_0 to a terminal state, which we write symbolically as $\bar{\delta}(s_0, \bar{x}) \in T$, where $\bar{\delta}$ is the natural extension of δ to input sequences. The set of sequences accepted by M is denoted by R_M. Two states s and t of an automaton $M = (S, I, \delta, s_0, T)$ are said to be *equivalent* if and only if the automata

$$M' = (S, I, \delta, s, T) \quad \text{and} \quad M'' = (S, I, \delta, t, T)$$

accept the same set of sequences, $R_{M'} = R_{M''}$. An automaton is *reduced* if and only if no two distinct states are equivalent and all its states can be reached from the starting state. A more detailed discussion of finite automata can be found in [1].

DEFINITION 1. *Let r be an integer greater than 1 and let M be a finite automaton whose set I of inputs is the set of digits used in representing numbers in radix r notation. A real number α between 0 and 1 is said to be defined by M if and only if α has at least one representation $\alpha = \cdot\alpha_1\alpha_2 \cdots \alpha_n \cdots$ in radix r notation such that for each integer $n \geqq 1$ the prefix $\alpha_1\alpha_2 \cdots \alpha_n$ is accepted by M. The set of numbers defined by M is denoted by D_M.*

DEFINITION 2. *An automaton M is a prefix acceptor if and only if*

$$\bar{x}\bar{y} \text{ in } R_M \text{ implies that } \bar{x} \text{ is in } R_M.$$

We say that a state s of M is a trapping state if and only if for all x in I, $\delta(s, x) = s$.

We now derive some properties of prefix acceptors.

LEMMA 1. *A reduced automaton M is a prefix acceptor if and only if there is at most one nonterminal state and the nonterminal state is a trapping state.*

Proof. If M satisfies the hypotheses, then it is a prefix acceptor since once a sequence $\bar{x}$ is not accepted, all its continuations $\bar{x}\bar{y}$ are also not accepted. To prove the converse, let M be a reduced prefix acceptor. The states in $S-T$ must all be equivalent since all input sequences must transform them to nonterminals. Therefore, since M is reduced, $S-T$ can contain at most one state which can only be transformed into itself.

LEMMA 2. *A reduced prefix acceptor, M, defines a set which contains a nontrivial interval if and only if it has a trapping terminal state.*

Proof. We assume without loss of generality that $I = \{0, 1\}$. If the defined set contains an interval, then for some sequence $\bar{x} = x_1x_2 \cdots x_n$, the interval contains all α such that

$$\cdot x_1x_2 \cdots x_n0 \leqq \alpha \leqq \cdot x_1x_2 \cdots x_n1.$$

It follows that, for all finite sequences $\bar{y}$, the sequence

$$x_1x_2 \cdots x_n0\bar{y}$$

is accepted by M. Since M is reduced, there can be at most one state from which all continuations are accepted and the state

$$\bar{\delta}(s_0, x_1 \cdots x_n0) = s$$

must therefore be a trapping terminal state. Conversely, if M has a trapping terminal state, s, and

$$\bar{\delta}(s_0, \bar{x}) = s,$$

then for all $\bar{y}$, $\bar{\delta}(s_0, \bar{x}\bar{y}) = s$. But then all the α in the interval $\cdot\bar{x} \leqq \alpha \leqq \cdot\bar{x}1$ are defined by M and D_M contains a nontrivial interval.

THEOREM 1. *A prefix acceptor defines a closed set.*

Proof. We will prove that the complement of D_M is an open set. For simplicity we assume that $I = \{0, 1\}$. Let α be a point of the complement of D_M. We may speak of the left (lexicographically first) and of the right (lexicographically last) representation of α in radix r notation; these coincide in the case where α has only one representation. There exist prefixes $\bar{x}$ and $\bar{y}$ of the left and right representations, respectively, such that neither $\bar{x}$ nor $\bar{y}$ is accepted by M and we have

$$\cdot\bar{x}000 \cdots < \alpha < \cdot\bar{y}111 \cdots.$$

If

$$\cdot\bar{x}000\cdots < \beta < \cdot\bar{y}111\cdots,$$

then every representation of β has one of the sequences $\bar{x}$ and $\bar{y}$ as a prefix, and hence β is not accepted by M. This shows that the complement of D_M contains an open interval about α.

THEOREM 2. *The end points of a maximal interval contained in D_M are rational.* (The main result of [2] is a corollary of this theorem.)

Proof. We assume without loss of generality that $I = \{0, 1\}$. Let $\alpha = \cdot\alpha_1\alpha_2\alpha_3\cdots$ be the upper end point of a maximal interval in D_M. Then for some n, the interval contains the set of points

$$\{\beta \mid \cdot\alpha_1\alpha_2\cdots\alpha_n \leqq \beta \leqq \alpha\}.$$

First suppose that $\bar{\delta}(s_0, \alpha_1\alpha_2\cdots\alpha_p)$ is a trapping terminal state for some p. Then the rational number $\alpha' = \cdot\alpha_1\alpha_2\cdots\alpha_p 1\,1\,1\cdots$ must be in the interval and must be therefore the end point α since no larger value is possible.

Next assume that no prefix of α leads to a trapping terminal state. In this case, for all $p, q \geqq n$,

$$\bar{\delta}(s_0, \alpha_1\alpha_2\cdots\alpha_{p-1}) = \bar{\delta}(s_0, \alpha_1\alpha_2\cdots\alpha_{q-1})$$

must imply that $\alpha_p = \alpha_q$ because $\alpha_p = 1$ and $\alpha_q = 0$ would imply that, contrary to our hypothesis,

$$\bar{\delta}(s_0, \alpha_1\alpha_2\cdots\alpha_{p-1}0) = \bar{\delta}(s_0, \alpha_1\alpha_2\cdots\alpha_{q-1}\alpha_q)$$

is a trapping terminal because all continuations of $\alpha_1\alpha_2\cdots\alpha_{p-1}0$ must be accepted. Thus, for $m > n$, the value of α_m is determined by the state

$$s = \bar{\delta}(s_0, \alpha_1\alpha_2\cdots\alpha_{m-1})$$

and this in turn determines the next state $\delta(s, \alpha_m)$. Since there are only a finite number of states, the state sequence and the α_m must be periodic and α must be rational.

A very similar proof shows that the lower end point is rational.

We now state a result which is used to show that the measure of a set defined by a finite automaton is rational.

LEMMA 3. *Let C be a directed graph with rational transition probabilities, a starting node and a trapping node. Then the probability that the trapping node is entered is a rational number.* (This result can also be obtained from Markov Theory.)

Proof. (Outline) The proof can be done by induction on the number of nontrapping nodes.

(1) Clearly the result is true if there is only one nontrapping node.

(2) If there are $k+1$ nontrapping nodes, a new k node graph can be constructed from it which has the same probability in falling into the trapping node. This is done by removing a nontrapping, non-starting node and rerouting the arrows to perform "double node changes" with the appropriate new (rational) probabilities. Some of these "double node changes," owing to the possibility that there are immediate transitions from a node to itself, must consist of an infinite set of finite length sequences. In such a case the rational transition probability is obtained by summing a geometric series.

THEOREM 3. *The measure of a set defined by a finite automaton is rational.*

Proof. Let M be a reduced machine and again assume that $I=\{0, 1\}$. If equal probabilities are assigned to inputs, then the measure of the complement of D_M is seen to be the probability that s_0 goes into the nonterminal trapping state. This is because each sequence $\alpha_1\alpha_2 \cdots \alpha_n$ that transforms s_0 for the first time into the trapping nonterminal state must correspond to an interval of length 2^{-n} in the complement of D_M and the probability that this input sequence occurs is also 2^{-n}. By the previous lemma we know that this probability of entering the trapping nonterminal state is rational, and thus the measure of the complement of D_M is rational, and therefore the measure of D_M is rational.

For a given rational α, the set of numbers less than or equal to α can be defined by an automaton and has measure α. Thus measures are achieved for all rationals. Some interesting sets with measure zero can also be defined. For example, the Cantor middle-third set can be defined by a two-state automaton.

ON SCHWARZ DIFFERENTIABILITY—V

S. N. MUKHOPADHYAY, Burdwan University, India

Let $f(x)$ be a real function of the real variable x defined in an open interval I of which $[a, b]$ is a closed subinterval. For $x\in[a, b]$, if the limit

$$\operatorname*{Lt}_{h\to 0} \frac{f(x+h)-f(x-h)}{2h}$$

exists, it is called the Schwarz derivative [5] or the symmetric derivative [1] of $f(x)$ at the point x and is denoted by $f^{(1)}(x)$. It is clear that if the ordinary derivative $f'(x)$ exists, then $f^{(1)}(x)$ also exists and $f^{(1)}(x)=f'(x)$; but the converse is not true.

In an interesting paper [6] Weinstock has shown that if $f(x)$ is differentiable in I, then a necessary and sufficient condition that $f'(x)$ be continuous in $[a, b]$

is that $f(x)$ should be uniformly differentiable in $[a, b]$. The purpose of the present note is to prove a result on Schwarz derivative (Theorem 1) and to study whether Weinstock's result remains true if one replaces ordinary derivative by Schwarz derivative.

We have introduced the following definition in [2] and also utilized it in [3].

DEFINITION. *Let $f(x)$ be Schwarz differentiable at each point x of I and suppose that*

$$\psi(x, h) = \frac{f(x+h) - f(x-h)}{2h} - f^{(1)}(x).$$

Then $f(x)$ is said to be uniformly Schwarz differentiable in $[a, b]$, if corresponding to the arbitrary $\epsilon > 0$, there exists a $\delta > 0$ (independent of x) such that $|\psi(x, h)| < \epsilon$, if $|h| < \delta$ for $x \in [a, b]$ and $x \pm h \in I$.

In earlier papers, the following results have been proved.

A. If $f(x)$ is continuous and uniformly Schwarz differentiable in I then $f^{(1)}(x)$ is continuous in $[a, b]$ (corollary 2, Theorem 9 [2]).

B. Let $f(x)$ be continuous and Schwarz differentiable in an open interval I of which $[a, b]$ is a closed subinterval. If $f^{(1)}(x)$ is nonnegative almost everywhere in $[a, b]$ then $f(x)$ is nondecreasing in $[a, b]$ (Theorem 3 [4]).

As a consequence of the result B, we obtain the following:

COROLLARY. *Let $f(x)$ be continuous and Schwarz differentiable in an open interval I of which $[a, b]$ is a closed subinterval. If $f^{(1)}(x) = 0$ almost everywhere in $[a, b]$, then $f(x)$ is constant in $[a, b]$.*

The result A gives the sufficient part of the analogue. Theorem 2 here contains the necessary part.

THEOREM 1. *If $f(x)$ is uniformly Schwarz differentiable in I then*
(α) $f(x)$ is continuous in $[a, b]$ if $f^{(1)}(x)$ is bounded in $[a, b]$.
(β) $f^{(1)}(x)$ is bounded in $[a, b]$ if $f(x)$ is continuous in I.

Proof of (α). Assume, if possible, that $f(x)$ is discontinuous at $\xi \in [a, b]$; then there exists $\eta > 0$ such that for each $\delta > 0$, there are points x' in $[a, b] \cap (\xi - \delta, \xi + \delta)$ such that $|f(x') - f(\xi)| > \eta$.

Since $f^{(1)}(x)$ is bounded, there exists $M > 0$ such that $|f^{(1)}(x)| \leqq M$, $x \in [a, b]$. So,

$$\left|\psi\left(\frac{x' + \xi}{2}, \frac{x' - \xi}{2}\right)\right| = \left|\frac{f(x') - f(\xi)}{x' - \xi} - f^{(1)}\left(\frac{x' + \xi}{2}\right)\right| \geqq \frac{\eta}{|x' - \xi|} - M.$$

Since x' can be chosen sufficiently near to ξ, this contradicts the hypothesis that $f(x)$ is uniformly Schwarz differentiable in I.

Proof of (β). By the result A, it follows that $f^{(1)}(x)$ is continuous in $[a, b]$. So, (β) holds.

REMARK. If $f(x)$ is uniformly Schwarz differentiable in $[a, b]$ then whether $f(x)$ may have points of discontinuity, remains an open question. The author, at the present stage, is unable to answer this. It is, however, highly possible that uniform Schwarz differentiability of $f(x)$ will imply continuity.

THEOREM 2. *If $f(x)$ and $f^{(1)}(x)$ are continuous in I then $f(x)$ is uniformly Schwarz differentiable in $[a, b]$.*

Proof. Let $\phi(x) = f(x) - \int_a^x f^{(1)}(t)dt$, $x \in I$. Then $\phi(x)$ is continuous and Schwarz differentiable in I and $\phi^{(1)}(x) = f^{(1)}(x) - f^{(1)}(x) = 0$ for $a \leqq x \leqq b$. Hence by corollary of the result B, $\phi(x) = c$, a constant, i.e.

$$f(x) = c + \int_a^x f^{(1)}(t)dt, \quad a \leqq x \leqq b.$$

Now

$$\begin{aligned} |\psi(x, h)| &= \left| \frac{1}{2h} \int_{x-h}^{x+h} f^{(1)}(t)dt - f^{(1)}(x) \right| \\ &= |f^{(1)}(x + \theta h) - f^{(1)}(x)|, \quad -1 \leqq \theta \leqq 1. \end{aligned}$$

Since $f^{(1)}(x)$ is continuous and so uniformly continuous in $[a, b]$, corresponding to arbitrary $\epsilon > 0$, there is a $\delta > 0$ (independent of x) such that

$$|f^{(1)}(x + h) - f^{(1)}(x)| < \epsilon, \quad \text{whenever } |h| < \delta.$$

So, from the above, we get $|\psi(x, h)| < \epsilon$, whenever $|h| < \delta$ and $x \in [a, b]$.

Note. The continuity of $f(x)$ is necessary. For, consider the function defined as

$$f(x) \begin{cases} = 0 & \text{if } x \neq 0 \\ = 1 & \text{if } x = 0. \end{cases}$$

Here $f^{(1)}(x)$ is continuous everywhere but $f(x)$ is not uniformly Schwarz differentiable in any interval including $x = 0$.

I am thankful to Dr. B. K. Lahiri for his kind help and suggestions in the preparation of the paper.

SOME SPECIAL INTEGRALS

JYOTI CHAUDHURI, Jadavpur University, Calcutta, India

In 1957 Bremekamp [3] proposed the problem of showing that

$$\int_0^{\pi} (\log \sin\theta)^2 d\theta = \frac{\pi^3}{12} + \pi(\log 2)^2. \tag{1}$$

It has been solved by Beumer [1] in 1961, who has generalized it by giving the value of $\int_0^{\pi/2} (\log \sin\theta)^n d\theta$ as a Dirichlet series. In 1947 F. Bowman [2] gave the value of this integral as

$$(-1)^n \tfrac{1}{2}\pi \begin{vmatrix} \sigma_1 & -1 & 0 & 0 & \cdots & 0 \\ \sigma_2 & \sigma_1 & -2 & 0 & \cdots & 0 \\ \sigma_3 & \sigma_2 & \sigma_1 & -3 & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ \sigma_{n-1} & \sigma_{n-2} & \sigma_{n-3} & \sigma_{n-4} & \cdots & -(n-1) \\ \sigma_n & \sigma_{n-1} & \sigma_{n-2} & \sigma_{n-3} & \cdots & \sigma_1 \end{vmatrix} \tag{2}$$

where

$$\sigma_r = \frac{1}{1^r} - \frac{1}{2^r} + \frac{1}{3^r} - \frac{1}{4^r} + \cdots.$$

The object of this note is to obtain the value of a more general type of integral

$$\int_0^{\pi/2} (\log \sin^p\theta \cos^q\theta)^n d\theta, \tag{3}$$

where n is a nonnegative integer and p, q are any two positive rational numbers.

Let us write

$$D(n) = \frac{(-1)^{n-1}}{(n-1)!} \int_0^{\pi/2} (\log \sin^p\theta \cos^q\theta)^{n-1} d\theta. \tag{A}$$

Now since

$$\sum_{n=0}^{\infty} \frac{(\log \sin^p\theta \cos^q\theta)^n x^n}{n!} = \sin^{px}\theta \cos^{qx}\theta,$$

so that the series is uniformly convergent in $0<\theta<\pi/2$, term by term integration is valid. Hence

$$\sum_{n=0}^{\infty} \frac{x^n}{n!} \int_0^{\pi/2} (\log \sin^p\theta \cos^q\theta)^n d\theta = \int_0^{\pi/2} \sin^{px}\theta \cos^{qx}\theta d\theta$$

or,

$$\sum_{n=0}^{\infty}(-1)^n x^n D(n+1)=\frac{1}{2}\frac{\Gamma((px+1)/2)\Gamma((qx+1)/2)}{\Gamma((px+qx+2)/2)}. \tag{4}$$

Similarly,

$$\sum_{n=0}^{\infty}D(n+1)x^n=\int_0^{\pi/2}(\sin^p\theta\cos^q\theta)^{-x}d\theta$$

$$=\frac{1}{2}\frac{\Gamma((1-px)/2)\Gamma((1-qx)/2)}{\Gamma(1-(px+qx)/2)} \tag{5}$$

$$=\frac{\pi}{2}\frac{\sin((p+q)x\pi)/2)}{\sin((1+px)/2)\pi\sin((1+qx)/2)\pi}\frac{\Gamma((px+qx)/2)}{\Gamma((1+px)/2)\Gamma((1+qx)/2)}.$$

Due to uniform convergence, direct multiplication of (4) and (5) is justified, and hence we get

$$\left\{\sum_{n=0}^{\infty}(-1)^n D(n+1)x^n\right\}\left\{\sum_{n=0}^{\infty}D(n+1)x^n\right\}$$

$$=\frac{\pi}{2(p+q)x}\frac{\sin[(p+q)x\pi/2]}{\cos px\pi/2\cos qx\pi/2}$$

$$=\frac{\pi}{2(p+q)x}\{\tan px\pi/2+\tan qx\pi/2\}.$$

But we know ([4], p. 499) that

$$\tan\frac{\pi x}{2}=2\sum_{n=1}^{\infty}\frac{2^{2n}-1}{(2n)!}B_n\pi^{2n-1}x^n,$$

where B_n denotes the Bernoulli's numbers. Hence

$$\left\{\sum_{n=0}^{\infty}(-1)^n D(n+1)x\right\}\left\{\sum_{n=0}^{\infty}D(n+1)x^n\right\}$$

$$=\frac{\pi^2}{p+q}\sum_{n=1}^{\infty}\frac{2^{2n}-1}{(2n)!}B_n(\pi x)^{2n-2}(p^{2n-1}+q^{2n-1}). \tag{6}$$

Comparing coefficients of x^{2n-2} from both sides we have

$$D(1)D(2n-1)-D(2)D(2n-2)+\cdots+D(2n-1)D(1)$$

$$=\frac{2^{2n}-1}{(2n)!}B_n\pi^{2n}\frac{p^{2n-1}+q^{2n-1}}{p+q}. \tag{7}$$

Equating the constant term from both sides of (6)

$$\{D(1)\}^2 = \frac{\pi^2}{p+q}\,\frac{3}{2}\,B_1(p+q) = \frac{\pi^2}{4},$$

whence $D(1)=\pi/2$ as can also be seen from (A). Putting $n=2$ in (7), we obtain

$$D(1)D(3) - D(2)D(2) + D(3)D(1) = \frac{15}{4!}\,B_2\pi^4\frac{p^3+q^3}{p+q} = \frac{\pi^4}{48}(p^2 - pq + q^2).$$

From (A), $D(2) = -\int_0^{\pi/2}(\log \sin^p\theta \cos^q\theta)d\theta = (p+q)(\pi/2)\log 2$. Hence, $D(3) = (\pi/4)(p+q)^2(\log 2)^2 + (\pi^3/48)(p^2-pq+q^2)$ and so on. Writing $y = \sum_{n=0}^{\infty}(-1)^n x^n D(n+1)$, by logarithmic differentiation of (4) we get

$$\frac{1}{y}\frac{dy}{dx} = \frac{p}{2}\,\frac{\Gamma'((1+px)/2)}{\Gamma((1+px)/2)} + \frac{q}{2}\,\frac{\Gamma'((1+qx)/2)}{\Gamma((1+qx)/2)} - \frac{p+q}{2}\,\frac{\Gamma'((px+qx+2)/2)}{\Gamma((px+qx+2)/2)}.$$

But for $\mathrm{Re}(z)>0$,

$$\frac{\Gamma'(z)}{\Gamma(z)} = -\frac{1}{z} + \sum_{m=1}^{\infty}\left\{\log\left(1+\frac{1}{m}\right) - \frac{1}{m+z}\right\}.$$

Hence, expanding the right hand side accordingly we obtain

$$\begin{aligned}\frac{1}{y}\frac{dy}{dx} = {} & \frac{p}{2}\left[-\frac{2}{1+px} + \sum_{m=1}^{\infty}\log\left(1+\frac{1}{m}\right) - \sum_{m=1}^{\infty}\frac{1}{m+((1+px)/2)}\right] \\ & + \frac{q}{2}\left[-\frac{2}{1+qx} + \sum_{m=1}^{\infty}\log\left(1+\frac{1}{m}\right) - \sum_{m=1}^{\infty}\frac{1}{m+((1+qx)/2)}\right] \\ & - \frac{p+q}{2}\left[-\frac{2}{px+qx+2} + \sum_{m=1}^{\infty}\log\left(1+\frac{1}{m}\right)\right. \\ & \left. - \sum_{m=1}^{\infty}\frac{1}{m+1+((p+q)/2)x}\right].\end{aligned}$$

$$\frac{1}{y}\frac{dy}{dx} = \sum(-1)^{r+1}t_{r+1}x^r,$$

where

$$t_r = \sum_{m=1}^{\infty}\frac{(p^r+q^r)}{(2m+1)^r} - \sum_{m=0}^{\infty}\frac{(p+q)^r}{(2m+2)^r}.$$

Therefore,

$$\sum_{n=0}^{\infty}(-1)^n x^{n-1} n D(n+1) = \left\{\sum_{r=0}^{\infty}(-1)^{r+1}t_{r+1}x^r\right\}\cdot\left\{\sum_{n=0}^{\infty}(-1)^n D(n+1)x^n\right\}$$

whence, equating coefficients of x^{n-1}, we obtain

$$nD(n+1) = t_1D(n) + t_2D(n-1) + \cdots + t_{n-1}D(2) + t_nD(1). \tag{8}$$

It is now easy to deduce from (8) by the method of induction the general expression for $D(n+1)$ as given below:

$$(-1)^n \int (\log \sin^p \theta \cos^q \theta)^n d\theta = n!D(n+1)$$

$$= \frac{\pi}{2} \begin{vmatrix} t_1 & -1 & 0 & 0 & \cdots & 0 \\ t_2 & t_1 & -2 & 0 & \cdots & 0 \\ t_3 & t_2 & t_1 & -3 & \cdots & 0 \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\ t_{n-1} & t_{n-2} & t_{n-3} & t_{n-4} & \cdots & -(n-1) \\ t_n & t_{n-1} & t_{n-2} & t_{n-3} & \cdots & t_1 \end{vmatrix}.$$

The result (2) is easily obtained from (9) by putting $p=1$, $q=0$ because, in that case

$$t_r = \sum_{m=0}^{\infty} \frac{1}{(2m+1)^r} - \sum_{m=0}^{\infty} \frac{1}{(2m+2)^r} = \left(1 - \frac{1}{2^{r-1}}\right)\zeta(r) = \sigma_r, \tag{10}$$

where $\zeta(r)$ denotes the zeta function of Riemann. All the results of Beumer now follow from the above by substituting $p=1$, $q=0$.

I wish to express my indebtedness to Prof. B. N. Mukherjee for his help and guidance in the preparation of this paper.

LINEAR COMPLETELY INTEGRABLE PARTIAL DIFFERENTIAL EQUATIONS

H. H. JOHNSON, University of Washington

1. Introduction. The theory of linear ordinary differential equations [3, p. 69] illustrates how a problem in analysis can sometimes be simplified by algebraic methods. We study here an extension of this method to systems of partial differential equations which behave very much like ordinary differential equations. In particular, they have unique solutions for initial values of the variables.

Let $y^1, \cdots, y^n$ be coordinates in R^n, real Euclidean n-space, and let $x^1, \cdots,$

x^p be coordinates in R^p. We wish to study equations of the type

$$\frac{\partial y^i}{\partial x^\alpha} = f_\alpha^i(x^1, \cdots, x^p, y^1, \cdots, y^n), \qquad \begin{matrix} i = 1, \cdots, n \\ \alpha = 1, \cdots, p. \end{matrix}$$

Suppose a solution $y^i = y^i(x^1, \cdots, x^p)$, $i = 1, \cdots, n$ having continuous second partial derivatives exists passing through arbitrary points of $R^n \times R^p$. Then by the equality of the mixed partial derivatives $(\partial^2 y^i/\partial x^\alpha \partial x^\beta) = (\partial^2 y^i/\partial x^\beta \partial x^\alpha)$ and the chain rule, one must have

$$\frac{\partial f_\alpha^i}{\partial x^\beta} + \sum_{j=1}^n \frac{\partial f_\alpha^i}{\partial x^j} f_\beta^j = \frac{\partial f_\beta^i}{\partial x^\alpha} + \sum_{j=1}^n \frac{\partial f_\beta^i}{\partial y^j} f_\alpha^j \tag{1}$$

for all values of $y^1, \cdots, y^n, x^1, \cdots, x^p$. It is known that this necessary condition is also sufficient when the f_α^i have continuous second partial derivatives, and then there is a unique solution through each initial point (x_0^α, y_0^i) [1, p. 29]. See also [2, p. 104].

2. Linear completely integrable systems. Consider systems

$$\frac{\partial y^i}{\partial x^\alpha} = \sum_{j=1}^n A_{\alpha j}^i y^j, \qquad \begin{matrix} i = 1, \cdots, n, \\ \alpha = 1, \cdots, p, \end{matrix} \tag{2}$$

where $A_{\alpha j}^i \in R$ (real numbers). As in the case of ordinary differential equations we first consider how (2) behaves when we change the variables y or x by linear transformations. If $x^\alpha = \sum C_\beta^\alpha \bar{x}^\beta$, then

$$\frac{\partial y^i}{\partial x^\alpha} = \sum_{j=1}^n \sum_{\beta=1}^p A_{\beta j}^i C_\alpha^\beta y^j.$$

If $\bar{y}^i = \sum a_j^i y^j$, and $y^j = \sum b_i^j \bar{y}^i$, then

$$\frac{\partial \bar{y}^i}{\partial x^\alpha} = \sum_{j=1}^n \sum_{k=1}^n \sum_{l=1}^n a_j^i A_{\alpha k}^j b_l^k \bar{y}^l.$$

Thus, if we denote by A_α the $n \times n$ matrices $(A_{\alpha j}^i)$, and consider the vector space $L \subset R^{n^2}$ generated by these matrices, then a change of basis in R^p corresponds to a change of basis in L. A change of basis in R^n corresponds to a simultaneous similarity transformation $BA_\alpha B^{-1}$ of the elements of L. Thus, we may regard L as a vector space of linear transformations of R^n into R^n.

Next, the conditions (1) become

$$\sum_{j=1}^n A_{\alpha j}^i A_{\beta k}^j = \sum_{j=1}^n A_{\beta j}^i A_{\alpha k}^j,$$

for $i, j = 1, \cdots, n$; $\alpha, \beta = 1, \cdots, p$. This condition is recognized as merely $A_\alpha A_\beta = A_\beta A_\alpha$, that is, the elements of L *commute*. The algebraic problem is now

to study a vector space of commuting linear transformations on R^n. The general problem of classifying all such spaces remains open. In case one of the linear transformations in L has distinct eigenvalues, however, more can be said.

THEOREM 1. *Let L be a vector space of commuting linear transformations on R^n which contains a transformation having distinct eigenvalues. Then it is possible to choose a basis of R^n so that the matrices which represent elements of L are all diagonal matrices.*

Proof. Let $A \in L$ have distinct eigenvalues $\lambda_1, \cdots, \lambda_n$ and corresponding eigenvectors $Y_1, \cdots, Y_n$ (which are linearly independent).

If $A' \in L$, $A'(Y_j) = \sum C_j^k Y_k$, so that

$$AA'(Y_j) = \sum_{k=1}^{n} C_j^k \lambda_k Y_k,$$

$$A'A(Y_j) = \sum_{k=1}^{n} \lambda_j C_j^k Y_k.$$

Hence $(\lambda_k - \lambda_j) C_j^k = 0$ for $j, k = 1, \cdots, n$. Since the λ_j are distinct, $C_j^k = 0$ when $k \neq j$. Thus, A' is a diagonal matrix with respect to the basis $Y_1, \cdots, Y_n$.

COROLLARY. *Under the conditions of Theorem* 1 *the solutions of* (1) *may be expressed in the form*

$$y^i = C^i \exp\left(\sum_{\alpha=1}^{p} \lambda_\alpha^i x^\alpha \right), \qquad i = 1, \cdots, n,$$

where the C^i are arbitrary real numbers.

Proof. Following linear transformations on R^n and R^p, each $A_\alpha = \operatorname{diag}(\lambda_\alpha^1, \cdots, \lambda_\alpha^n)$. Then if y^i have the above form,

$$\frac{\partial y^i}{\partial x^\alpha} = \lambda_\alpha^i C^i \exp\left(\sum_{\alpha=1}^{n} \lambda_\alpha^i x^\alpha \right)$$

$$= \lambda_\alpha^i y^i = \sum_{j=1}^{n} A_{\alpha j}^i y^j.$$

Given any initial values y_0^i, x_0^α, the above solution with $C^i = y_0^i / \exp\left(\sum_{\alpha=1}^{p} \lambda_\alpha^i x_0^\alpha\right)$ passes through these initial values. Since solutions are all uniquely determined by initial values, every solution must have the stated form.

3. Exponential matrices. In ordinary linear differential equations one may express the solutions in terms of exponential matrix functions [**3**, p. 70]. Because the matrices A_α commute this is also possible here. If $C = (C_i^j)$ is a matrix of functions $C_i^j(x^1, \cdots, x^p)$, then $(\partial/\partial x^\alpha)C$ is defined to be the matrix $(\partial C_i^j / \partial x^\alpha)$. Observe that $(\partial/\partial x^\alpha)(CD) = (\partial C/\partial x^\alpha)D + C(\partial D/\partial x^\alpha)$.

LEMMA. *Let* $A_1, \cdots, A_p$ *be commuting* $n \times n$ *matrices of real numbers. If* $C = \sum_{\alpha=1}^{p} x^\alpha A_\alpha$ *then*

$$\frac{\partial}{\partial x^\alpha} C^n = nC^{n-1}A_\alpha.$$

Proof. This is true for $n=1$, and if true for $n-1$, then

$$\begin{aligned}\frac{\partial}{\partial x^\alpha} C^n &= \frac{\partial}{\partial x^\alpha} C^{n-1}C = \left(\frac{\partial}{\partial x^\alpha} C^{n-1}\right)C + C^{n-1}\frac{\partial}{\partial x^\alpha} C \\ &= (n-1)C^{n-2}A_\alpha C + C^{n-1}CA_\alpha.\end{aligned}$$

The hypothesis that $A_\alpha A_\beta = A_\beta A_\alpha$ implies that $A_\alpha C = CA_\alpha$, and the conclusion follows at once.

Let I denote the identity matrix.

PROPOSITION. *If* $C = \sum_{\alpha=1}^{p} x^\alpha A_\alpha$ *where* $A_1, \cdots, A_p$ *are* $n \times n$ *commuting matrices of real numbers, then*

$$e^C = I + C + \frac{1}{2!}C^2 + \frac{1}{3!}C^3 + \cdots$$

converges uniformly for all $(x^1, \cdots, x^p) \in R^p$, *and*

$$\frac{\partial}{\partial x^\alpha} e^C = e^C A_\alpha.$$

Proof. The uniform convergence follows as in the single-variable case, and then one may differentiate term-by-term. The previous lemma then completes the proof.

THEOREM 2. *Let the matrices* $A_\alpha = (A_{\alpha i}^j)$, $\alpha = 1, \cdots, p$ *commute, and let*

$$Y = \exp\left(\sum_{\alpha=1}^{p} x^\alpha A_\alpha\right) = (y_i^j).$$

Then if $a^1, \cdots, a^n$ *are any real numbers,* $y^i = \sum_{j=1}^{n} a^j y_j^i$, $i = 1, \cdots, n$ *is a solution of*

$$\frac{\partial y^i}{\partial x^\alpha} = \sum_{j=1}^{n} A_{\alpha j}^{\ i}\, y^j,$$

and conversely every solution can be written in this form for some $a^1, \cdots, a^n$.

Proof. By the previous proposition,

$$\frac{\partial y_i^j}{\partial x^\alpha} = \sum_{k=1}^{n} y_i^k A_{\alpha k}^{\ i}$$

and from this it follows that $y^1, \cdots, y^n$ are solutions. Conversely, every solution is uniquely determined by its initial values (y_0^i, x_0^α). Letting

$$(w_i^j) = \exp\left(-\sum_{\alpha=1}^{p} x_0^\alpha A_\alpha\right)$$

and $a^k = \sum_{k=1}^{n} w_k^i y_0^k$ $(i=1, \cdots, n)$ one obtains a solution which passes through these initial values.

A CRITERION FOR EXTREMAL POLYGONS OF A VERTEX SET

KENNETH LEBENSOLD, The City College of New York

1. Introductory remarks and definition of rearrangeability. We consider the problem of finding the shortest and longest polygons having n distinct points as vertices (the Traveling Salesman Problem). We denote the length of a polygon P by $l(P)$. The purpose of this paper is to produce a necessary and sufficient condition on a polygon that it be extremal in the set of all polygons through its vertices; we denote the vertex set by V, and call the set of these polygons the covertex class $P(V)$.

More specifically, we wish to find a subset $P'(V)$ of $P(V)$ so that if $l(P) \leqq \min_{Q\in P'(V)} l(Q)$, then $l(P) = \min_{Q\in P(V)} l(Q)$, that is, if the length of P is not greater than the length of Q for all Q in $P'(V)$, it is not greater than the length of Q for all Q in the covertex class of V. Clearly $P'(V) = P(V)$ is such a subset. The set $P'(V)$ will depend on the particular polygon P in $P(V)$. Exactly analogous results for maxima are obtainable by reversing all the inequalities in the proof for minima.

Suppose that (P, Q) is a pair of polygons with the same vertices. Suppose that (R, S) is another pair of polygons, each having the same vertex set as P and Q. Suppose further that every edge on one of the polygons (P, Q) is on one of the polygons (R, S), and every edge on both P and Q is on both R and S, and P, Q, R, S are all different. Then (R, S) is called a rearrangement of (P, Q) and (P, Q) is said to be rearrangeable. For example, let a hexagon have its vertices numbered in order 123456, call this P and suppose Q is 136245. Then $(R, S) = (134562, 154236)$ is a rearrangement of (P, Q).

If (R, S) is a rearrangement of (P, Q), there are $2n$ edges of (R, S) and $2n$ of (P, Q). Since (R, S) contains all the edges of (P, Q) and repeats all repeated edges of (P, Q), it has all the $2n$ sides of (P, Q). Since (R, S) has only $2n$ sides,

CONCERNING CONSECUTIVE DERIVED SETS

JOE TUCKER, Auburn University

Let M be a subset of a topological space S and for k a nonnegative integer let $M^{(k+1)}$ be the set of all limit points (i.e., the derived set) of $M^{(k)}$, where $M^{(0)}=M$.

DEFINITION. *For a subset M of S the sequence of derived sets of M is the sequence* $M^{(0)}, M^{(1)}, \cdots, M^{(k)}, \cdots$.

DEFINITION. *If for some positive integer k the sequence of derived sets of a subset M of S is such that $M^{(i)}\neq M^{(j)}$ for $0\leqq i<j<k$, but $M^{(0)}=M^{(k)}$, then the sequence is said to be periodic with period k.*

The primary purpose of this paper is to present one theorem concerning the period of periodic sequences of derived sets in a topological space. First, however, consider the more general Frechet space (V), [1].

For any positive integer $k>1$ a Frechet space (V) may be constructed so that for some subset the sequence of derived sets will be periodic with period k. In a Frechet space (V) neighborhoods are defined locally and thus if v is a neighborhood of p and $q\in v$, then v is not necessarily a neighborhood of q. Consider the finite point set $S=\{a_i\}_{i=1}^{k}$ and let $V=\{v(a_i)\}_{i=1}^{k}$, where $v(a_1)=\{a_1, a_k\}$ and $v(a_i)=\{a_{i-1}, a_i\}$ for $i\neq 1$, be the collection of subsets (neighborhoods) of S which are associated with the points in S. Now for the subset $M^{(0)}=\{a_i\}_{i=1}^{k-1}$ the consecutive derived sets are: $M^{(1)}=S-a_1$, $M^{(2)}=S-a_2$, $\cdots$, $M^{(j)}=S-a_j$, $\cdots$. Thus $M^{(k)}=S-a_k=M^{(0)}$ and the sequence has period k in the space (S, V).

If a space is such that every derived set is closed, (e.g., a Hausdorff space), then every periodic sequence of derived sets will have period 1. This follows from the inclusions $M^{(1)}\supset M^{(2)}\supset\cdots\supset M^{(k)}\supset\cdots$ and from the fact that if $M=M^{(k)}$, then $M^{(1)}=M^{(k+1)}$. In topological spaces in which a derived set is not necessarily closed, however, the period of a periodic sequence may be greater than 1, as is shown by the following example. Let $S=\{a, b, c\}$ and let a basis be the subsets $R_1=\{a, b\}$ and $R_2=S$. Now for $M=\{a, c\}$ the derived sets are: $M^{(1)}=\{b, c\}$, $M^{(2)}=\{a, c\}$, $\cdots$, and thus the period is 2. That 2 is the maximum period in a topological space is established as follows.

LEMMA 1. *Let (S, R) be a topological space. If $M\subset S$ and $M=M^{(k)}$ for some positive integer k, then*

$$M\cup M^{(1)}=M^{(1)}\cup M^{(2)}=\cdots=M^{(k-1)}\cup M.$$

Proof. When $k=1$, the lemma is trivially true. Now since $\mathrm{cl}(M)=\mathrm{cl}(\mathrm{cl}(M))$, $\mathrm{cl}(M)=M\cup M^{(1)}$ and $\mathrm{cl}(M\cup M^{(1)})=\mathrm{cl}(M)\cup\mathrm{cl}(M^{(1)})$, then $\mathrm{cl}(M)=\mathrm{cl}(M)\cup\mathrm{cl}(M^{(1)})$ and hence $\mathrm{cl}(M)\supset\mathrm{cl}(M^{(1)})$. Similarly $\mathrm{cl}(M^{(1)})\supset\mathrm{cl}(M^{(2)})$, $\cdots$, $\mathrm{cl}(M^{(k-1)})\supset\mathrm{cl}(M^{(k)})$ and thus

$$\mathrm{cl}(M) = \mathrm{cl}(M^{(1)}) = \mathrm{cl}(M^{(2)}) = \cdots = \mathrm{cl}(M^{(k-1)}).$$

Therefore $M\cup M^{(1)}=M^{(1)}\cup M^{(2)}=\cdots=M^{(k-1)}\cup M$.

LEMMA 2. *If k is a positive integer and M is a subset of S whose sequence of derived sets is periodic with period k, then each term in the sequence is a subset of S whose sequence of derived sets is periodic with period k.* (This follows from the definition of periodic sequences.)

THEOREM. *Let (S, R) be a topological space and let $M\subset S$. If the sequence of consecutive derived sets of M is periodic, then the period is not greater than* 2.

Proof. Suppose that $p\in M-M^{(2)}$. Then there exists an element R_1 of R such that $p\in R_1$ and $R_1\cap M^{(1)}=p$ (by Lemma 1, $p\in M^{(1)}$). But since $p\in M^{(1)}$, R_1 contains a point q of M distinct from p and hence not in $M^{(1)}$. So there exists an element R_2 of R which contains q but no point of $M-q$. In particular, R_2 does not contain p. Let R_3 be an element of R such that $q\in R_3\subset R_1\cap R_2$. But q being in $M-M^{(1)}$ is, by Lemma 1, in $M^{(2)}$. Hence, R_3 must contain a point of $M^{(1)}$, which is impossible. Therefore $M\subset M^{(2)}$.

Suppose that $p\in M^{(2)}-M$. Again by Lemma 1 $p\in M^{(1)}$. Now by Lemma 2 and the preceding paragraph,

$$M^{(1)}\subset M^{(3)}, \qquad M^{(2)}\subset M^{(4)}, \cdots, M^{(k-2)}\subset M^{(k)}.$$

So $p\in M^{(3)}$, $p\in M^{(4)}$, $\cdots$, $p\in M^{(k)}=M$. Thus $M^{(2)}\subset M$ and hence $M=M^{(2)}$; therefore, the period is not greater than 2.

FINITE PROJECTIVE PLANES WITH NONSOLVABLE TRANSITIVE COLLINEATION GROUPS

V. H. KEISER, JR., Whitman College

Introduction. In [4] Higman and McLaughlin proved the following

THEOREM 1. *If π is a finite projective plane of odd order n with a flag-transitive collineation group G and either n is not a square or $n=m^2$ with $m\equiv 3 \pmod 4$, then π is desarguesian and G contains the little projective group of π.*

Using essentially the same methods, but applying some new results which were not available to them, one can obtain the following more general

THEOREM 2. *If π is a finite projective plane with a transitive non-solvable collineation group G and either n is not a square or $n=m^2$ with $m\equiv 2, 3 \pmod 4$, then π is desarguesian and G contains the little projective group of π.*

Before proceeding further, we first note that a flag-transitive collineation group of a finite projective plane of odd order is necessarily non-solvable from which it follows immediately that Theorem 1 is a special case of Theorem 2.

Known Results Used in the Proof of Theorem 2:

A. FEIT-THOMPSON THEOREM. *Every nonsolvable group is of even order* [2].

B. BAER'S THEOREM. *Let ϕ be an involution in a projective plane of order n. Then either* (1) *$n=m^2$ and the fixed points and lines of ϕ form a subplane of order m, or* (2) *ϕ is a perspectivity. In case* (2) *if n is odd, ϕ is a homology and if n is even, ϕ is an elation.* [1]

C. WAGNER'S THEOREM. *Let π be a projective plane and G a transitive group of collineations of π. If G has a non-trivial perspectivity, then π is desarguesian and G contains the little projective group of π.* [5]

D. *Let G be a permutation group and H a subgroup of G. Let $\mathfrak{S}$ be the set of points left fixed by H. Then the normalizer of H in G will permute the points of $\mathfrak{S}$ among themselves.*

E. *The order of a finite simple group is divisible either by* 12 *or by the cube of the smallest prime dividing its order.* (See [3] Corollary 14.3.1.)

Proof of Theorem 2. Theorem 2 follows immediately from Wagner's Theorem and the following lemma.

LEMMA. *If π is a finite projective plane with a non-solvable collineation group G and either n is not a square or $n=m^2$ with $m\equiv 2, 3 \pmod 4$, then G contains an involutory perspectivity.*

Proof. By the Feit-Thompson Theorem, G, being non-solvable, is of even order hence contains an involution. We consider two cases.

(a) There is an involution ϕ which does not fix a subplane. Then by Baer's Theorem ϕ is a perspectivity and we are done.

(b) Every involution in G fixes a subplane. (We will show that in fact this case does not occur.) By Baer's Theorem this can occur only if $n=m^2$ and the fixed subplanes are of order m. The Feit-Thompson Theorem together with result E applied to G tell us that the order of G is divisible by 4. Hence either

(b′) G contains an element of order 4 or

(b″) The Sylow 2-subgroups of G are elementary abelian.

Suppose b′ holds. Let η be of order 4. Then η^2 is an involution fixing a subplane π_0 of order m and since η is in the normalizer of η^2, it follows by result D that η permutes the points of π_0 among themselves. By Baer's Theorem η^2 fixes no points of $\pi-\pi_0$ ($\pi-\pi_0$ represents the set of points in π that are not in

π_0) and since η^2 clearly fixes all the points fixed by η, it is also true that η fixes no points of $\pi-\pi_0$. Therefore η permutes the points of $\pi-\pi_0$ in cycles of length four so that $|\pi-\pi_0| \equiv 0 \pmod 4$. Thus we must have

$$(n^2+n+1)-(m^2+m+1) \equiv 0 \pmod 4. \tag{1}$$

But if $m \equiv 2, 3 \pmod 4$, then

$$(n^2+n+1)-(m^2+m+1) \equiv (0+0+1)-(0+2+1) \quad \text{or} \quad (1+1+1)-(1+3+1) \pmod 4$$

respectively and both of these are congruent to 2 (mod 4) contradicting equation (1).

Suppose b'' holds. Let ϕ and η be elements of order two in the same Sylow 2-subgroup of G. We consider two subcases.

(b''−1) ϕ and η fix the same subplane. Since $\phi\eta$ is also of order two, it fixes the same subplane and no other points. Each nonidentity element of the group (ϕ, η) thus fixes the points of π_0 and no others. Since (ϕ, η) is of order 4, this implies that $|\pi-\pi_0| \equiv 0 \pmod 4$ contrary to the fact that, as already shown, this number is congruent to 2 (mod 4).

(b''−2) ϕ and η fix different subplanes π_ϕ and π_η. Since ϕ and η commute, each is contained in the normalizer of the other. Hence by result D ϕ permutes the points of π_η among themselves and η permutes the points of π_ϕ among themselves. Thus ϕ and η restricted to π_η and π_ϕ respectively are perspectivities. (They cannot fix subplanes of π_η and π_ϕ since m is not a square.) In particular they are elations or homologies according as $m \equiv 2$ or 3 (mod 4). Now $\phi\eta$ fixes a subplane $\pi_{\phi\eta}$ and we can assume that $\pi_{\phi\eta}$ is different from π_ϕ and π_η since otherwise this case reverts to (b''−1). Clearly $\pi_{\phi\eta} \cap \pi_\phi \cap \pi_\eta$ consists of the $m+1$ or $m+2$ points fixed by both ϕ and η. ($m+1$ if ϕ and η are elations of π_η and π_ϕ, $m+2$ if they are homologies.) As above, the group (ϕ, η) of order 4 permutes the points of $\pi-(\pi_{\phi\eta} \cup \pi_\phi \cup \pi_\eta)$ among themselves in cycles of length four so that

$$|\pi-(\pi_{\phi\eta} \cup \pi_\phi \cup \pi_\eta)| \equiv 0 \pmod 4.$$

But

$$|\pi-(\pi_{\phi\eta} \cup \pi_\phi \cup \pi_\eta)| = (n^2+n+1)-3(m^2+m+1)+2(m+1 \text{ or } m+2)$$

according as $m \equiv 2$ or 3 (mod 4). In both cases, however, this number is congruent to 2 (mod 4).

From these contradictions we conclude that case (b) does not occur. This leaves (a) and we have already shown that in this case there is an involutory perspectivity.

Added in proof: In a private communication Professor Peter Dembowski has kindly pointed out that the hypothesis of nonsolvability is stronger than necessary. In both Theorem 2 and the Lemma, "nonsolvable collineation

group G" can be replaced by the weaker "collineation group G with $|G| \equiv 0 \pmod 4$."

This paper represents part of a Ph. D. dissertation written at the University of Colorado, Boulder, under the direction of Professor Richard Roth.

A MINIMUM PROBLEM CONNECTED WITH COMPLETE RESIDUE SYSTEMS IN THE GAUSSIAN INTEGERS

N. R. HARDMAN AND J. H. JORDAN, Washington State University

1. A Gaussian integer, γ, is a complex number that can be expressed as $\gamma = a+bi$, where a and b are real integers and i is the so-called imaginary unit. The set of Gaussian integers with the usual operations of addition and multiplication forms a unique factorization domain.

Small case Greek letters will be used to represent Gaussian integers.

Some definitions about Gaussian integers, given in [2], are:

DEFINITION. *γ divides α means there is a β such that $\beta\gamma = \alpha$. Notation:* $\gamma \mid \alpha$.

DEFINITION. $\alpha \equiv \beta \pmod \gamma$ *means* $\gamma \mid \alpha - \beta$.

This congruence relation for a fixed γ is an equivalence relation on the set of Gaussian integers. The set of equivalence classes formed with respect to this equivalence relation is called the complete residue system modulo γ. As is shown in [1] and in [2] the cardinality of a complete residue system modulo $\gamma = a+bi$ is $a^2+b^2 = N(\gamma)$ the norm of γ.

Following the notation used in [1],

(i) the symbol CRS(mod γ) for $\gamma = a+bi$ will stand for the complete residue system modulo γ, and

(ii) a representation of the CRS(mod γ) will be a set of a^2+b^2 incongruent Gaussian integers modulo γ. Several representations are exhibited in [1].

A problem suggested in [1] was that of finding for each γ a representation R_γ of CRS(mod γ) such that for any representation, T_γ, of the CRS(mod γ)

$$\sum_{\alpha \in R_\gamma} |\alpha| \leqq \sum_{\beta \in T_\gamma} |\beta| .$$

It is the purpose of this paper to settle this problem by exhibiting the R_γ desired and also to indicate which of these R_γ are unique solutions to the problem. The appropriate result is

THEOREM. *Let A be the set of Gaussian integers inside the square with vertices at $(\pm 1 \pm i)\gamma/2$ and let B be the set of Gaussian integers on the half open line segments $(\pm(-1+i)\gamma/2, (-1-i)\gamma/2)$. Then $R_\gamma = A \cup B$ is the representation with the desired "minimal" property. Further this is the unique representation with the desired "minimal" property if and only if $N(\gamma) = a^2+b^2$ is odd.*

Proof: We will prove the case when $N(\gamma) = a^2+b^2$ is odd or equivalently when $(1+i) \nmid \gamma$.

LEMMA 1. *If $m \not\equiv n \pmod 2$ and a line, L, with slope m/n passes through a point $(t+\frac{1}{2}, s+\frac{1}{2})$ with t and s integers then L has no points which have both coordinates integers.*

Proof: The equation for L is

$$ny - ns - n/2 = mx - mt - m/2$$

which does not permit x and y to be integers simultaneously.

COROLLARY. *If $(1+i) \mid \gamma$ then $B = \varnothing$.*

Proof: $\gamma = a+bi$ where $a \not\equiv b \pmod 2$.

LEMMA 2. *If $(1+i) \nmid \gamma = a+bi$ then A has a^2+b^2 elements in it.*

Proof: Separate the square $(\pm 1 \pm i)\gamma/2$ into the five areas; the four triangles A_j with vertices $i^j(a-b+(a+b)i)/2$, $i^j(-a-b+(a-b)i)/2$, $i^j(a-b+(a-b)i)/2$, $j = 0, 1, 2, 3$; and the square with vertices $i^j(a-b+(a-b)i)/2$. Now the sides of each area are void of Gaussian integers by Lemma 1. By the similarity of the four triangles it suffices to count the Gaussian integers in one and multiply by 4. To count the Gaussian integers in A_0 consider the rectangle with the vertices of A_0 and the other vertex at $(-a-b+(a+b)i)/2$. This rectangle contains twice as many Gaussian integers as does A_0 since the diagonal is void of Gaussian integers. There are, however, ab Gaussian integers in this rectangle; hence A_0 contains $ab/2$ Gaussian integers. The number of Gaussian integers in $\bigcup_{j=0}^{3} A_j$ is therefore $2ab$. The number of Gaussian integers in the square is $|a-b|\,|a-b|$ or $a^2-2ab+b^2$. Hence the number of elements in A is a^2+b^2.

This proof reminds one of a proof of the Pythagorean Theorem.

LEMMA 3. *Let $\alpha \in A$ then $|\alpha| < |\beta|$ for all $\beta \equiv \alpha \pmod \gamma$, $\beta \neq \alpha$.*

Proof. Let $\alpha/\gamma = r+si$. Now $-\frac{1}{2} < r < \frac{1}{2}$ and $-\frac{1}{2} < s < \frac{1}{2}$. Since $\beta = \alpha + \delta\gamma$, it follows that $\beta/\gamma = \alpha/\gamma + \delta = r+c+(s+d)i$. But since c and d are integers $|r+c| > |r|$ unless $c = 0$ and $|s+d| > |s|$ unless $d = 0$. It now follows that

$$|\beta/\gamma| = \sqrt{(r+c)^2 + (s+d)^2} > \sqrt{r^2+s^2} = |\alpha/\gamma|$$

or equivalently $|\beta| > |\alpha|$, unless c and d are 0 in which case $\beta = \alpha$.

Now the proof of the theorem follows immediately from Lemmas 2 and 3 in case $(1+i) \nmid \gamma$, since $B = \varnothing$ and A is a CRS (mod γ) with the minimal property.

The proof for the case when $(1+i) \mid \gamma$ is slightly more involved and is omitted. When $B \neq \varnothing$ then the uniqueness fails since for each $\beta \in B$ there is an α such that $\alpha \equiv \beta \pmod{\gamma}$ and $|\alpha| = |\beta|$, in particular either $\beta+\gamma$ or $\beta+i\gamma$ has that property.

ON A PROPERTY OF THE b-ADIC EXPRESSION OF INTEGERS

GUY HIRSCH, Université de Bruxelles

Let $N = \beta_n b^n + \beta_{n-1} b^{n-1} + \cdots + \beta_1 b + \beta_0$ $(0 \leqq \beta_i \leqq b-1;\ b > 1)$ be the b-adic expression of the (positive) integer N. The sum

$$w_b(N) = \beta_0 + \beta_1 + \cdots + \beta_n$$

of the "b-adic digits" will be called the *b-adic weight* of N.

Denote by B_1 the set of the numbers $m - w_b(m) + (b-1)$, where m is any number divisible by b; denote by B_q $(q \geqq 1)$ the set of the numbers

$$m - w_b(m) + (b^q - 1),$$

where m is any number divisible by b^q.

REMARK. $m = 0$ being divisible by any number, with $w_b(0) = 0$, the number $b^q - 1$ belongs to B_q.

THEOREM. *Every multiple of $(b-1)$ appears exactly once in (exactly) one of the sets B_q.*

Denoting by $c_i = (b^i - 1)/(b-1) = 1 + b + \cdots + b^{i-1}$ the number whose b-adic expansion consists of i one's, another way of stating the theorem is as follows:

Let m_q be any (nonnegative) number divisible by b^q $(q \geqq 1)$; subtract from m_q the sum of its b-adic digits, and divide this difference by $b-1$. Add to the quotient the number c_q whose b-adic expansion consists of q one's. Every nonnegative integer is obtained just once in this way.

REMARKS. For $b = 2$, the theorem states that for every positive integer t there exists a unique (positive) integer q such that t is expressible uniquely in

the form $m-w_2(m)+(2^q-1)$, where m is divisible by 2^q and $w_2(m)$ denotes the dyadic weight of m, i.e. the number of one's in the dyadic expression of m.

Under this form, the theorem plays a role in algebraic topology (where it is used to prove that elements of a certain form in the Steenrod algebra yield exactly one class for every dimension).

Proof of the theorem. (The author expresses his thanks to the referee, who suggested a shorter and simpler proof, which is essentially given below.)

From $m_q-w_b(m_q)=\beta_n(b^n-1)+\beta_{n-1}(b^{n-1}-1)+\cdots+\beta_q(b^q-1)$, it follows that

$$(m_q - w_b(m_q))/(b-1) = \beta_n c_n + \cdots + \beta_q c_q.$$

The theorem states that each nonnegative integer a is expressible uniquely in the form

$$(*)\quad (m_q - w_b(m_q))/(b-1) + c_q = \beta_n c_n + \cdots + \beta_{q+1}c_{q+1} + (\beta_q + 1)c_q,$$

with $0\leqq\beta_i\leqq b-1$.

We first prove the existence of m_q for a given a. Because $a\geqq 1$ and $c_1=1$, there exists $n\geqq 1$ such that

$$c_1 < \cdots < c_n \leqq a < c_{n+1}.$$

Write $r_{n+1}=a$, and denote by r_i the remainder of the division of r_{i+1} by c_i, α_i denoting the quotient; let r_{q+1} be the last nonzero remainder.

One has

$$\begin{aligned} a &= \alpha_n c_n + r_n \\ r_n &= \alpha_{n-1}c_{n-1} + r_{n-1} \\ &\cdots\cdots\cdots \\ r_{i+1} &= \alpha_i c_i + r_i \\ &\cdots\cdots\cdots \\ r_{q+1} &= \alpha_q c_q \end{aligned}$$

with $1\leqq r_i<c_i$, $\alpha_i\geqq 0$ for $i=n, \cdots, q+1$; $\alpha_q\geqq 1$. From

$$bc_i + 1 = c_{i+1} > r_{i+1} = \alpha_i c_i + r_i \geqq \alpha_i c_i + 1$$

we get $\alpha_i<b$ for $i=n, \cdots, q+1$; from $bc_q+1=c_{q+1}>r_{q+1}=\alpha_q c_q$ we get $\alpha_q\leqq b$. Let $\beta_i=\alpha_i$ for $i>q$, and $\beta_q=\alpha_q-1$; then $0\leqq\beta_i\leqq b-1$ for all i and

$$\beta_n b^n + \beta_{n-1}b^{n-1} + \cdots + \beta_q b^q$$

is the b-adic expansion of m_q, divisible by b^q.

We now prove the uniqueness of the expression (*). Suppose that we could have

$$\begin{aligned} a &= \beta_n c_n + \beta_{n-1}c_{n-1} + \cdots + \beta_q c_q + c_q \\ &= \beta'_n c_n + \beta'_{n-1}c_{n-1} + \cdots + \beta'_{q'}c_{q'} + c_{q'} \end{aligned}$$

with $0 \leqq \beta_i \leqq b-1$, $0 \leqq \beta_i' \leqq b-1$, where, for at least one i, $\beta_i' \neq \beta_i$.

Let j be the largest index for which $\beta_j' \neq \beta_j$; suppose that $\beta_j' > \beta_j$; then $j > q$. Equating the two expressions of a, we would have

$$c_j \leqq (\beta_j' - \beta_j)c_j = (\beta_{j-1} - \beta_{j-1}')c_{j-1} + \cdots + (\beta_i - \beta_i')c_i + \cdots + c_q - c_{q'}$$

(where $\beta_i = 0$ for $i < q$, $\beta_i' = 0$ for $i < q'$). Dropping all negative terms on the right hand side, we would have $c_j \leqq \beta_{j-1}c_{j-1} + \cdots + \beta_q c_q + c_q$ or

$$\beta_{j-1}c_{j-1} + \cdots + \beta_q c_q \geqq c_j - c_q = (b^{j-1} + \cdots + b + 1) - (b^{q-1} + \cdots + b + 1)$$
$$= b^{j-1} + b^{j-2} + \cdots + b^q.$$

But $\beta_i \leqq b-1$, hence the lefthand side is not larger than

$$(b-1)c_{j-1} + (b-1)c_{j-2} + \cdots + (b-1)c_q = (b^{j-1} - 1) + (b^{j-2} - 1) + \cdots$$
$$+ (b^q - 1) = b^{j-1} + b^{j-2} + \cdots + b^q - (j-q) < b^{j-1} + b^{j-2} + \cdots + b^q,$$

which proves that the above inequality is impossible.

ONE MORE REASON WHY SEQUENCES ARE NOT ENOUGH

BERNARD KRIPKE, University of California, Berkeley

It is common knowledge that many interesting properties of nonmetric topologies cannot be characterized by sequential convergence. In particular, sequences are inadequate to characterize closure, compactness, and the like in the weak * topologies on infinite-dimensional Banach duals. One could easily conclude that one must always operate with nets in weak * topologies—that sequences will never do. Friends of Sequential Convergence will find solace from such extremism in [1]. The present note, however, strikes one more blow at Sequentialism by exhibiting a Banach space B and a linear functional Φ on its dual B^* which is weak * sequentially continuous, but not weak * continuous. That is, although Φ carries weak * convergent *sequences* in B^* into convergent sequences of real numbers, the inverse image under Φ of a point is not closed in the weak * topology of B^*.

Let S be an uncountable set, and let B be the family of all bounded real-valued functions on S which vanish at all but countably many points of S. If $x \in B$, its *support* is $\sigma(x) = \{s \in S: x(s) \neq 0\}$. Norm B by setting $\|x\| = \sup\{|x(s)| : s \in S\}$. This makes B into a Banach space, for if $x_n \to x$ uniformly on S, x vanishes outside $U_{n=1}^{\infty} \sigma(x_n)$.

Let $f \in B^*$ be a continuous linear functional on B. A subset T of S is a *supporting set* for f if $f(x) = 0$ whenever $\sigma(x)$ is disjoint from T. If $T \subseteq U$, then U is also a supporting set for f. Let us show that each f in B^* has a *countable* supporting set. Since f is bounded, there is a sequence $\{x_n\}$ in B such that $\|x_n\| = 1$ for each n and $\lim f(x_n) = \|f\|$. Put $T = U_{n=1}^{\infty} \sigma(x_n)$. If $\sigma(y)$ does not interest T and $\|y\| \leqq 1$, then $\|y + x_n\| = 1$ for each n. Suppose that $f(y) > 0$. Choose an n

so large that $f(x_n) > \|f\| - f(y)$. Then

$$f(y) + f(x_n) \leqq \|f\| \, \|y + x_n\| \leqq \|f\|,$$

a contradiction. Therefore, T is a supporting set for f.

If T is a countable subset of S, let $\chi_T \in S$ be the function which is 1 on T and 0 outside T. Suppose $T \subseteq U$ and both are countable supporting sets for f. Then the support of $\chi_U - \chi_T = \chi_{U-T}$ is disjoint from T, so that $f(\chi_U - \chi_T) = 0$. It follows that if T and U are any two countable supporting sets for f,

$$f(\chi_U) = f(\chi_{U \cup T}) = f(\chi_T).$$

We can thus define a unique function Φ from B^* to the reals as follows: if $f \in B^*$ and T supports f, put $\Phi(f) = f(\chi_T)$. It is clear that Φ is linear.

Let us first show that Φ is weak * sequentially continuous. If $\{f_n\}$ is a sequence in B^* which is weak * convergent to f, then

$$T = \sigma(f) \cup U_{n=1}^{\infty} \sigma(f_n)$$

is a countable supporting set for f and for each f_n. Then

$$\Phi(f) = f(\chi_T) = \lim f_n(\chi_T) = \lim \Phi(f_n),$$

where the central equation follows from the definition of weak * convergence for functionals in B^* as pointwise convergence on B.

Next, let us show that Φ is not weak * continuous, by showing that $C = \Phi^{-1}(1) = \{f \in B^* : \Phi(f) = 1\}$ is not weak * closed. Indeed, it will be shown that the zero functional Z ($Z(x) = 0$ for all $x \in B$) is in the weak * closure of C, although it clearly is not in C. Any neighborhood N of Z in B^* contains a basic neighborhood of the form

$$N(x_1, \cdots, x_n) = \{f \in B^* : |f(x_j)| < 1 \quad \text{for} \quad j = 1, \cdots, n\},$$

where $x_1, \cdots, x_n$ are some elements of B. Take any point $s \in S$ outside of $\sigma(x_1) \cup \cdots \cup \sigma(x_n)$. If we put $f(x) = x(s)$, then f is an element of B^*, and moreover, f is in $N(x_1, \cdots, x_n) \subset N$ because $x_1, \cdots, x_n$ all vanish at s. But $\Phi(f) = f(\chi_{\{s\}}) = 1$, so that f is also in C. That is, every weak * neighborhood of Z intersects C, so that Z is in the weak * closure of C.

Finally, it is amusing to remark that although we have shown that every element of B^* has a countable supporting set (by implicitly using the Axiom of Choice), there is no way to pick a *smallest* countable support for each element of B^*. Consider the subspace L of B consisting of functions on S which vanish at ∞. That is, x is in L if and only if for each $\epsilon > 0$, there are only finitely many points in S at which $|x(s)| \geqq \epsilon$. It is easy to see that L is closed, and is not all of B. According to the Hahn-Banach Theorem [2, page 64], there is a nonzero element f of B^* which vanishes on L. If T is any supporting set for f and s is in T, then $T - \{s\}$ also supports f. Indeed, $\{s\}$ is countable, so that $\chi_{\{s\}} \in L$, and $f(\chi_{\{s\}}) = 0$. If x vanishes outside $T - \{s\}$, then $x - x(s) \cdot \chi_{\{s\}}$ vanishes outside T, and

$$f(x) = f(x) - x(s)f(\chi_{\{s\}}) = f(x - x(s)\chi_{\{s\}}) = 0.$$

No matter what supporting set for f we choose, we can always find a smaller one.

A THEOREM ON SPACES OF CONSTANT CURVATURE

C. M. FULTON, University of California, Davis

To obviate comments on notation we will conform throughout to the one used in [1]. We wish to prove the following

THEOREM. *If in an n-dimensional Riemannian space there is a coordinate system x^i such that the Christoffel symbols* [1, p. 55] *satisfy the relation*

$$[k, ij] = p_k g_{ij} \tag{1}$$

for some functions p_k, then the space has constant curvature.

This theorem may be proved by using the Weyl tensor and/or Schur's theorem. Since this would require a special method for the case $n=2$, we prefer a treatment valid for all n. First of all we notice that the p's are components of a gradient because we may infer [1, p. 56] from (1) that $p_i=\partial_i \log \sqrt{g}$. It is now a matter of straightforward manipulation [1, pp. 55, 110] to derive the curvature tensor from (1). We find

$$R^a_{ijk} = g_{ik}\partial_j p^a - g_{ij}\partial_k p^a. \tag{2}$$

Changing to the covariant curvature tensor and making use of one of its symmetry properties [1, p. 112], we have

$$R_{hijk} = g_{ik}g_{ha}\partial_j p^a - g_{ij}g_{ha}\partial_k p^a = R_{ihkj} = g_{hj}g_{ia}\partial_k p^a - g_{hk}g_{ia}\partial_j p^a. \tag{3}$$

On multiplication by g^{hk} we obtain two expressions for the Ricci tensor, namely $g_{ia}\partial_j p^a - g_{ij}\partial_a p^a = g_{ia}\partial_j p^a - n g_{ia}\partial_j p^a$. Writing A for $(1/n)\partial_a p^a$ this gives rise to

$$g_{ia}\partial_j p^a = g_{ij}A \quad \text{and} \quad \partial_j p^a = \delta^a_j A. \tag{4}$$

With the aid of the covariant derivative $p^a_{,j}=\partial_j p^a + p^a p_j$ and (4) we get $p_{i,j} = g_{ij}A + p_i p_j$. Further covariant differentiation yields

$$p_{i,jk} - p_{i,kj} = g_{ij}A_{,k} - g_{ik}A_{,j} + g_{ik}A p_j - g_{ij}A p_k.$$

This is rewritten [1, p. 110] by means of a Ricci identity and (2) and (4) as follows:

$$p_a R^a_{ijk} = p_j g_{ik}A - p_k g_{ij}A.$$

Hence, by comparison, $g_{ij}A_{,k}=g_{ik}A_{,j}$, which implies that A is a constant. We now conclude on account of (4) that $p^i=Ax^i$ neglecting the constants of integration without loss of generality. Also, (3) shows that

$$R_{hijk} = A(g_{hj}g_{ik} - g_{hk}g_{ij})$$

and so [1, p. 117] $A=K$ is the constant Riemannian curvature of the space.

To conclude we determine the contravariant metric tensor from the relation for its partial derivatives [1, p. 56] which is equivalent to $g^{ik}_{,j}=0$. Thus, from (1), $\partial_j g^{ik} = -Kx^i\delta^k_j - Kx^k\delta^i_j$, whence it follows that $g^{ik} = -Kx^ix^k + c^{ik}$, the c's being arbitrary symmetric constants. If their reduced cofactors are denoted by c_{ik}, it is easily verified that

$$g_{ij} = c_{ij} + Kc_{ir}x^rc_{js}x^s/(1 - Kc_{ab}x^ax^b).$$

GENERALIZATION OF A RELATION INVOLVING RIGHT TRIANGLES

W. J. BLUNDON, Memorial University of Newfoundland

1. Introduction. Let R, r, s represent respectively the circumradius, inradius and semiperimeter of a triangle with sides a, b, c. It is well known that one of the angles of a triangle is a right angle if and only if $s=2R+r$. The purpose of this paper is to derive the corresponding equation for an angle of any given measure. It turns out that the relation is again linear in R, r, s. For an interesting account of related problems, see Coxeter [2]. We prove the following theorem.

THEOREM. *At least one of the angles of a triangle has measure θ if and only if* $s=2R\sin\theta+r\cot\theta/2$.

To prove this we need expressions for the elementary symmetric functions of the cosines of the angles in terms of R, r, s, as set forth in the following lemma.

LEMMA. *In every triangle*

$$\cos A\cos B\cos C = (s^2 - 4R^2 - 4Rr - r^2)/4R^2,$$

$$\sum \cos A\cos B = (s^2 - 4R^2 + r^2)/4R^2, \tag{1}$$

$$\sum \cos A = (R + r)/R.$$

2. *Proof of the Lemma.* From the basic identities, namely,

$$a + b + c = 2s$$

$$ab + bc + ca = s^2 + 4Rr + r^2$$

$$abc = 4Rrs,$$

we obtain after some computation the following identities. (See [1].)

$$\sum a^2b - \sum a^3 = 8rs(R + r), \tag{2}$$

$$2\sum a^2b^2 - \sum a^4 = 16r^2s^2. \tag{3}$$

With the help of the identities

$$\sum a^3b^3 = (\sum ab)(\sum a^2b^2) - abc\sum a^2b,$$

$$\sum a^5b = (\sum ab)(\sum a^4) - abc\sum a^3,$$

the identity $\sum ab(b^2+c^2-a^2)(c^2+a^2-b^2) = 2\sum a^3b^3 - \sum a^5b + abc\sum a^3$ becomes

$$\sum ab(b^2 + c^2 - a^2)(c^2 + a^2 - b^2) = 16r^2s^2(s^2 - 4R^2 + r^2). \tag{4}$$

Also, from (2) it follows easily that

$$\sum a(b^2 + c^2 - a^2) = 8rs(R + r). \tag{5}$$

Applying the law of cosines to (4) and (5), we have the second and third identities of the lemma.

Finally, the identity $a^2+b^2+c^2 = 2(s^2-r^2-4Rr)$ gives

$$\begin{aligned}\cos A \cos B \cos C &= \tfrac{1}{2}(1 - \cos^2 A - \cos^2 B - \cos^2 C)\\ &= \tfrac{1}{2}(\sin^2 A + \sin^2 B + \sin^2 C - 2)\\ &= (a^2 + b^2 + c^2)/8R^2 - 1\end{aligned}$$

which reduces to the first identity of the Lemma.

3. *Proof of the Theorem.* At least one of the angles of the triangle ABC has measure θ if and only if

$$(\cos\theta - \cos A)(\cos\theta - \cos B)(\cos\theta - \cos C) = 0. \tag{6}$$

Using (1), we may put (6) in the form

$$4R^2\cos^3\theta - 4(R^2+Rr)\cos^2\theta + (s^2-4R^2+r^2)\cos\theta - (s^2-4R^2-4Rr-r^2) = 0.$$

Solving for s^2 and taking the square root, we have

$$s = 2R(1 - \cos^2\theta)^{1/2} + r(1 + \cos\theta)^{1/2}/(1 - \cos\theta)^{1/2},$$

which reduces to $s = 2R\sin\theta + r\cot\theta/2$. This completes the proof of the theorem.

COROLLARY 1. *At least one of the angles of a triangle is* 60° *if and only if* $s = (R+r)\sqrt{3}$.

COROLLARY 2.

$$\begin{vmatrix} 1 & \sin A & \cot A/2 \\ 1 & \sin B & \cot B/2 \\ 1 & \sin C & \cot C/2 \end{vmatrix} = 0.$$

AN INFINITE GROUPOID WHICH ADMITS ONLY TRIVIAL TOPOLOGIES

J. R. HANSON, Madison College and Virginia Polytechnic Institute

Let $G=(a, b, c, \cdots)$ be a groupoid, i.e. a set closed under a binary operation. If U_x represents an open set containing the element x, the topology T is said to be admissible for the groupoid G provided for every product $a\cdot b=c$ in G and for every open set U_c in T there exist open sets U_a and U_b in T such that $U_a\cdot U_b\subseteq U_c$. A groupoid G will be called topologically trivial if the only admissible topologies for G are the trivial discrete and indiscrete topologies.

Let $I^+=(1, 2, 3, \cdots)$ be the positive integers with multiplication defined by $x\cdot y=1$ if $x\neq y$, and $x\cdot x=x+1$. The purpose of this note is to show that this infinite groupoid introduced by Doyle and Warne [1] is topologically trivial.

In what follows all small letters will represent elements of I^+.

LEMMA 1. *If (p) is an open set in an admissible topology for I^+, then (q) is open for all $q<p$.*

Proof. If $p>1$, $(p-1)(p-1)=(p)$. Thus there exists an open set U_{p-1} such that $U_{p-1}\cdot U_{p-1}=(p)$. This implies $U_{p-1}=(p-1)$, or $(p-1)$ is open. Proceed by induction.

LEMMA 2. *If I^+ admits a topology T which is not the discrete topology, the following statements are valid:*

(1) *There exists j in I^+ such that if U_k is in T and $k>j$, then 1 is in U_k.*

(2) *If U_1 is in T, then 2 is in U_1.*

(3) *If U is in T, U cannot consist of a single point.*

Proof. Clearly, there exists j in I such that each open set with respect to T containing j contains two or more elements. $j\cdot j=j+1$. Thus for U_{j+1} there exists U_j such that $U_j\cdot U_j\subseteq U_{j+1}$. But U_j contains elements r and j with $r\neq j$. Therefore, $r\cdot j=1$ belongs to U_{j+1}. Proceed by induction to complete the proof of (1).

(2) There are elements m and n in I each greater than the j of (1), with $m\neq n$ so that $m\cdot n=1$. Therefore, for any U_1 there exist U_m and U_n such that $U_m\cdot U_n\subseteq U_1$. By (1) 1 is in U_m and U_n so that $1\cdot 1=2$ is in U_1.

(3) If (p), $p>1$, were an open set, (1) would be an open set by Lemma 1. But (1) is not an open set by (2).

THEOREM. *I^+ with the given multiplication is topologically trivial.*

Proof. Suppose I^+ is not topologically trivial and T is a nontrivial admissible topology. Then by (3) no single point is an open set in T.

First, 1 is in U_j for all j in I^+. Clearly, 1 is in U_1. For $j>1$, $(j-1)\cdot(j-1)=j$ implies that there exists U_{j-1} such that $U_{j-1}\cdot U_{j-1}\subseteq U_j$. Since $(j-1)$ is not open, there exist r and s, $r\neq s$, in U_{j-1} so that $r\cdot s=1$ is in U_j.

Now suppose that k belongs to U_j for every j in I^+. Then $k+1$ belongs to U_j for every j. For U_j $(j\geqq 2)$ there exists U_{j-1} such that $U_{j-1}\cdot U_{j-1}\subseteq U_j$. Since k is in U_{j-1}, $k\cdot k=k+1$ is in U_j. For U_1 there exist U_r and U_s, $r\neq s$, such that $U_r\cdot U_s\subseteq U_1$. But k is in U_r and U_s, so $k\cdot k=k+1$ is in U_1. Hence the induction is complete, and $U_j=I^+$ for every j. But T was assumed to be nontrivial, a contradiction. Therefore, I^+ is topologically trivial.

The interested reader is invited to investigate, as the author has, which groups, semigroups, and groupoids can be topologically trivial.

A COINCIDENCE THEOREM

RAUL MACHUCA, Fairleigh Dickenson University, Teaneck

Let X be a T_1 topological space satisfying the first axiom of countability, Y a complete metric space and $f\colon X\to Y$ and $g\colon X\to Y$ continuous. A *compact* mapping is a mapping k such that $k^{-1}(K)$ is compact for each compact set K contained in the image of k.

THEOREM. *If $f(X)\subset g(X)$, f is a compact mapping with $f(X)$ closed, or g is a compact mapping with $g(X)$ closed, and for some $K<1$, $\delta(f(x), f(x'))\leqq K\delta(g(x), g(x'))$ for all x, $x'\in X$, then $f(t)=g(t)$ for some $t\in X$.*

Proof. Define a sequence $\{x_n\}\subset X$ such that $f(x_{n-1})=g(x_n)$ for $n=2, 3, \cdots$. Since $\delta(g(x_n), g(x_{n+1}))\leqq K\delta(g(x_{n-1}), g(x_n))$ with $K<1$, $\{g(x_n)\}$ is Cauchy in Y. Since Y is complete there exists $y\in Y$ such that $g(x_n)\to y\leftarrow f(x_n)$. By the hypothesis on compactness of f or g we have $f^{-1}(A)$ or $g^{-1}(A)$ compact in X, where A is the compact subset of Y consisting of the points of the sequence $\{f(x_n)\}$ plus its limit y. Thus $\{x_n\}$ has a convergent subsequence. It follows that $f(t)=g(t)$ where t is the limit of any such subsequence.

COROLLARY. *If $f\colon X\to X$ is a continuous mapping of a complete metric space X onto itself such that $\delta(f(x), f(x'))\geqq K\delta(x, x')$ for all x, $x'\in X$ and some $K>1$, then f has a fixed point.*

The corollary follows from an investigation of f^{-1}.

ONCE MORE THE BRAUER-RADEMACHER IDENTITY

P. Szüsz, Pennsylvania State University

The Brauer-Rademacher identity is the following:

$$\phi(r) \sum_{\substack{d \mid r \\ (d,n)=1}} d\mu\left(\frac{r}{d}\right)\frac{1}{\phi(d)} = \mu(r) \sum_{d \mid (r,n)} d\mu\left(\frac{r}{d}\right). \tag{1}$$

There are several proofs and generalizations of (1); see Subbarao [1] where references are given. In the present note I give a very short and simple proof of (1). It would be easy to give some generalizations in the same way (for instance that of Subbarao), but the essential idea is contained in the proof of (1).

First I show that if r is not square-free, then

$$\phi(r) \sum_{\substack{d \mid r \\ (n,d)=1}} d\mu\left(\frac{r}{d}\right)\frac{1}{\phi(d)} = 0. \tag{2}$$

Namely let p be a prime factor of r contained at least to the second power. The divisors of r, d and d' are called pairs, when r/d doesn't contain p, r/d' contains p exactly to the first power and $d/d' = p$. Since p is contained in r at least to the second power, we have $d/\phi(d) = d'/\phi(d')$ and

$$\mu\left(\frac{r}{d}\right) = -\mu\left(\frac{r}{d'}\right),$$

that is

$$d\mu\left(\frac{r}{d}\right)\frac{1}{\phi(d)} + d'\mu\left(\frac{r}{d'}\right)\frac{1}{\phi(d')} = 0. \tag{3}$$

Now we can separate all the divisors of r into three classes, the first two being pairs and the third, the terms of which are denoted by d'' consisting of the divisors of r for which $p^2 \mid (r/d'')$.

From (3) and $\mu(r/d'') = 0$ we obtain (2).

Now let r be square-free. Then we have

$$\phi(r) \sum_{d \mid r} d\mu\left(\frac{r}{d}\right)\frac{1}{\phi(d)} = 1; \tag{4}$$

namely, since r is square-free, $\phi(r) = \phi(d)\phi(r/d)$ for each divisor of r, that is

$$\phi(r) \sum_{d \mid r} d\mu\left(\frac{r}{d}\right)\frac{1}{\phi(d)} = \sum_{d \mid r} d\mu\left(\frac{r}{d}\right)\phi\left(\frac{r}{d}\right) = r \sum_{d \mid r} \mu(d)\frac{\phi(d)}{d} = 1.$$

Let (r, n) be

$$(r, n) = q_1 q_2 \cdots q_k \qquad (q_1, \cdots, q_k \text{ distinct primes}). \tag{5}$$

Then

$$\phi(r) \sum_{\substack{d \mid r \\ (d,n)=1}} d\mu\left(\frac{r}{d}\right)\frac{1}{\phi(d)} = \phi(r)\left[\sum_{d \mid r} - \sum_{q \mid (r,n)} \sum_{\substack{d \mid r \\ q \mid d}} + \cdots\right]. \tag{6}$$

By (4)

$$\phi(r) \sum_{\substack{d \mid r \\ c \mid d}} d\mu\left(\frac{r}{d}\right)\frac{1}{\phi(d)} = \phi(r) \sum_{d \mid (r/c)} cd\mu\left(\frac{r}{cd}\right)\frac{1}{\phi(c)\phi(d)} = c;$$

hence, by (6)

$$\phi(r) \sum_{\substack{d \mid r \\ (d,n)=1}} d\mu\left(\frac{r}{d}\right)\frac{1}{\phi(d)} = 1 - q_1 - q_2 - \cdots - q_k + q_1q_2 + q_1q_3 + \cdots$$

$$= \prod_{j=1}^{k} (1 - q_j),$$

which is equal to the right side of (1) and our proof is complete.

THE VANDERMONDE MATRIX

ALLEN KLINGER, The RAND Corporation, Santa Monica, California

1. The explicit representation of the inverse to Vandermonde's matrix seems unavailable in the mathematical literature and generally inaccessible, though simple in form. Inverting this matrix is necessary in many areas of numerical analysis (in exponential approximation and quadrature sums, in addition to the applications we will present). The material which follows outlines a derivation for the inverse and relates matrices of Vandermonde-form to polynomial interpolation and least-square fitting of data, in a way suitable for classroom exercises.

The $n \times n$ Vandermonde matrix V is given by

$$V = \begin{bmatrix} 1 & t_1 & t_1^2 & \cdots & t_1^{n-1} \\ \cdot & \cdot & \cdot & \cdots & \cdot \\ 1 & t_n & t_n^2 & \cdots & t_n^{n-1} \end{bmatrix} = [t_i^{j-1}]. \tag{1}$$

There are two well-known facts concerning V which appear in texts on matrix theory ([7] pp. 78 and 80; [1] p. 186):

(2) V is nonsingular if $\{t_i\}_{i=1}^{n}$ are distinct;

(3) $$\det V = \prod_{n \geq j > i \geq 1} (t_j - t_i).$$

As a consequence of (2), an equation with m distinct specified roots, $\{r_i\}_{i=1}^{m}$, can be written

(4) $$\det \begin{bmatrix} 1 & r_1 & r_1^2 & \cdots & r_1^m \\ \cdot & \cdot & \cdot & \cdots & \cdot \\ 1 & r_m & r_m^2 & \cdots & r_m^m \\ 1 & x & x^2 & \cdots & x^m \end{bmatrix} = 0.$$

2. Inverse of the Vandermonde matrix. The determinant formed from an $n \times n$ Vandermonde determinant, det V, by deleting the $(k+1)$-th column (kth powers) and adjoining as a new nth column the nth powers of the t_i, det V_k, satisfies

(5) $$\det V_k = (a_{n-k})(\det V),$$

where a_{n-k}, is the $(n-k)$-th elementary symmetric function of the n values of t_i ([2] pp. 144–145; [8] p. 99). a_r is the coefficient of y^{n-r} in the expansion of $\prod_{s=1}^{n}(y+t_s)$; thus

$$a_r = \sum_{1 \leq s_1 < s_2 < \cdots < s_r \leq n} \prod_{q=1}^{r} t_{s_q}.$$

Let a_{n-k}^{i} be the $(n-k)$-th elementary symmetric function of the $(n-1)$ arguments t_l, $l=1, 2, \cdots, n$, $l \neq i$.

Making use of (3), (5), and noting that the cofactors appearing in the expression for the inverse matrix are $(n-1) \times (n-1)$ determinants of the same form as det V_k, leads to

(6) $$V^{-1} = \left[\frac{(-1)^{i+j} a_{n-j}^{i}}{\prod_{k=i+1}^{n} (t_k - t_i) \prod_{l=1}^{i-1} (t_i - t_l)} \right]^T,$$

where T denotes transpose. With $\sum_{i=1}^{n_j} a_i$ for $\sum_{i=1, i \neq j}^{n} a_i$ and $\prod_{i=1}^{n_j} a_i$ for $\prod_{i=1, i \neq j}^{n} a_i$, equation (6) can easily be rewritten as

(7) $$V^{-1} = \left[\frac{(-1)^{i+1} \sum_{1 \leq s_1 < s_2 < \cdots < s_{n-i} \leq n}^{j} \prod_{q=1}^{n-i} t_{s_q}}{\prod_{k=1}^{n_j} (t_k - t_j)} \right].$$

(This result appears, without proof, in [4] p. 312.) The inverse for the special case $t_i = x + ih$, $i=0, 1, \cdots, n-1$, and an outline of an alternate derivation of

the inverse for the general Vandermonde matrix (but not the explicit representation of V^{-1}) may be found in [5].

3. Rectangular Vandermonde matrices. The concept of Vandermonde matrices generalizes to the rectangular case. Thus, we define

$$V_{nm} = \begin{bmatrix} 1 & t_1 & \cdots & t_1^{m-1} \\ 1 & t_2 & \cdots & t_2^{m-1} \\ \cdot & \cdot & \cdots & \cdot \\ 1 & t_n & \cdots & t_n^{m-1} \end{bmatrix} = [\mathbf{T}_1\mathbf{T}_2 \cdots \mathbf{T}_n]^T, \tag{8}$$

where $n \neq m$ and $\mathbf{T}_i$ is the vector

$$\mathbf{T}_i = [1, t_i, t_i^2, \cdots, t_i^{m-1}]^T, \qquad i = 1, \cdots, n. \tag{9}$$

Now put $\mathbf{U} = [u_i] = [u(t_i)]$ for brevity. If we seek an $(m-1)$-th degree polynomial which yields a least squares fit to $\{u_i\}_{i=1}^n$, we want an m-dimensional constant vector $\mathbf{C}$, such that $\mathbf{C}$ attains

$$\operatorname*{Min}_{\mathbf{C}} \sum_{i=1}^{n} (u_i - \mathbf{C}^T\mathbf{T}_i)^2. \tag{10}$$

Then, the usual procedure of differentiation with respect to the components of $\mathbf{C}$, and equating the resulting expressions to zero to obtain the normal equations ([6] pp. 343–355), yields a result which may easily be expressed by means of a rectangular Vandermonde matrix

$$V_{nm}^T V_{nm}\mathbf{C} = V_{nm}^T\mathbf{U}. \tag{11}$$

4. Interpolating polynomials. The interpolating polynomial through $(t_i, u(t_i))$, $i = 1, 2, \cdots, n$ is ([3] p. 193):

$$P(t) = \sum_{i=1}^{n} \frac{\omega(t)}{(t - t_i)\omega'(t_i)} u(t_i) = \sum_{i=1}^{n} u(t_i) \prod_{j=1}^{ni} \frac{t - t_j}{t_i - t_j} = \mathbf{L}^T\mathbf{U}, \tag{12}$$

where prime signifies derivative with respect to t,

$$\mathbf{L} = \left[\prod_{j=1}^{ni} \frac{t - t_j}{t_i - t_j} \right]^T, \text{ and } \omega(t) = \prod_{j=1}^{n} (t - t_j).$$

By setting $m = n$ in (11) we can obtain a matrix expression for this polynomial:

$$P(t) = [V_{nn}^{-1}\mathbf{U}]^T\mathbf{T} = \mathbf{T}^T V_{nn}^{-1}\mathbf{U}. \tag{13}$$

That $\mathbf{L}^T \equiv \mathbf{T}^T V_{nn}^{-1}$ is easily established by use of (6) or (7).

Any views expressed in this paper are those of the author. They should not be interpreted as reflecting the views of the RAND Corporation or the official opinion or policy of any of its governmental or private research sponsors.

A GENERALIZATION OF HJEMSLEV'S THEOREM

P. C. JOSEPH, St. Thomas College, Palai, India

Hjemslev's Theorem [1, p. 47; 2, p. 268] states that, in the Euclidean plane, when all the points P on one line are related by an isometry to all the points P' on another, the midpoints of the segments PP' are distinct and collinear or they all coincide.

A natural generalization is the following

THEOREM. *If S, S' are two figures in a plane, which are congruent (related by an isometry) and X is the midpoint of the segment joining any point P in S to the corresponding point P' in S', then the set of points X either all coincide or are collinear or they form a figure similar to S and S'.*

The proof is an application of Coxeter [1, p. 46, 3.51]: Any direct isometry is either a translation or a rotation. Any opposite isometry is either a reflection or a glide reflection.

Suppose, first, that the figures S, S' are two triangles ABC, $A'B'C'$.

(1) If the isometry is opposite, the midpoints X all lie on the line which is the mirror of the reflection or glide reflection.

(2) If the isometry is direct and is a translation, it is immediately evident that the figure formed by the points X is congruent (therefore certainly similar) to S, being related to S by a translation through half the displacement of the original translation.

(3) The only remaining possibility is a rotation about some point O through an angle α. If $\alpha=\pi$, the points X all coincide at O. Otherwise, we can choose the sense of rotation suitably so that $\alpha<\pi$.

If X, Y are the midpoints of AA', BB', it is easy to see that $OX=OA\cos(\alpha/2)$, $OY=OB\cos(\alpha/2)$, $\angle XOY=\angle AOB$. It follows that $XY=AB\cos(\alpha/2)$.

This relation holds for any two of the points A, B, C and leads to the conclusion that the triangles XYZ and ABC are similar.

The extension to any two congruent figures S, S' is immediate and this completes the proof.

The following concrete interpretation of the theorem is interesting.

If two identical maps of a country, drawn on transparent sheets, be thrown at random on a plane floor, the midpoints of the segments joining corresponding places on the two maps will either (A) be all collinear or (B) form a map of the same country, not bigger than the original, the possibility that the new map collapses into a single point being included.

(A) occurs if the two maps fall different sides up and (B) if both have the same side up.

Editorial Note. Before Julius Petersen changed his name to Hjelmslev, he discovered the "Petersen-Schoute Theorem" [3, p. 74], which shows that the same conclusion can be obtained if S and S', instead of being congruent, are directly similar.

A NOTE ON HERMITIAN FORMS

RABE VON RANDOW, Otago University, Dunedin, New Zealand

Introduction. It is well known that the standard form of a quadratic form f on a finite-dimensional vector space over (a) the field R of real numbers and (b) the field C of complex numbers is (a) $f(x) = \sum_1^p \xi_i^2 - \sum_{p+1}^r \xi_i^2$, where r is the rank and $2p-r$ is the signature of f, and (b) $f(x) = \sum_1^r \xi_i^2$, where r is the rank of f, and that the standard form of a hermitian form f on a finite-dimensional vector space over C is

$$f(x) = \sum_1^p |\xi_i|^2 - \sum_{p+1}^r |\xi_i|^2,$$

where again, r is the rank and $2p-r$ the signature of f. In fact, the theory of hermitian forms over C is completely analogous to that of quadratic forms over R, which, upon extension of the scalar field, gives rise to the theory of quadratic forms over C. Thus the following question presents itself: is it possible to develop a theory of hermitian forms over some division algebra containing C, which is completely analogous to that of quadratic forms over C? Now it is known that the only division algebras over R are C (cf. [1]), and the skew-field H of quaternions (cf. [2]). In this note we give a definition of hermitian forms over H answering the above question. The usual theory of hermitian forms over H utilizing the ordinary conjugation of quaternions is again analogous to that of quadratic forms over R, but a repetition of the above question at this level

obviously leads no further, as no other division algebras are available. We may summarize the situation schematically as follows:

$$\begin{array}{ccc} \text{(Quadratic Forms over } R) & \longrightarrow & \text{(Quadratic Forms over } C) \\ \text{analogous to} & & \text{analogous to} \\ \text{(Hermitian Forms over } C) & \longrightarrow & \text{(Hermitian Forms over } H) \\ \text{analogous to} & & \text{(to be defined)} \\ \text{(Usual Hermitian Forms over } H) & & \end{array}$$

The theory of hermitian forms differs essentially from that of quadratic forms in that it involves an involutory antiautomorphism of the scalar field. Furthermore, extra care is needed, as we are dealing with a skew-field. Let V be an n-dimensional (right) vector space over K, where K denotes C or H, let ϕ be a map $V\times V\to K$, and let $\alpha\to\bar{\alpha}$, $\alpha\in K$, be an involutory antiautomorphism of K, i.e., an automorphism of the vector space K over R satisfying $\overline{\alpha\beta}=\bar{\beta}\cdot\bar{\alpha}$ and $\bar{\bar{\alpha}}=\alpha$, $\alpha, \beta\in K$.

DEFINITION. *ϕ is a (left) sesquilinear form over K if*

$$\begin{aligned} \phi(x_1+x_2, y) &= \phi(x_1, y)+\phi(x_2, y), \quad (x_1, x_2, y\in V), \\ \phi(x, y_1+y_2) &= \phi(x, y_1)+\phi(x, y_2), \quad (x, y_1, y_2\in V), \\ \phi(x\alpha, y) &= \bar{\alpha}\cdot\phi(x, y), \quad (x, y\in V, \alpha\in K), \\ \phi(x, y\beta) &= \phi(x, y)\cdot\beta, \quad (x, y\in V, \beta\in K). \end{aligned}$$

ϕ is hermitian if $\phi(y, x)=\overline{\phi(x, y)}$, $x, y\in V$.

A few moments' trial and error using $\phi(x\alpha\beta, y)$, and $\phi(x\alpha, y\beta)$ in the last relation, show that $\alpha\to\bar{\alpha}$ must be an involutory antiautomorphism and that, apart from interchanging left and right throughout, the above definition is the only sensible one.

With a fixed basis (x_i) in V, we have a 1-1 correspondence between the set of hermitian sesquilinear forms over K and the set of hermitian $(n\times n)$-matrices over K (a square matrix (a_{ij}) over K is *hermitian* if $a_{ij}=\overline{a_{ji}}$ for all i, j): if $x=\sum x_i\xi_i$, $y=\sum x_j\eta_j$, then $\phi(x, y)=\sum\sum\xi_i\cdot\phi(x_i, x_j)\cdot\eta_j=\underline{\xi}^*\cdot M_\phi\cdot\underline{\eta}$ in the usual vector notation, where $M_\phi=(\phi(x_i, x_j))$ is the matrix of ϕ.

DEFINITION. *Take a fixed basis (x_i) in V. Then a hermitian form f over K is a map $V\to K$ given by a hermitian $(n\times n)$-matrix A over K: $f(x)=\underline{\xi}^*\cdot A\cdot\underline{\xi}$, where $x=\sum x_i\xi_i$.*

For the fields dealt with here, we have a 1-1 correspondence between the set of hermitian forms over K and the set of hermitian $(n\times n)$-matrices over K.

We now have to fix the involutory antiautomorphisms to be considered. For $K=C$, it follows readily from the relations $\bar{1}=1$ and $(\bar{i})^2=-1$, that the usual conjugation $z=x+yi\to\bar{z}=x-yi$ is the only involutory (anti)automorphism apart from the identity map. For $K=H$, it has been shown in [3] that, up to

change of basis in H, there are only two involutory antiautomorphisms, namely

$$q = a + bi + cj + dk \to a - bi - cj - dk,$$
$$q = a + bi + cj + dk \to a - bi + cj + dk,\ q \in H.$$

The first of these is the usual conjugation of quaternions, and its use would give the usual theory of real-valued hermitian forms over H. For our purposes we define $\bar{q}=a-bi+cj+dk$. Furthermore, we embed C in H by means of the monomorphism ν: $x+yi\to x+yi+0j+0k$, and it follows that $\overline{\nu(z)}=\nu(\bar{z})$. Note that if $K=C$, $f(x)$ is real for all $x\in V$, i.e., $f(x)\in\{z\in C\,|\,z=\bar{z}\}$, and if $K=H$, $f(x)\in N=\{q\in H\,|\,q=\bar{q}\}$ for all $x\in V$. This is similar to the situation in quadratic form theory: a quadratic form over R is real-valued, whereas a quadratic form over C is complex-valued.

THEOREM. *Given a hermitian form f over K, there exists a basis for V such that $f(x)=\sum_1^r \bar{\eta}_i c_i \eta_i$, where the $c_i\in R-\{0\}$ if $K=C$ and the $c_i\in N-\{0\}$ if $K=H$, and r is the rank of f.*

The proof for $K=C$ is standard (cf. [4]), and is readily adapted to the case $K=H$.

COROLLARY 1. *If $K=C$, f can be reduced further to the form $f(x)=\sum_1^p |\eta_i|^2 - \sum_{p+1}^r |\eta_i|^2$.*

The proof is again standard (cf. [4]), and furthermore, the Sylvester law of inertia holds for hermitian forms over C, i.e., two hermitian forms over C are equivalent if and only if they have the same rank and signature.

COROLLARY 2. *If $K=H$, f can be reduced further to the form $f(x)=\sum_1^r \bar{\eta}_i\cdot\eta_i$. Hence two hermitian forms over H are equivalent if and only if they have the same rank.*

Proof. We need only prove that for each $c_i\in N-\{0\}$, $\exists q_i\in H-\{0\}$ such that $\bar{q}_i c_i q_i=1$. We will prove the following stronger result: given $q'\in N-\{0\}$, $\exists q\in N-\{0\}$ such that $q'=q\bar{q}$.

Let $q'=\alpha+\zeta j$, $\alpha\in R$, $\zeta\in C$, and set $q=a+zj$, $a\in R$, $z\in C$. Then $q\bar{q}=q^2=(a^2-|z|^2)+2azj=q'$ gives $\alpha=a^2-|z|^2$ and $\zeta=2az$.

Clearly $a=0$ if and only if $\zeta=0$ and $\alpha<0$, i.e., $q'\in R$ and $q'<0$. In this case $|z|=\sqrt{-\alpha}$, hence we choose $z=\sqrt{-\alpha}$, i.e., $q=\sqrt{-\alpha}\cdot j$.

For all other q', $a\neq 0$. Then $z=\zeta/2a$, hence $\alpha=a^2-|\zeta|^2/4a^2$ or $4a^4-4\alpha a^2-|\zeta|^2=0$. Solving for a (which is real), we get $a=\pm\sqrt{\tfrac{1}{2}\{\alpha+\sqrt{(\alpha^2+|\zeta|^2)}\}}$ and $z=\zeta/2a$ in this case.

FUNCTIONS SATISFYING A CERTAIN TYPE OF RECIPROCITY OF DERIVATIVES

C. J. BROOKES, University of Aston, Birmingham, England

Although in general

$$\frac{d^n y}{dx^n} \neq \frac{1}{d^n x/dy^n}, \quad n \geqq 2,$$

it can be shown that a particular solution of the family of nonlinear differential equations

$$\frac{d^n y}{dx^n} = \frac{1}{d^n x/dy^n}$$

is the family of rectangular hyperbolae

$$(x + a)(y + b) = (n!)^{2/(n-1)}$$

where a and b are arbitrary constants.

Moreover, the procedure involved also leads to a particular solution of the more general equation

$$\frac{d^n y}{dx^n} \cdot \frac{d^m x}{dy^m} = 1, \quad n \geqq 2, m \geqq 2,$$

in the form

$$(x + a)^{n-1}(y + b)^{m-1} = (-1)^{n+m} \frac{\Gamma((nm - 1)/(n - 1))\Gamma((nm - 1)/(m - 1))}{\Gamma((n - 1)/(m - 1))\Gamma((m - 1)/(n - 1))}.$$

Γ signifying the usual gamma function.

Proof. Consider first the case $n=2$, i.e.

$$\frac{d^2 y}{dx^2} \cdot \frac{d^2 x}{dy^2} = 1.$$

With $p=dy/dx$, $d^2y/dx^2=p(dp/dy)$ and $d^2x/dy^2=-(1/p^2)dp/dy$, the equation can be solved to give $(x+a)(y+b)=4$, where a and b are arbitrary constants.

General solutions for $n \geqq 3$, however, are extremely difficult, if not impossible, to determine. For example consider $n=3$, i.e.,

$$\frac{d^3 y}{dx^3} \cdot \frac{d^3 x}{dy^3} = 1. \tag{1}$$

With $p=(dy/dx)$, as before, we find that equation (1) reduces to:

$$\left\{\left(\frac{dp}{dy}\right)^2 + p\frac{d^2p}{dy^2}\right\}\left\{2\left(\frac{dp}{dy}\right)^2 - p\frac{d^2p}{dy^2}\right\} = p^2.$$

With $u=dp/dy$ and $d^2p/dy^2=u(du/dp)$, this equation reduces to:

$$u^2p^2\left(\frac{du}{dp}\right)^2 - u^3p\left(\frac{du}{dp}\right) + (p^2 - 2u^4) = 0.$$

With $p=z^2$ and $u=rz$, we obtain $3r^2 \pm \sqrt{(9r^4-4)} = a_1z^6$ or a_2/z^6 where a_1, a_2 are constants.

Reverting to the original variables p and y, the equations become:

$$\frac{dp}{dy} = \pm \frac{\sqrt{(a_1^2p^6 + 4)}}{p\sqrt{(6a_1)}}, \qquad \frac{dp}{dy} = \pm \frac{\sqrt{(a_2^2 + 4p^6)}}{p\sqrt{(6a_2)}}$$

solutions of which lead to transcendental equations in (dy/dx) in terms of elliptic integrals. Further progress seems impossible.

From symmetry, however, it is suggested that a particular solution to the general equation

$$\frac{d^ny}{dx^n}\cdot\frac{d^nx}{dy^n} = 1 \tag{2}$$

might take the form

$$(x + a)(y + b) = k, \tag{3}$$

where k is to be determined. From (3) it can be seen that

$$\frac{d^ny}{dx^n} = \frac{(-1)^nk(n!)}{(x + a)^{n+1}}, \qquad \frac{d^nx}{dy^n} = \frac{(-1)^nk(n!)}{(y + b)^{n+1}}.$$

Equations (2) and (3) now give

$$\frac{d^ny}{dx^n}\cdot\frac{d^nx}{dy^n} = \frac{k^2(n!)^2}{(x + a)^{n+1}(y + b)^{n+1}} = \frac{(n!)^2}{k^{n-1}}.$$

Choosing $k=(n!)^{2/n-1}$, $n\geqq 2$, gives the required result.

Now consider the equation

$$\frac{d^ny}{dx^n}\cdot\frac{d^mx}{dy^m} = 1 \tag{4}$$

and suppose that

$$(x + a)^\alpha(y + b)^\beta = k \tag{5}$$

where α, β and k are to be determined. From equation (5) we find that
